- 185. SH + N₂O.** The recommendation is the upper limit rate constant reported by Herndon et al.¹ (298 K). As discussed by Herndon et al., the much greater (four orders of magnitude) rate constant reported by Ravichandran et al.² appears to result from mis-interpretation of the source of electronically excited HSO, chemiluminescence from which was employed by Ravichandran et al. to follow the reaction kinetics. (Table: 06-02, Note: 06-02, Evaluated: 06-2) [Back to Table](#)
- (1) Herndon, S. C.; Froyd, K. D.; Lovejoy, E. R.; Ravishankara, A. R. How rapidly does the SH radical react with N₂O? *J. Phys. Chem. A* **1999**, *103*, 6778-6785, doi:10.1021/jp9911853.

- 186. SH + Cl₂.** The recommended *k*(298 K) is the average of the one reported by Nesbitt and Leone² (298 K), who studied the kinetics of the Cl + H₂S → SH + HCl, SH + Cl₂ → ClSH + Cl chain reaction using a laser flash photolysis – IR emission technique, and the one reported by Fenter and Anderson,¹ who employed a discharge flow – laser induced fluorescence technique to study the SD + Cl₂ reaction over the temperature range 273–373 K; the Fenter and Anderson results are corrected for the secondary kinetic isotope effect using the theoretical results of Wang et al.,³ who report *k_H/k_D* = 1.11 exp(–71/T). The recommended value for *E/R* is taken from the work of Fenter and Anderson corrected as described above for the secondary kinetic isotope effect. The recommended value for the parameter *g* reflects the absence of confirming studies. (Table: 19-5, Note: 19-5, Evaluated: 19-5) [Back to Table](#)
- (1) Fenter, F. F.; Anderson, J. G. Kinetics and mechanism of the reactions of the SD Radical with Br₂, BrCl, Cl₂, and F₂. *J. Phys. Chem.* **1991**, *95*, 3172-3180, doi:10.1021/j100161a041.
 - (2) Nesbitt, D. J.; Leone, S. R. Laser-initiated chemical chain reactions. *J. Chem. Phys.* **1980**, *72*, 1722-1732, doi:10.1063/1.439284.

- 187. SH + BrCl; SH + Br₂; SH + F₂.** The recommendations for these reactions are derived from the experimental data of Fenter and Anderson¹ for the SD reactions corrected for the secondary kinetic isotope effect using the theoretical results of Wang et al.^{2,3} Wang et al. report *k_H/k_D* = 0.81 exp(–50/T) for BrCl and 1.08 exp(–49/T) for Br₂;² their results for SH(SD) + F₂ suggest that *k_H/k_D* = 1.036, 1.048, and 1.056 at 298 K, 338 K, and 373 K, respectively,³ the three temperatures where experimental SD rate constants are reported by Fenter and Anderson. The recommended uncertainties have been increased over those estimated by Fenter and Anderson to reflect the absence of any confirming investigations as well as uncertainty in the theoretical secondary kinetic isotope effects. For the SD + BrCl reaction, the channel producing ClSD + Br is reported by Fenter and Anderson to be described by the rate expression *k* = 2.3 × 10^{–11} exp(+100/T) cm³ molecule^{–1} s^{–1}, thereby accounting for 43% of overall reactivity at 298 K and 51% at 373 K. On the other hand, Wang et al.² predict theoretically that reaction proceeds almost exclusively to produce BrSD (BrSH) + Cl products at atmospheric temperatures, with the ClSD (ClSH) + Br channel becoming important only at higher temperatures. (Table: 19-5, Note: 19-5, Evaluated: 19-5) [Back to Table](#)

188. HSO + O₂. This recommendation is based on the study by Lovejoy et al.² (296 K), who employed laser magnetic resonance monitoring of HSO in a discharge flow system. The upper limit thus derived for $k(298\text{ K})$ is nearly two orders of magnitude smaller than measured by Bulatov et al.¹ (Table: 92-20, Note: 92-20, Evaluated: 92-20) [Back to Table](#)

- (1) Bulatov, V. P.; Sarkisov, O. M.; Kozliner, M. Z.; Ergorov, V. G. Mechanism of hydrogen sulfide photooxidation in atmosphere. *Khim. Fiz.* **1986**, *5*, 1031-1036.

189. HSO + O₃. This recommended $k(298\text{ K})$ is based on the determinations by Friedl et al.¹ (298 K) and Wang and Howard³ (296–405 K). In the first study, performed at higher O₃ concentrations, greater quantities of HSO were produced in the flow tube and SH approached a steady state due to its generation via HSO + O₃. The rate constant for this reaction was thus determined relative to SH + O₃ from measurements of the steady state SH concentration as a function of the initial SH concentration. In the second study, the rate constant and its branching ratio were measured at two temperatures. At room temperature, the overall rate constant is in excellent agreement with that of Friedl et al. More recently, Lee et al.² (273–423 K) determined a room temperature rate constant of $4.7 \times 10^{-14}\text{ cm}^3\text{ molecule}^{-1}\text{ s}^{-1}$ for the sum of all reaction channels not producing HS. This value is approximately 30% greater than that measured by Wang and Howard for the same channels. Lee et al. derive an Arrhenius activation energy of 1120 K for these channels from data between 273 and 423 K, in agreement with the more limited temperature-dependent data of Wang and Howard.

The lack of an isotope effect when SD was employed in the Friedl et al. study suggests that the products of the HSO + O₃ reaction are SH + 2O₂ (analogous to those for HO₂ + O₃). However, Wang and Howard found that only 70% of the reaction leads to HS formation. In addition, their observations of HO₂ production in the presence of O₂ suggests the existence of a reaction channel producing HSO₂ + O₂ followed by HSO₂ + O₂ → HO₂ + SO₂. At the present time, no recommendation is given for the product channels. Further mechanistic work is suggested, since it is important to understand whether this reaction in the atmosphere leads to HS regeneration or to oxidation of the sulfur.

190. HSO + NO; HSO + NO₂. The recommendations for these reactions are based on the study by Lovejoy et al.³ (296 K) in which laser magnetic resonance was used to monitor HSO in a discharge flow system. Their upper limit for the NO reaction is a factor of 25 smaller than the rate constant measured by Bulatov et al.² using intracavity laser absorption at pressures between 10 and 100 Torr. Since it is unlikely that this reaction rate undergoes a factor of 25 increase between 1 Torr (the pressure of the Lovejoy et al. work) and 10 Torr, the higher rate constant may be due to secondary chemistry associated with the HSO production methods employed.

The recommendation for the NO₂ reaction is a factor of 2 higher than the rate constant reported by Bulatov et al.¹ Lovejoy et al. have attributed this difference to HSO regeneration under the experimental conditions used by Bulatov et al.¹ The product assignment for this reaction is discussed in the note for the HSO₂ + O₂ reaction. (Table 87-41, Note: 87-41, Evaluated: 87-41) [Back to Table](#)

191. HSO₂ + O₂. This recommendation is based on the rate of HO₂ formation measured by Lovejoy et al.¹ (296 K) upon addition of O₂ to the HSO + NO₂ reaction system. While HSO₂ was not observed directly, a consideration

of the mechanistic possibilities for $\text{HSO} + \text{NO}_2$, coupled with measurements of the HO_2 production rate at various O_2 pressures, led these authors to suggest that HSO_2 is both a major product of the $\text{HSO} + \text{NO}_2$ reaction and a precursor for HO_2 via reaction with O_2 .

(Table: 87-41, Note: 87-41, Evaluated: 87-41) [Back to Table](#)

- (1) Lovejoy, E. R.; Wang, N. S.; Howard, C. J. Kinetic studies of the reactions of HSO with NO_2 , NO , and O_2 . *J. Phys. Chem.* **1987**, *91*, 5749-5755, doi:10.1021/j100306a046.

I92. $\text{HOSO}_2 + \text{O}_2$. This recommendation is based on the studies of Gleason et al.³ (298 K) and Gleason and Howard² (297–423 K) in which the HOSO_2 reactant was monitored using a chemical ionization mass spectrometric technique. Gleason and Howard is the only temperature dependence investigation, and these authors report the same 297 K rate coefficient as the one reported by Gleason et al. The recommended uncertainty parameter g is increased from the E/R error limits quoted by Gleason and Howard to account for potential uncertainties in extrapolating their data to sub-ambient temperatures. The recommended value of $k(298 \text{ K})$ derives further support from the studies of Margitan⁶ (298 K) and Martin et al.⁷ (298 K), both of whom used modeling fits of OH radical decays in the $\text{OH} + \text{SO}_2 + \text{M}$ reaction system in the presence of O_2 and NO . In this latter analysis, the HOSO_2 reacts with O_2 , yielding HO_2 , which subsequently regenerates OH through its reaction with NO . Theoretical electronic structure and kinetics calculations by Huynh and coworkers⁵ provides additional support for the recommendation. The infrared spectrum of HOSO_2 has been recorded in low temperature matrix isolation experiments by Hashimoto et al.⁴ and Nagase et al.⁸ Mass spectrometric detection of HOSO_2 in the gas phase has also been reported by Egsgaard et al.¹

I93. $\text{CS} + \text{O}_2$. The recommendation for $k(298 \text{ K})$ is based on the work of Black et al.¹ (298 K) using laser induced fluorescence to monitor CS . This value agrees with the somewhat less precise determination by Richardson² (293, 495 K) using OCS formation rates. The latter author presents evidence that this reaction channel dominates over the one producing $\text{SO} + \text{CO}$ by more than a factor of 10. Measurements by Richardson at 293 and 495 K yield an E/R of 1860 K. However, use of this activation energy with the recommended value of $k(298 \text{ K})$ results in an unusually low Arrhenius A -factor of $1.5 \times 10^{-16} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$. In view of this, no recommendation is given for the temperature dependence.

(Table: 85-37, Note: 85-37, Evaluated: 85-37) [Back to Table](#)

- (1) Black, G.; Jusinski, L. E.; Slinger, T. G. Rate coefficients for CS reactions with O_2 , O_3 and NO_2 at 298 K. *Chem. Phys. Lett.* **1983**, *102*, 64-68, doi:10.1016/0009-2614(83)80659-9.

I94. $\text{CS} + \text{O}_3$; $\text{CS} + \text{NO}_2$. The $k(298 \text{ K})$ recommendations for both reactions accept the results of Black et al.¹ (298 K), who used laser-induced fluorescence to monitor the CS reactant. The uncertainty factors reflect the absence of any confirming measurements.

(Table: 85-37, Note: 85-37, Evaluated: 85-37) [Back to Table](#)

- (1) Black, G.; Jusinski, L. E.; Slinger, T. G. Rate coefficients for CS reactions with O₂, O₃ and NO₂ at 298 K. *Chem. Phys. Lett.* **1983**, *102*, 64-68, doi:10.1016/0009-2614(83)80659-9.
- 195. CH₃S + O₂.** This upper limit is based on the study by Tyndall and Ravishankara³ (298 K). Somewhat higher upper limits were derived in the earlier studies of Balla et al.¹ (298 K) and Black and Jusinski.² (Table: 90-1, Note: 90-1, Evaluated: 90-1) [Back to Table](#)
- (1) Balla, R. J.; Nelson, H. H.; McDonald, J. R. Kintics of the reaction of CH₃S with NO, NO₂ and O₂. *Chem. Phys.* **1986**, *109*, 101-107, doi:10.1016/0301-0104(86)80188-4.
- (2) Black, G.; Jusinski, L. E. Laser-induced fluorescence studies of the CH₃S radical. *J. Chem. Soc. Faraday Trans. 2* **1986**, *86*, 2143-2151, doi:10.1039/f29868202143.
- (3) Tyndall, G. S.; Ravishankara, A. R. Kinetics and mechanism of the reactions of CH₃S with O₂ and NO₂ at 298 K. *J. Phys. Chem.* **1989**, *93*, 2426-2435, doi:10.1021/j100343a041.
- 196. CH₃S + O₃.** The recommendation for *k*(298 K) is the average of room temperature rate constants reported by Tyndall and Ravishankara⁵ (298 K), Domine et al.² (300 K), Turnipseed et al.⁴ (295–359 K), and Martinez et al.³ (259–381 K). The recommendation for *E*/*R* is the average of values obtained from least squares fits of the temperature-dependent data of Turnipseed et al. and Martinez et al. using only rate constants at temperatures below 345 K. A failure to observe significant reaction in the study by Black and Jusinski¹ is interpreted as due to rapid regeneration of CH₃S in their system. Tyndall and Ravishankara⁵ corrected their measured 298 K rate constant downward by ~20% to account for CH₃S regeneration via the CH₃SO + O₃ reaction, but the magnitude of the correction is now highly uncertain in light of the results of Domine et al. and Turnipseed et al. Domine et al. measured the yield of CH₃SO to be 15%. (Table: 06-2, Note: 06-2, Evaluated: 06-2) [Back to Table](#)
- (1) Black, G.; Jusinski, L. E. Laser-induced fluorescence studies of the CH₃S radical. *J. Chem. Soc. Faraday Trans. 2* **1986**, *86*, 2143-2151, doi:10.1039/f29868202143.

- (4) Turnipseed, A. A.; Barone, S. B.; Ravishankara, A. R. Reactions of CH₃S and CH₃SOO with O₃, NO₂, and NO. *J. Phys. Chem.* **1993**, *97*, 5926-5934, doi:10.1021/j100124a025.
- (5) Tyndall, G. S.; Ravishankara, A. R. Kinetics of the reaction of CH₃S with O₃ at 298 K. *J. Phys. Chem.* **1989**, *93*, 4707-4710, doi:10.1021/j100349a006.
- 197. CH₃S + NO.** The upper limit for the bimolecular reaction between CH₃S and NO is based on estimates by Balla et al.¹ (295–503 K), who conducted a temperature dependence study of the termolecular reaction. (Table: 92-20, Note: 92-20, Evaluated: 92-20) [Back to Table](#)
- (1) Balla, R. J.; Nelson, H. H.; McDonald, J. R. Kintics of the reaction of CH₃S with NO, NO₂ and O₂. *Chem. Phys.* **1986**, *109*, 101-107, doi:10.1016/0301-0104(86)80188-4.
- 198. CH₃S + NO₂.** The recommendation for *k*(298 K) is the average of room temperature rate constants reported by Tyndall and Ravishankara⁶ (298 K), Domine et al.³ (297 K), Turnipseed et al.⁵ (242–359 K), Martinez et al.⁴ (263–381 K), and Chang et al.² (222–420 K). The recommendation for *E*/*R* is the average of values reported by Turnipseed et al., Martinez et al., and Chang et al. An earlier study by Balla et al.¹ (295–511 K) appears to have been affected by secondary reactions resulting from high radical concentrations. Tyndall and Ravishankara determined the NO yield to be (80 ± 20)%. Together with the unity yield of CH₃SO obtained by Domine et al., this implies that the primary reaction channel is as written. - I99. CH₃S + CO.** The recommendation is based on the study of Koch et al.¹ (208–295 K), who generated CH₃S by laser flash photolysis of CH₃SSCH₃ and monitored the loss of CH₃S by laser induced fluorescence. The rate of loss of CH₃S was found to be independent of [CO] up to levels of approximately 10¹⁷ molecules cm⁻³. No enhancement of the CH₃S loss rate was observed when O₂ was added to the reaction mixture, confirming that CH₃SOO is also unreactive toward CO. Electronic structure calculations are consistent with experimental observations, suggesting that there is a significant barrier (~12 kJ mol⁻¹) to formation of a very weakly bound (~9 kJ mol⁻¹) CH₃S–CO adduct.

- I100. CH₃S + Br₂.** The recommendation is based on the study of Nicovich et al.¹ (298 K), who coupled laser flash photolysis of Br₂/CH₃SH/H₂/N₂ mixtures with resonance fluorescence detection of Br atoms to monitor the kinetics of Br approach to steady state (Br + CH₃SH → CH₃S + HBr; CH₃S + Br₂ → CH₃SBr + Br). The recommended uncertainty is larger than estimated by Nicovich et al. to reflect the slightly indirect nature of the rate constant determination and the lack of a confirming study.
(Table: 15-10, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

Heats of formation of SH and CH₃S radicals. *J. Phys. Chem.* **1992**, *96*, 2518-2528, doi:10.1021/j100185a025.
- I101. CH₂SH + O₂.** This recommended *k*(298 K) is the average of the rate constants obtained by Rahman et al.² (298 K) in a fast flow mass spectrometry system and Anastasi et al.¹ (298 K) using a pulse radiolysis – kinetic absorption apparatus. The value of Anastasi et al. is nearly twice that of Rahman et al. It is difficult at present to indicate a preference for the results of one study over the other, and the value of *f*(298 K) has been chosen to reflect this uncertainty. Since this is a fast bimolecular reaction, one would expect the products to be HO₂ + CH₂S, by analogy with the reaction between CH₂OH and O₂.

I104. CH₂SH + NO₂. The recommended $k(298\text{ K})$ is an average of the rate constants obtained by Rahman et al.² (298 K) in a fast flow mass spectrometry system and by Anastasi et al.¹ (298 K), using a pulse radiolysis kinetic absorption apparatus. The value of Rahman et al. is nearly twice that of Anastasi et al. It is difficult to indicate a preference for the results of one study over the other, and the value of $f(298\text{ K})$ has been chosen to reflect this uncertainty.

(Table: 94-26, Note: 94-26, Evaluated: 94-26) [Back to Table](#)

- (1) Anastasi, C.; Broomfield, M.; Nielsen, O. J.; Pagsberg, P. Kinetics and mechanisms of the reactions of CH₂SH radicals with O₂, NO, and NO₂. *J. Phys. Chem.* **1992**, *96*, 696-701, doi:10.1021/j100181a034.

I105. CH₃SO + O₃. The recommended $k(298\text{ K})$ is an average of values reported by Domine et al.² (300 K) and Borissenko et al.¹ (300 K). It is supported by the study of Tyndall and Ravishankara³ (298 K), in which the rate constant was derived from a complex analysis of the CH₃S + O₃ reaction system. Borissenko et al. measured the rate constant relative to the rate constant for the CH₃SO + NO₂ reaction; they report that the CH₃SO + NO₂ rate constant is greater by a factor of 47. Domine et al. place the direct yield of CH₂SO at approximately 10% and that of CH₃S at 13% at low pressure. Borissenko et al. report that the SO₂ yield is near unity in 100–600 Torr N₂.

(Table: 06-2, Note: 06-2, Evaluated: 06-2) [Back to Table](#)

- (1) Borissenko, D.; Kukui, A.; Laverdet, G.; Le Bras, G. Experimental study of SO₂ formation in the reactions of CH₃SO radical with NO₂ and O₃ in relation with the atmospheric oxidation mechanism of dimethyl sulfide. *J. Phys. Chem. A* **2003**, *107*, 1155-1161, doi:10.1021/jp021701g.
- (2) Domine, F.; Ravishankara, A. R.; Howard, C. J. Kinetics and mechanisms of the reactions of CH₃S, CH₃SO, and CH₃SS with O₃ at 300 K and low pressures. *J. Phys. Chem.* **1992**, *96*, 2171-2178, doi:10.1021/j100184a027.
- (3) Tyndall, G. S.; Ravishankara, A. R. Kinetics of the reaction of CH₃S with O₃ at 298 K. *J. Phys. Chem.* **1989**, *93*, 4707-4710, doi:10.1021/j100349a006.

I106. CH₃SO + NO₂. This recommendation is based on the direct measurements of Domine et al.² (297 K). The results are supported by somewhat less direct measurements of Tyndall and Ravishankara⁶ (298 K), Mellouki et al.⁵ (298 K), and Kukui et al.³ (300 K). The results of Kukui et al. suggest a small negative activation energy, but their data set is not extensive enough to warrant a recommendation for E/R without independent confirmation. Borissenko et al.¹ (298 K) report that the SO₂ yield drops from ~0.4 in 100 Torr N₂ to ~0.25 in 660 Torr N₂. A detailed theoretical singlet potential energy surface has been reported by Lesar.⁴

- (6) Tyndall, G. S.; Ravishankara, A. R. Kinetics and mechanism of the reactions of CH₃S with O₂ and NO₂ at 298 K. *J. Phys. Chem.* **1989**, *93*, 2426-2435, doi:10.1021/j100343a041.

I107. CH₃SOO + O₃, CH₃SOO + NO, CH₃SOO + NO₂. These recommendations are based on the experiments of Turnipseed et al.¹ in which CH₃S was monitored by laser induced fluorescence in equilibrium with CH₃SOO. The upper limit for the O₃ reaction was determined from experiments at 227 K. The results for the NO and NO₂ reactions were independent of temperature over the ranges 227–256 K and 227–246 K, respectively. The uncertainties placed on these recommendations have been increased over those estimated by the authors to reflect the absence of any confirming investigations.

(Table: 94-26, Note: 94-26, Evaluated: 94-26) [Back to Table](#)

- (1) Turnipseed, A. A.; Barone, S. B.; Ravishankara, A. R. Reactions of CH_3S and CH_3SOO with O_3 , NO_2 , and NO . *J. Phys. Chem.* **1993**, *97*, 5926-5934, doi:10.1021/j100124a025.

I108. $\text{CH}_3\text{SO}_2 + \text{NO}_2$. This recommendation is based on the study by Ray et al.¹ (298 K) using a discharge flow reactor equipped with laser induced fluorescence and mass spectrometric detection. The CH_3SO_2 was produced by the sequential oxidation of CH_3S and CH_3SO by NO_2 and is to be differentiated from the weakly bound adduct, CH_3SOO , formed by the reaction of CH_3S with O_2 at low temperature (Turnipseed et al.²). The uncertainty limit on the rate constant has been increased over that given by the authors to reflect the absence of any confirming investigation. However, some additional support for this recommendation does come from the study of the $\text{CH}_3\text{S} + \text{NO}_2$ reaction by Tyndall and Ravishankara.³ These authors observed fluorescence from a product species tentatively identified as CH_3SO_2 , produced by the reaction of CH_3SO with NO_2 . Computer simulation of the rise and fall of the fluorescence signal yielded an approximate rate constant value for the reaction $\text{CH}_3\text{SO}_2 + \text{NO}_2$ of $7.0 \times 10^{-12} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$. However, an unambiguous differentiation between the production and disappearance rate constants was not possible.

- (2) Turnipseed, A. A.; Barone, S. B.; Ravishankara, A. R. Reactions of CH_3S and CH_3SOO with O_3 , NO_2 , and NO . *J. Phys. Chem.* **1993**, *97*, 5926-5934, doi:10.1021/j100124a025.
- (3) Tyndall, G. S.; Ravishankara, A. R. Kinetics and mechanism of the reactions of CH_3S with O_2 and NO_2 at 298 K. *J. Phys. Chem.* **1989**, *93*, 2426-2435, doi:10.1021/j100343a041.

I109. $\text{CH}_3\text{SCH}_2 + \text{NO}_3$. The recommended k (298 K) is based on the experiments of Butkovskaya and Le Bras¹ (298 K). The uncertainty factor reflects the absence of any confirming investigation.

(Table: 94-26, Note: 94-26, Evaluated: 94-26) [Back to Table](#)

- (1) Butkovskaya, N. I.; Le Bras, G. Mechanism of the $\text{NO}_3 + \text{DMS}$ reaction by discharge flow mass spectrometry. *J. Phys. Chem.* **1994**, *98*, 2582-2591, doi:10.1021/j100061a014.

I110. $\text{CH}_3\text{SCH}_2\text{O}_2 + \text{NO}$. The recommended k (298 K) is based on the experiments of Urbanski et al.² (261–400 K), which are less impacted by secondary chemistry complications than the experiments of Wallington et al.³ (298 K) or Turnipseed et al.¹ (298 K); the error limits are chosen to encompass the rate constants reported in all three studies. The E/R value is taken from Urbanski et al., who report the only available temperature dependence data. The recommended value for the parameter g is larger than reported by Urbanski et al. pending independent confirmation of their result. Urbanski et al. observed that the reaction produces formaldehyde (H_2CO) with unit yield, suggesting that the $\text{CH}_3\text{SCH}_2\text{O}$ product rapidly decomposes to $\text{CH}_3\text{S} + \text{H}_2\text{CO}$.

Phys. Chem.* **1993**, *97*, 8442-8449, doi:10.1021/j100134a013.

I111. $\text{CH}_3\text{SCH}_2\text{O}_2 + \text{CH}_3\text{SCH}_2\text{O}_2$. The recommended k (298 K) is the average of values reported by Wallington et al.² (298 K) using a pulse radiolysis UV absorption technique and Urbanski et al.¹ (298 K) using a laser flash photolysis tunable diode laser absorption technique. Urbanski et al. observed that the reaction produces formaldehyde with unit yield, suggesting that the dominant reaction pathway is $2 \text{CH}_3\text{SCH}_2\text{O}_2 \rightarrow 2 \text{CH}_3\text{SCH}_2\text{O} + \text{O}_2$ ($\text{CH}_3\text{SCH}_2\text{O}$ rapidly decomposes to $\text{CH}_3\text{S} + \text{H}_2\text{CO}$).

- (2) Wallington, T. J.; Ellermann, T.; Nielsen, O. J. Atmospheric chemistry of dimethyl sulfide: UV spectra and self-reaction kinetics of CH_3SCH_2 and $\text{CH}_3\text{SCH}_2\text{O}_2$ radicals and kinetics of the reactions $\text{CH}_3\text{SCH}_2 + \text{O}_2 \rightarrow \text{CH}_3\text{SCH}_2\text{O}_2$ and $\text{CH}_3\text{SCH}_2\text{O}_2 + \text{NO} \rightarrow \text{CH}_3\text{SCH}_2\text{O} + \text{NO}_2$. *J. Phys. Chem.* **1993**, *97*, 8442-8449, doi:10.1021/j100134a013.

II12. $\text{CH}_3\text{SS} + \text{O}_3$. The recommended $k(298\text{ K})$ is based on the discharge flow photoionization mass spectrometry study by Domine et al.¹ (300 K). The uncertainty factor reflects the absence of any confirming investigations. The rate constant ratio for the reactions of CH_3SS with O_3 and NO_2 is consistent with the rate constant ratio for the corresponding CH_3S reactions.

(Table: 92-20, Note: 92-20, Evaluated: 92-20) [Back to Table](#)

- (1) Domine, F.; Ravishankara, A. R.; Howard, C. J. Kinetics and mechanisms of the reactions of CH_3S , CH_3SO , and CH_3SS with O_3 at 300 K and low pressures. *J. Phys. Chem.* **1992**, *96*, 2171-2178, doi:10.1021/j100184a027.

II13. $\text{CH}_3\text{SS} + \text{NO}_2$; $\text{CH}_3\text{SSO} + \text{NO}_2$. The recommended $k(298\text{ K})$ are based on the discharge flow photoionization mass spectrometry study by Domine et al.¹ (297 K). The rate constant ratio for these two reactions agrees with that observed for reactions of other RS/RSO radicals with NO_2 . The assigned uncertainties reflect this agreement but acknowledge the absence of any confirming investigation. In the Domine et al. study, CH_3SSO was produced by reacting away all CH_3SS with high NO_2 concentrations. Thus, as expected, O atom transfer may be the primary channel in the CH_3SS reaction.

1.15 Metal Reactions

1.15.1 Table 1J: Metal Reactions

Reaction	Temperature Range of Exp. Data (K) ^a	A-Factor	E/R	k(298 K) ^b	f(298 K) ^c	g ^c	Notes
$\text{Na} + \text{O}_2 \xrightarrow{\text{M}} \text{NaO}_2$		(See Table 2-1)					
$\text{Na} + \text{O}_3 \rightarrow \text{NaO} + \text{O}_2$ $\rightarrow \text{NaO}_2 + \text{O}$	208–377	1.0×10^{-9}	95	7.3×10^{-10} $< 4.0 \times 10^{-11}$	1.20	50	J 1
$\text{Na} + \text{OH} \xrightarrow{\text{M}} \text{NaOH}$		(See Table 2-1)					
$\text{Na} + \text{N}_2\text{O} \rightarrow \text{NaO} + \text{N}_2$	240–850	2.8×10^{-10}	1600	1.3×10^{-12}	1.20	400	J 2
$\text{Na} + \text{Cl}_2 \rightarrow \text{NaCl} + \text{Cl}$	294	7.3×10^{-10}	0	7.3×10^{-10}	1.30	200	J 3
$\text{NaO} + \text{O} \rightarrow \text{Na} + \text{O}_2$	290–573	4.4×10^{-10}	0	4.4×10^{-10}	1.50	200	J 4
$\text{NaO} + \text{O}_2 \xrightarrow{\text{M}} \text{NaO}_3$		(See Table 2-1)					
$\text{NaO} + \text{O}_3 \rightarrow \text{NaO}_2 + \text{O}_2$ $\rightarrow \text{Na} + 2\text{O}_2$	207–377 296	1.1×10^{-9} 6.0×10^{-11}	570 0	1.6×10^{-10} 6.0×10^{-11}	1.50 3.00	300 0	J 5
$\text{NaO} + \text{H}_2 \rightarrow \text{NaOH} + \text{H}$	266–310	(See Note)					J 6
$\text{NaO} + \text{H}_2\text{O} \rightarrow \text{NaOH} + \text{OH}$	260–716	5.06×10^{-10}	240	2.3×10^{-10}	1.50	200	J 7
$\text{NaO} + \text{NO} \rightarrow \text{Na} + \text{NO}_2$	296	1.5×10^{-10}	0	1.5×10^{-10}	4.00	0	J 8
$\text{NaO} + \text{CO} \rightarrow \text{Na} + \text{CO}_2$	294–300	1.6×10^{-10}	0	1.6×10^{-10}	1.50	100	J 9
$\text{NaO} + \text{CO}_2 \xrightarrow{\text{M}} \text{NaCO}_3$		(See Table 2-1)					
$\text{NaO} + \text{HCl} \rightarrow \text{products}$	308	2.8×10^{-10}	0	2.8×10^{-10}	3.00	0	J10
$\text{NaO}_2 + \text{O} \rightarrow \text{NaO} + \text{O}_2$	300	2.2×10^{-11}	0	2.2×10^{-11}	5.00	0	J11
$\text{NaO}_2 + \text{NO} \rightarrow \text{NaO} + \text{NO}_2$	296			$< 10^{-14}$			J12
$\text{NaO}_2 + \text{HCl} \rightarrow \text{products}$	295	2.3×10^{-10}	0	2.3×10^{-10}	3.00	0	J13
$\text{NaOH} + \text{H} \rightarrow \text{Na} + \text{H}_2\text{O}$	230–298	3.8×10^{-11}	0	3.8×10^{-11}	1.50	200	J14
$\text{NaOH} + \text{CO}_2 \xrightarrow{\text{M}} \text{NaHCO}_3$		(See Table 2-1)					
$\text{NaOH} + \text{HCl} \rightarrow \text{NaCl} + \text{H}_2\text{O}$	308	2.8×10^{-10}	0	2.8×10^{-10}	3.00	0	J15
$\text{NaHCO}_3 + \text{H} \rightarrow \text{Na} + \text{H}_2\text{O} + \text{CO}_2$	227–307	1.4×10^{-11}	1000	5×10^{-13}	2.00	0	J16
$\text{Hg} + \text{Br} \xrightarrow{\text{M}} \text{HgBr}$		(See Table 2-1)					
$\text{HgBr} + \text{NO}_2 \xrightarrow{\text{M}} \text{syn-BrHgONO}$		(See Table 2-1)					

HgBr + HO ₂ $\xrightarrow{\text{M}}$ BrHgOOH		(See Table 2-1)					
---	--	-----------------	--	--	--	--	--

Shaded areas indicate changes or additions since JPL19-5. Italicized entries in **blue** denote estimates.

^a Temperature range of available experimental data. This is not necessarily the range of temperature over which the recommended Arrhenius parameters are applicable. See the corresponding note for such information.

^b Units are cm³ molecule⁻¹ s⁻¹.

^c $f(298\text{ K})$ is the uncertainty factor at 298 K. To calculate the uncertainty at other temperatures, use the expression:

$$f(T) = f(298\text{ K}) \exp \left| g \left(\frac{1}{T} - \frac{1}{298} \right) \right|, \text{ note that the exponent is an absolute value.}$$

1.15.2 Notes: Metal Reactions

J1. Na + O₃. The recommendation is based on the measurements of Ager et al.,¹ Worsnop et al.⁶ as corrected in Worsnop et al.,⁷ and Plane et al.³ The data of Worsnop et al. supersede earlier work from that laboratory (Silver and Kolb⁵). Measurements made by Husain et al.² at 500 K are somewhat lower, probably because they did not recognize that secondary chemistry, NaO + O₃ → Na + 2O₂, interferes with the rate coefficient measurement. The temperature dependence is from the results of Worsnop et al.⁷ (214–294 K) and Plane et al.³ (208–377 K). Ager et al.¹ estimated that the NaO₂ + O product channel is ≤5%. Evidence that the NaO product is in the ²Σ⁺ excited electronic state was reported by Shi et al.⁴ and Wright et al.⁸ (Table: 94-26, Note: 94-26, Evaluated: 94-26) [Back to Table](#)

J2. Na + N₂O. The recommendation incorporates the data of Husain and Marshall,⁴ Ager et al.,¹ Plane and Rajasekhar,⁵ and Worsnop et al.⁷ Silver and Kolb⁶ measured a rate coefficient at 295 K that is lower and is superseded by Worsnop et al. Helmer and Plane³ report a measurement at 300 K in excellent agreement with the recommendation. Subsequently, Gómez Martin et al.² measured the rate constant for the Na + N₂O reaction at 295, 300, and 320 K; these near room temperature results are also in “excellent agreement” with the recommended 298 K value. Earlier, less direct studies were discussed by Ager et al.¹ The NaO product does not react significantly with N₂O at room temperature [*k*(for Na + N₂ + O₂ products) ≤ 10⁻¹⁶ cm³ molecule⁻¹ s⁻¹ and *k*(for NaO₂ + N₂ products) ≤ 2 × 10⁻¹⁵ cm³ molecule⁻¹ s⁻¹ (Ager et al.)]. Wright et al.⁸ used UV photoelectron spectroscopy to determine the product NaO is formed predominantly in the excited ²Σ⁺ state. (Table: 92-20, Note: 19-5, Evaluated: 19-5) [Back to Table](#)

- J3. Na + Cl₂.** Two room temperature measurements of the rate coefficient for this reaction are in excellent agreement: Silver¹ and Talcott et al.² The recommended value is the average of these results. (Table 87-41, Note: 87-41, Evaluated: 87-41) [Back to Table](#)
- (1) Silver, J. A. Room temperature rate constant for the reaction of Na with Cl₂. *J. Chem. Phys.* **1986**, *84*, 4718-4720, doi:10.1063/1.450003.

- J4. NaO + O.** The recommendation is based on measurements by Plane and Husain³ and Griffin et al.¹ The Na + O₃ reaction produces NaO predominately in the low lying A ²Σ⁺ state, which can radiatively and collisionally decay slowly to the X ²Π ground state. The Plane and Husain³ experiment was configured so that the predominant reactant was NaO X ²Π while the Griffin et al.¹ experiment was designed to maximize NaO A ²Σ⁺ concentrations. While the two states may not have identical reaction rate constants, their energy difference is small compared to reaction exothermicity and both states show reaction rate constants near the collisional limit. Since this reaction in the atmosphere will probably proceed through a mixture of the two lowest NaO electronic states and data are available at only one temperature for each state, the recommended rate constant is an average of the two measurements. Plane and Husain³ reported that ~0.01 of the Na product is in the 3²P excited state, while Griffin et al.¹ report a Na 3²P product branching ratio of 0.14 ± 0.04. This difference is consistent with the orbital correlation predictions of products for reaction of each NaO state as presented by Herschbach et al.² (Table: 06-2, Note: 06-2, Evaluated: 06-2) [Back to Table](#)
- (1) Griffin, J.; Worsnop, D. R.; Brown, R. C.; Kolb, C. E.; Herschbach, D. R. Chemical kinetics of the NaO (A²Σ⁺) + O(³P) reaction. *J. Phys. Chem. A* **2001**, *105*, 1643-1648, doi:10.1021/jp002641m.

- (3) Plane, J. M. C.; Husain, D. Determination of the absolute rate constant for the reaction O + NaO → Na + O₂ by time-resolved atomic chemiluminescence at λ = 589 nm [Na(3 ²P₁) → Na(3 ²S_{1/2}) + hv]. *J. Chem. Soc. Faraday Trans. 2* **1986**, *82*, 2047-2052, doi:10.1039/f29868202047.
- J5. NaO + O₃.** This reaction was studied by Silver and Kolb,³ Ager et al.,¹ and Plane et al.,² who agree on the rate coefficient and branching ratio. This agreement may be fortuitous because Silver and Kolb used an indirect method and an analysis based on their rate coefficient for the Na + O₃ reaction, which is about 1/2 of the recommended value. Ager et al. employed a somewhat more direct measurement, but the study is complicated by a chain reaction mechanism in the Na/O₃ system. Plane et al. reported rate coefficient measurements for the NaO₂ + O₂ product channel over the temperature range 207–377 K using pulsed photolysis LIF methods. The recommendation for that channel is based on all three studies, and the recommendation for the Na + 2O₂ channel is based upon the results of Silver and Kolb and Ager et al. The latter reaction channel may also have a significant temperature dependence. (Table: 25-1, Note: 94-26, Evaluated: 25-1) [Back to Table](#)
- (1) Ager, J. W., III; Talcott, C. L.; Howard, C. J. Gas phase kinetics of the reactions of Na and NaO with O₃ and N₂O. *J. Chem. Phys.* **1986**, *85*, 5584-5592, doi:10.1063/1.451573.
- (2) Plane, J. M. C.; Nien, C.-F.; Allen, M. R.; Helmer, M. A kinetic investigation of the reactions Na + O₃ and NaO + O₃ over the temperature range 207-377 K. *J. Phys. Chem.* **1993**, *97*, 4459-4467, doi:10.1021/j100119a033.

- J6. NaO + H₂.** The prior recommendation was based on two 297 K and one 294 K measurements by Ager and Howard¹ who reported the NaOH + H product channel rate constant. They also reported evidence of a Na + H₂O product channel and that a small fraction of the Na from this channel is in the 3²P excited state. Using direct mass spectral measurements of both NaO depletion and NaOH production in their flow reactor Gómez

Martin et al.² demonstrated that the Na + H₂O product channel is minor with a branching ratio estimate of (1.02 ± 0.14)%. They reported NaO + H₂ → NaOH + H rate constant measurements at 266 and 310 K that are ~5 times lower than Ager and Howard's three earlier measurements at 297, 297, and 294 K. Ager and Howard reported an averaged room temperature rate constant of (2.6 ± 1.0) × 10⁻¹¹ cm³ molecule⁻¹ s⁻¹ compared to (4.9 ± 1.2) × 10⁻¹² cm³ molecule⁻¹ s⁻¹ at 310 K and (6.0 ± 3.0) × 10⁻¹² cm³ molecule⁻¹ s⁻¹ at 266 K reported by Gómez Martin et al. Gómez Martin et al. discuss possible reasons for the large discrepancy, but do not identify definitive problems with either group's experiments. Because of the large unexplained discrepancy between the Ager and Howard and Gómez Martin et al. studies, no recommendation is given for this reaction.

(Table 19-5, Note: 19-5, Evaluated: 19-5) [Back to Table](#)

- (1) Ager, J. W., III; Howard, C. J. Gas phase kinetics of the reactions of NaO with H₂, D₂, H₂O, and D₂O. *J. Chem. Phys.* **1987**, *87*, 921-925, doi:10.1063/1.453726.
- (2) Gómez Martin, J. C.; Garraway, S. A.; Plane, J. M. C. Reaction kinetics of meteoric sodium reservoirs in the upper atmosphere. *J. Phys. Chem. A* **2016**, *120*, 1330-1346, doi:10.1021/acs.jpca.5b00622.

J7. NaO + H₂O. The prior recommendation was based on a room temperature (298 ± 1 K) measurement of (2.2 ± 0.4) × 10⁻¹⁰ cm³ molecule⁻¹ s⁻¹ by Ager and Howard¹ and a temperature dependent measurement by Cox and Plane² with the more extensive temperature dependent data favored. Cox and Plane's near room temperature (310 K) rate constants are (9.8 ± 2.4) and (9.3 ± 1.0) × 10⁻¹¹ cm³ molecule⁻¹ s⁻¹. While Gómez Martin et al.³ reported a 310 K rate constant value of (2.4 ± 0.6) × 10⁻¹⁰ cm³ molecule⁻¹ s⁻¹; in excellent agreement with Ager and Howard¹ and poor agreement with Cox and Plane.² Gómez Martin et al. discuss potential reasons for the discrepancy with the earlier measurement and conclude their latter result is more likely to be correct. After reviewing the results of all three studies, they recommend a near room temperature value of $k(300\text{--}310\text{ K}) = (2.3 \pm 0.5) \times 10^{-10} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ and an Arrhenius temperature dependence determined by a 2 kJ activation energy: $k(260\text{--}716\text{ K}) = 5.06 \times 10^{-10} \exp(-240/T) \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$; which is adopted here.

(Table: 19-5, Note: 19-5, Evaluated: 19-5) [Back to Table](#)

- (1) Ager, J. W., III; Howard, C. J. Gas phase kinetics of the reactions of NaO with H₂, D₂, H₂O, and D₂O. *J. Chem. Phys.* **1987**, *87*, 921-925, doi:10.1063/1.453726.
- (2) Cox, R. M.; Plane, J. M. C. An experimental and theoretical study of the reactions NaO + H₂O(D₂O) → NaOH(D) + OH(OD). *Phys. Chem, Chem. Phys.* **1999**, *1*, 4713-4720, doi:10.1039/A905601G.

J8. NaO + NO. The recommendation is based on an indirect measurement reported by Ager et al.¹

(Table 25-1, Note: 87-41, Evaluated: 25-1) [Back to Table](#)

- (1) Ager, J. W., III; Talcott, C. L.; Howard, C. J. Gas phase kinetics of the reactions of Na and NaO with O₃ and N₂O. *J. Chem. Phys.* **1986**, *85*, 5584-5592, doi:10.1063/1.451573.

J9. NaO + CO. Two flow reactor studies have published room temperature rate constant measurements. Kolb et al.² reported $k(294\text{ K}) = (2.1 \pm 0.5) \times 10^{-10} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ and 26 years later Gómez Martin et al.¹ reported $k(300\text{ K}) = (1.2 \pm 0.4) \times 10^{-10} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$. These results overlap within their estimated errors. An averaged rate constant of $k(294\text{--}300\text{ K}) = (1.6 \pm 0.5) \times 10^{-10} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ is recommended.

Table 2-1 Rate Constants for Termolecular Reactions.....	2-5
Table 2-2 Rate Constants for Chemical Activation Reactions.....	2-55

2.1 Introduction

Recombination rate constants for simple association reactions of the type $A + B \leftrightarrow [AB]^* \xrightarrow{M} AB$ (where the asterisk denotes rovibrational excitation) are pressure dependent. The low-pressure-limiting rate constants are given in the form:

$$k_0(T) = k_0^{298} \left(\frac{298}{T} \right)^n \text{ cm}^6 \text{ molecule}^{-2} \text{ s}^{-1}, \quad (2.1)$$

(where k_0^{298} has been adjusted for air as the third body). The limiting high-pressure rate constant is given in a similar form:

$$k_\infty(T) = k_\infty^{298} \left(\frac{298}{T} \right)^m \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}. \quad (2.2)$$

To obtain the effective second-order rate constant for a given condition of temperature and pressure (altitude), the following formula is used:

$$k_f(T, [M]) = \left\{ \frac{k_\infty(T)k_0(T)[M]}{k_\infty(T) + k_0(T)[M]} \right\} 0.6 \left\{ 1 + \left[\log_{10} \left(\frac{k_0(T)[M]}{k_\infty(T)} \right) \right]^2 \right\}^{-1} \quad (2.3)$$

where $[M]$ is the total gas concentration. The fixed value 0.6 that appears in this formula fits the data for all listed reactions adequately, although in principle this quantity is temperature-dependent and may be different for each reaction. However, there are rarely sufficient data to accommodate additional parameters. The four parameters, $k_0(298 \text{ K})$, n , $k_\infty(298 \text{ K})$, and m are given in Table 2.1 for simple association reactions.

Some association reactions produce not only the recombination product, but additional products that appear to originate from a simple bimolecular reaction. For example, the reaction between OH and CO produces not only HOCO, the recombination product, but also H and CO₂, which resemble the products of a simple metathesis reaction. This is an example of a **chemical activation reaction**, which takes place on a potential energy surface that includes HOCO*, the rovibrationally excited free radical intermediate. The reactions involving this intermediate can be described with the following reaction scheme:

The net loss of reactants is thus the sum of two pressure-dependent processes, an association to yield HOCO and the chemical activation process yielding H and CO₂. In the limit of zero pressure (i.e., [M] = 0), the only products are H + CO₂. The yield of H + CO₂ is diminished and the yield of HOCO is increased as the pressure rises. In the limit of very high pressure, the only product is HOCO. The pressure-dependent rate constants are shown here in two common formats:

Figures: Two common formats showing the same chemical reaction rate constants as functions of pressure for a chemical activation system.

The chemical activation reaction scheme illustrated above is the basis for a model^{1,2,5} that describes the contributions from the two coupled processes:

- 1) Eq. 2.3 ($k_f(T, [M])$) for the association reaction (e.g. for producing HOCO). This is the same expression that is used for simple association reactions.
- 2) Eq. 2.4 $k_f^{CA}(T, [M])$ for the formation of the “chemical activation products” (e.g. for producing H + CO₂):

$$k_f^{CA}(T, [M]) = k_{int}(T) \left[1 - \frac{k_f(T, [M])}{k_{\infty}(T)} \right] \quad (2.4)$$

where $k_{int}(T)$ is the second order rate constant at [M] = 0 (i.e., the zero-pressure intercept) given by the Arrhenius expression in Eq. 2.5.

$$k_{int}(T) = A \exp(-B/T) \quad (2.5)$$

The total rate constant for loss of reactants is given by Eq. 2.6:

$$k_f^{total}(T, [M]) = k_f(T, [M]) + k_f^{CA}(T, [M]) \quad (2.6)$$

The six parameters, $k_o(298 \text{ K})$, n , $k_{\infty}(298 \text{ K})$, m , A , and B , are listed in Table 2.2 for chemical activation systems.

The discussion that follows outlines the general methods we have used in establishing this table, and the notes to the table discuss specific data sources. Recent advances in theory have allowed direct calculation of rate constants for some reactions using RRKM/Master Equation methods.

2.2 Low-Pressure-Limiting Rate Constant, $k_o^x(T)$

Troe⁴ has described a simple method for obtaining low-pressure-limiting rate constants. In essence this method depends on the definition:

$$k_o^x(T) \equiv \beta_x k_{o,sc}^x \quad (2.7)$$

Here sc signifies “strong” collisions, x denotes the bath gas, and β_x is an efficiency parameter ($0 < \beta_x < 1$), which provides a measure of energy transfer. The strong collision rate constant can be calculated with some accuracy from knowledge of molecular parameters available from experiment and more from theory.

The coefficient β_x is related to the average energy transferred in a collision with gas x , $\langle \Delta E \rangle_x$, via:

$$\frac{\beta_x}{(1 - \sqrt{\beta_x})} = \frac{\langle \Delta E \rangle_x}{F_E kT} \quad (2.8)$$

Notice that $\langle \Delta E \rangle$ is quite sensitive to β . F_E is the correction factor of the energy dependence of the density of states (a quantity of the order of 1.1 for most species of stratospheric interest).

For some of the reactions of possible stratospheric interest reviewed here, there exist data in the low-pressure limit (or very close thereto), and we have chosen to evaluate and unify this data by calculating $k_o^x(T)$ for the appropriate bath gas x and computing the value of β_x corresponding to the experimental value.⁴ A compilation³ gives details for many of the reactions considered here.

From the β_x values (most of which are for N_2 , i.e., β_{N_2}), we compute $\langle \Delta E \rangle_x$ according to the above equation. Values of $\langle \Delta E \rangle_{N_2}$ of approximately 0.3–1 kcal mole⁻¹ are generally expected. If multiple data exist, we average the values of $\langle \Delta E \rangle_{N_2}$ and recommend a rate constant corresponding to the β_{N_2} computed in the equation above.

Master equation calculations allow direct calculation of low-pressure rate constants and of β_x .

Where no data exist, we have sometimes estimated the low-pressure rate constant by taking $\beta_{N_2} = 0.3$ at $T = 298$ K, a value based on those cases where data exist.

2.3 Temperature Dependence of Low-Pressure Limiting Rate Constants: $(298/T)^n$

The value of n recommended here comes from measurements or, in some cases, a calculation of $\langle \Delta E \rangle_{N_2}$ from the data at 298 K, and a computation of $\beta_{N_2}(200 \text{ K})$ assuming that $\langle \Delta E \rangle_{N_2}$ is independent of temperature in this range. This $\beta_{N_2}(200 \text{ K})$ value is combined with the computed value of $k_{o,sc}(200 \text{ K})$ to give the expected value of the actual rate constant at 200 K. This latter, in combination with the value at 298 K, yields the value of n .

This procedure can be directly compared with measured values of $k_o(200 \text{ K})$ when those exist. Unfortunately, very few values at 200 K are available. There are often temperature-dependent studies, but some ambiguity exists when one attempts to extrapolate these down to 200 K. If data are to be extrapolated beyond the measured temperature range, a choice must be made as to the functional form of the temperature dependence.

There are two general ways of expressing the temperature dependence of rate constants. Either the Arrhenius expression:

$$k_o(T) = A \exp(-E/RT) \quad (2.9)$$

or the form:

$$k_o(T) = A' T^{-n} \quad (2.10)$$

is employed. Neither of these extrapolation techniques is soundly based, and since they often yield values that differ substantially, we have used the power law expression above as the basis of our recommendations.

2.4 High-Pressure-Limit Rate Constants, $k_\infty(T)$

High-pressure rate constants can often be obtained experimentally, but those for the relatively small species of stratospheric importance usually reach the high-pressure limit at inaccessibly high pressures. This leaves two sources

of these numbers, the first being estimates based upon theory, and the second being extrapolation of fall-off data up to higher pressures.

Stratospheric conditions generally render reactions of interest much closer to the low-pressure limit and thus are fairly insensitive to the high-pressure value. This means that while the extrapolation is long, and the value of $k_{\infty}(T)$ is often not very accurate, a “reasonable guess” of $k_{\infty}(T)$ will then suffice. In a few cases, we have declined to guess since the low-pressure limit is effective over the entire range of stratospheric conditions.

2.5 Temperature Dependence of High-Pressure-Limiting Rate Constants: $(298/T)^m$

Commonly, there are very few data upon which to base a recommendation for values of m . Values in Tables 2.1 and 2.2 are often estimated, based on models for the transition state of bond-association reactions and whatever data are available. In general, the temperature dependence of these rate constants is expected to be small.

2.6 Uncertainty Estimates

For three-body reactions (Tables 2.1 and 2.2) uncertainties are assigned using a procedure that is analogous to that employed for bimolecular reactions in Table 1-1. Values of $f(298\text{ K})$ are given for these rate constants at room temperature and assumed to be valid at all pressures. The additional uncertainty arising from the temperature extrapolation is expressed with a g -factor as in Table 1-1. Given that uncertainties for an expression with four parameters are expressed with only two parameters, a certain amount of arbitrariness is involved in their choice.

Shaded areas indicate changes or additions since JPL19-5.

The values quoted are suitable for air as the third body, M.

^a Units are $\text{cm}^6 \text{ molecule}^{-2} \text{ s}^{-1}$.

^b Units are $\text{cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$.

$f(298 \text{ K})$ is the uncertainty factor at 298 K. To calculate the uncertainty at other temperatures, use the expression:

$$f(T) = f(298) \exp \left| g \left(\frac{1}{T} - \frac{1}{298} \right) \right|$$

Note that the exponent is an absolute value

2.7 Notes for Table 2-1: Termolecular Reactions

- A1. **O + O₂.** Low pressure limit and T dependence are an average of Klais et al.,¹⁰ Huie et al.,⁷ and Lin and Leu.¹¹ These studies in N₂ and Ar are in the temperature range 200 < T/K < 268. The result is in agreement with the study of Hippler et al.⁶ and the extrapolated recommendation fits their lower pressure N₂ data down to 100 K. High pressure studies by Croce de Cobos and Troe² are in agreement with this recommendation. Rawlins et al.¹⁴ estimate values in Ar between 80 and 150 K from nascent vibrational distributions that are a factor of two higher than the recommendation extrapolated to 80 K. The temperature dependence of the rate constant determined from the experimental data are in excellent agreement with the value of n = 2.36 determined from the calculations of Patrick and Golden.¹³ However there is some reason to believe that a radical-complex plays a role in this process.^{6,8,12,19} Kaye⁹ has calculated isotope effects for this reaction, using methods similar to those discussed in the Introduction of this document (see Troe¹⁷ and Patrick and Golden¹³). Isotope effects have been reported by Anderson et al.¹ and Gross and Billing.⁴ Measurements of isotopic fractionation by Mauersberger and colleagues¹⁸ and Thiemens and co-workers¹⁵ reveal distinctly non-statistical effects. Various attempts at theoretical explanations exist,⁵ but the detailed knowledge of the potential energy surface required is unavailable. A summary of theoretical and experimental studies by Schinke et al.¹⁶ goes into great detail on this subject as does a study by Gao and Marcus.³

A2. O(¹D) + N₂. Recommended parameters (including *f* and *g*) are from Estupiñán et al.¹ whose detection capabilities were more advanced than those employed in earlier studies. Kajimoto and Cvetanovic³ report a value at 296 K of $6.5 \times 10^{-37} \text{ cm}^6 \text{ s}^{-1}$. Maric and Burrows⁴ extract $(8.8 \pm 3.3) \times 10^{-37} \text{ cm}^6 \text{ s}^{-1}$ from a study of the photolysis of synthetic air. Gaedtke et al.² report an approximate value of 10^{12} in molar units, which translates to 2.8×10^{-36} in molecular units. The rate constant is extremely low in this special system due to electronic curve crossing.

B1. H + O₂. Studies by Kurylo,⁸ Wong and Davis,¹³ Hsu et al.,⁷ Hsu et al.,⁶ Cobos et al.,⁴ Pirraglia et al.,¹⁰ Carleton et al.,³ Troe,¹² Bates et al.,¹ Michael et al.,⁹ and Fernandes et al.⁵ have been considered. All are in good agreement. A theoretical study by Sellevåg et al.¹¹ contributes to knowledge of the reaction. The experimental/theoretical study by Fernandes et al.⁵ provides an estimate of the high pressure limit, which is adopted in this recommendation. Because only a few measurements have been reported at low temperatures in the atmospheric range, data from a wider range of conditions were considered. Thus, the recommendation for the low-pressure limit is based on a least-squares analysis (using the adopted high-pressure limit) of all of the data from the studies listed above with $T \leq 500 \text{ K}$ and N₂ concentration $< 10^{20} \text{ molecules cm}^3$. The estimated error limits were chosen so that all of the data used for the recommendation fall within the 2σ error bounds. Two studies^{1,9} have pointed out the large effect of water vapor as the collider gas. Baulch et al.² have evaluated this reaction over the temperature range $298 < T/\text{K} < 1500$.

B2. OH + OH. Recommended values are from fits of measurements by Zellner et al.⁶ in N_2 , by Forster et al.² and Fulle et al.³ in 1–150 bar He scaled to N_2 . A study by Fagerstrom et al.¹ in 85–1000 mbar SF_6 gives slightly different values. A pressure independent bimolecular channel to $\text{H}_2\text{O} + \text{O}$ with a rate 1.8×10^{-12} is observed (see Table 1-1). Zellner et al. used somewhat different values for this rate constant to make substantial corrections to their measured values. Changing to the accepted value will make large changes in the Zellner et al. values and it is unclear how to evaluate this. Trainor and von Rosenberg⁵ report a value at 300 K that is lower than recommended by a factor of 2.7. A theoretical study by Sellevåg et al.⁴ recommends values for He that are compatible with the recommendation.

C2. OH + NO. The low pressure limit rate constant has been reported by Anderson and Kaufman,² Stuhl and Niki,¹⁷ Morley and Smith,¹³ Westenberg and de Haas,¹⁸ Anderson et al.,³ Howard and Evenson,¹² Harris and Wayne,¹¹ Atkinson et al.,⁶ Overend et al.,¹⁴ Anastasi and Smith,¹ Burrows et al.,⁷ and Atkinson and Smith.⁴ The general agreement is good, and the recommended values of both the rate constant and the temperature dependence are weighted averages. Studies by Sharkey et al.¹⁶ and Donahue et al.⁸ in the transition regime between low and high pressure limits are in agreement and serve to reduce the uncertainty. These latter studies yield a value for the high pressure limiting rate constant in agreement with the results of Forster et al.,⁹ whose study reached pressures of 100 bar in He. The temperature dependence of the high pressure limiting rate constant is from the data of Anastasi and Smith¹ and Sharkey et al. (both *cis*- and *trans*-HONO are expected to be formed.) Fulle et al.¹⁰ report a high pressure limit in agreement with Forster et al.⁹ Pagsberg et al.¹⁵ report low pressure values in SF₆ that are compatible (i.e., the ratio of collision efficiencies is about a factor of two) with the recommendation. A study by Zabarnick¹⁹ is noted. The error limits encompass the differences with the IUPAC⁵ recommendation.

C3. OH + NO₂. This reaction has been the subject of detailed study. There are two product channels, one to HONO₂ (nitric acid) and the other to HOONO (pernitrous acid). (There are at least two conformers of HOONO, *cis-cis* and *trans-perp*, which are thought to be equilibrated under atmospheric conditions.) Golden and Smith¹⁴ concluded that there were two pathways and they offered parameters in the format of this recommendation that were given in the note in JPL 02-25.²⁰ Experiments by Hippler and co-workers^{11,12} up to about 100 bar at 300 K and the finding of a double exponential decay of OH at 430 K and 100 bar implicate a second pathway.¹⁵ Nizkorodov and Wennberg¹⁸ report 5% HOONO at 253 K and 20 Torr of an N_2/He buffer gas. Bean et al.³ and Pollack et al.¹⁹ report on the spectroscopy of the HOONO conformer. Mollner et al.¹⁷ report the total rate constant at 298 K in N_2 , O_2 and air from 50 to 900 Torr, and the branching ratio for the two pathways at 298 K in a mixture of N_2 and H_2 from 20 to 760 Torr. They find the efficiency of air to be 94% that of N_2 and by simultaneously fitting both the branching ratio and the total rate constant they obtained parameters at 298 K: $k_0 = 1.51 \times 10^{-30}$ and $k_\infty = 1.84 \times 10^{-30}$ for the HONO₂ pathway and $k_0 = 6.2 \times 10^{-32}$ and $k_\infty = 8.1 \times 10^{-11}$ for the HOONO pathway.

Golden et al.¹³ have performed RRKM/master-equation calculations on an ab initio potential energy, which are the basis for the previous recommendation, which is retained for the current recommendation. Golden et al.¹³ adjusted their calculations to agree with experiments: the low pressure limit and the high pressure limiting rate constants and their temperature dependences are from a fit to the data of Hippler et al.,¹⁵ Anastasi and Smith,¹ Wine et al.,²¹ Donahue et al.,⁸ Dransfield et al.,⁹ Brown et al.,⁴ and D'Ottone et al.⁷ Brown et al. report that O_2 is about 30% less efficient than N_2 as a collider and suggest that air might therefore have a total efficiency of 0.94 relative to N_2 . The total rate constants reported by Mollner et al.¹⁷ are in excellent agreement with the recommendation. Data from Anderson et al.,² Howard and Evenson,¹⁶ Burrows et al.,⁶ and Erler et al.¹⁰ are in essential agreement. Data of Forster et al.¹¹ and Fulle et al.¹² are acknowledged to be about 30% too high.¹⁵ Burkholder et al.⁵ and Dransfield et al.⁹ searched for the isomer HOONO, but were unable to detect it. The description of the reaction between HO and NO_2 , as consisting of two product channels, requires that the data represent the sum of the two pathways. The branching ratios measured at 298 K by Mollner et al.¹⁷ are about 25% lower than from the recommendation; Mollner et al. did not report branching ratios at other temperatures. The fate of HOONO has to be included in atmospheric models. If this fate involves rapid loss due to reaction or photolysis, the effect of the second pathway is the diminution of the HONO₂ forming rate constant. Evaluation of data, taking into account both pathways, indicates that the contribution of the HOONO forming reaction can be from 5 to 15% under atmospheric conditions at 298 K. The equilibrium constant is given in Table 3-1.

C4. HO₂ + NO. Butkovskaya et al. studied this reaction in a high-pressure turbulent flow reactor coupled to a chemical ionization mass spectrometer.^{2,4} Very small yields (<1%) of nitric acid were measured from 223 to 323 K and from 72 to 600 Torr of (mostly) N₂ and in the absence of water vapor. The yields were enhanced by the presence of water vapor.^{3,4} In systems not including water vapor, they summarized the yield of nitric acid relative to the yield of NO₂ (from $\text{HO}_2 + \text{NO} \rightarrow \text{OH} + \text{NO}_2$) as follows:

$$\beta(T, P) = (530 \pm 10) / T(K) + (6.4 \pm 1.3) \times 10^{-4} P(\text{Torr}) - (1.73 \pm 0.07).$$

At low temperatures, β extrapolated below 100 Torr has a large non-zero intercept at zero pressure,^{2,4} which is not expected for a gas phase reaction. In the presence of water vapor, the chemical ionization mass spectrometer signals are affected significantly³ and the yield of nitric acid increases linearly with added water vapor,^{3,4} reaching an enhancement factor of ~8 at $[\text{H}_2\text{O}] = 4 \times 10^{17} \text{ molecule cm}^{-3}$ and 298 K³:

$$f_{\text{H}_2\text{O}} \approx (1 + 2 \times 10^{-17} [\text{H}_2\text{O}])$$

where the concentration of H₂O is expressed in molecules cm⁻³. If this effect is due to reaction of the hydrated HO₂ complex (i.e. $\text{HO}_2 \cdot \text{H}_2\text{O} + \text{NO} \rightarrow \text{HNO}_3 + \text{H}_2\text{O}$), then the rate constant of the complex with NO is $\sim 6 \times 10^{-13} \text{ cm}^3 \text{ s}^{-1}$ at 298 K in the presence of 200 Torr of N₂.³

Ab initio electronic structure calculations support the possibility of gas phase HONO₂ formation, but satisfactory simulations using master equations have been elusive.^{1,5-7} The measured yields show a surprising

intercept at zero pressure, which might be indicative of wall reactions. However, Butkovskaya et al. have made great efforts to minimize wall reactions, and their analysis suggests that wall reactions should not be important.^{3,4} Until the results have been confirmed by other groups and are better understood, no recommendation can be made. These rate parameters are provided for the purposes of model evaluation only and do not constitute a recommendation by the Panel.

C5. HO₂ + NO₂. Christensen et al.² report rate constants 219 < T/K < 298 and 45 < P/Torr < 200. They show that methanol, present in most other studies confounds the results by forming bound complexes with HO₂. They also suggest that some measurements yielded low rate constants as a result of perturbations to the NO₂/N₂O₄ equilibrium. Sander et al.⁸ also noted that H₂O vapor enhances the reaction rate significantly. Bacak et al.¹ reported data obtained using CIMS, which is more sensitive and less prone to interference than UV and IR absorbance. They used initial radical concentrations 1000 times lower than previous work, eliminating potential interference from the HO₂ + HO₂ reaction. Rate constants measured by Bacak et al.¹ at 200 K, 223 K, and 298 K are quite similar to each other, suggesting very little temperature dependence (i.e., Bacak gives $n = 0.2$ and $m = 0.5$), which differs from previous work, leading them to conclude that previous work was affected by the HO₂ + HO₂ reaction at T < 277 K. At ~298 K, rate constants measured by Sander et al.,⁸ Kurylo et al.,^{6,7} Christensen et al., and Bacak et al. are in excellent agreement, suggesting that at 298 K these studies were not affected by interferences. The recommendation is based on the data at T ≥ 277 K from Sander and Peterson,⁸ Kurylo and Ouellette,^{6,7} Christensen et al.,² and the data at 298 K of Bacak et al. The recommended parameters are similar to the previous recommendation; the exponent for k_{∞} is small, as expected for a recombination reaction. The low-T data of Bacak et al. fall about a factor of two lower than the fit. Although CIMS experiments have the highest sensitivity and avoid spectral interference, the data are limited to only three temperatures and they have not been replicated at the lowest two temperatures. The error parameter g was chosen so that the CIMS data at low T fall within the error range. Other studies by Howard,⁵ Simonaitis and Hecklen,⁹ and Cox and Patrick⁴ are in reasonable agreement with the recommendation, as is the value of Christensen et al.³

C6. $\text{NO}_2 + \text{NO}_3$. The recommended limiting rate constants at 298 K (N_2 bath gas) and temperature exponents are the geometric mean of the corresponding rate constants and the average of the exponents, respectively, obtained by nonlinear least squares. The low pressure limit is based on the data of Kircher et al.,⁹ Smith et al.,¹² Wallington et al.,¹⁴ Orlando et al.,¹¹ and Nakano et al.,¹⁰ combined with $k_{\text{uni}} \times K_{\text{eq}}$ data (recommended K_{eq} from Table 3-1); k_{uni} data were taken from Connell et al.³ and Cantrell et al.² The high pressure limit is based on data from Kircher et al.,⁹ Smith et al.,¹² Wallington et al.,¹⁴ Hahn et al.,⁶ and $k_{\text{uni}} \times K_{\text{eq}}$ (K_{eq} from Table 3-1); k_{uni} data were taken from Cantrell et al.² and Ide et al.⁷ The recommendation is in good agreement with the data of Burrows et al.¹ and with k_{uni} (multiplied by K_{eq} from Table 3-1) reported by Viggiano et al.¹³ Values from Croce de Cobos et al.⁴ were excluded due to arguments given by Orlando et al.,¹¹ who point out that a reanalysis of these data using better values for the rate constant for $\text{NO}_3 + \text{NO} \rightarrow 2\text{NO}_2$ yields a negative value for $\text{NO}_2 + \text{NO}_3 + \text{M}$. The study of Fowles et al.⁵ is noted, but not used. Johnston et al.⁸ reviewed this reaction. The rate constant for the reverse reaction (k_{uni}) can be obtained as the ratio of the recommended recombination rate constant k_{rec} from this table, divided by the recommended K_{eq} from Table 3-1: $k_{\text{uni}} = k_{\text{rec}}/K_{\text{eq}}$.

C7. $\text{NO}_3 + \text{M}$. Johnston et al.³ and Davidson et al.¹ have suggested significant thermal decomposition of NO_3 . This has been disputed by Russell et al.⁴ Davis et al.² claim that the barrier to thermal dissociation is 47.3 kcal mol⁻¹. This would seem to rule out such a process in the atmosphere.

D1. $\text{CH}_3 + \text{O}_2$. Data from Kaiser⁵ are fit to the NASA format. The ranges of this study were $3 < P/\text{Torr} < 11000$ and $264 < T/\text{K} < 370$. The rate constant was measured relative to the reaction $\text{CH}_3 + \text{Cl}_2 \rightarrow \text{CH}_3\text{Cl} + \text{Cl}$, $k/\text{cm}^3 \text{ molecule}^{-1} \text{ s}^{-1} = 1.61 \times 10^{-12} \exp(-530/RT)$. The recommended values are in good agreement with those from Selzer and Bayes.¹² These workers determined the rate constants as a function of pressure in N_2 , Ar , O_2 , and He . Plumb and Ryan¹⁰ report a value in He which is consistent within error limits with the work of Selzer and Bayes. Pilling and Smith⁹ have measured this process in Ar (32–490 Torr). Cobos et al.² have made measurements in Ar and N_2 from 0.25 to 150 atmospheres. They report parameters somewhat different than recommended here. The work of Laguna and Baughcum⁷ seems to be in the fall-off region. Results of Pratt and Wood¹¹ in Ar are consistent with this recommendation, although the measurements are indirect. The suggested value accommodates the values of Keiffer et al.,⁶ who measured the process in Ar between 20 and 600 Torr and in the range $334 < T/\text{K} < 582$. Data of van den Bergh and Callear,¹³ Hochanadel et al.,⁴ Basco et al.,¹ Washida and Bayes,¹⁵ Laufer and Bass,⁸ and Washida¹⁴ are also considered. A theoretical study by Zhu et al.¹⁶ is in reasonable agreement with the recommendation. A study by Fernandes et al.³ at pressures from 2–1000 bar and temperatures between 300 and 700 K presents a parameterization of the rate constant as a function of pressure and temperature which is in agreement with this recommendation at 300 K. If their parameters are used at 200 K the agreement is not as good, but is within the 95% uncertainty limit.

D2. OH + C₂H₂. The rate constant for this complex process has been examined by Smith et al.¹³ in the temperature range from 228 to 1400 K, and in the pressure range 1 to 760 Torr. Their analysis, which is cast in similar terms to those used here, is the source of the rate constants and temperature dependences at both limits. The negative value of *m* reflects the fact that their analysis includes a 1.2 kcal/mol barrier for the addition of OH to C₂H₂. The data analyzed include those of Pastrana and Carr,¹ Perry et al.,¹⁰ Michael et al.,⁸ and Perry and Williamson.¹¹ Other data of Wilson and Westenberg,¹⁶ Breen and Glass,³ Smith and Zellner,¹⁴ and Davis et al.⁴ were not included. Studies by Liu et al.⁷ and Lai et al.⁶ are in general agreement with the recommendation. Calculations of *k₀* via the methods of Patrick and Golden⁹ yield values compatible with those of Smith et al.¹³ A study by Sørensen et al.¹⁵ at 298 K and pressures from 25 to 8000 Torr of bath gas suggests *k₀*/cm⁶ molecule⁻² s⁻¹ = 2.92 × 10⁻³⁰, *k_∞*/cm³ molecule⁻¹ s⁻¹ = 9.69 × 10⁻¹³ and *F_c* = 0.6. No difference was found between air, N₂/O₂ mixtures or O₂ as the bath gas. These values yield rate constants as a function of pressure at 298 K in agreement with this recommendation, so the recommended values are unchanged from JPL 02-25. Earlier, Fulle et al.⁵ reported a high pressure limiting rate constant of 2 × 10⁻¹² cm³ molecule⁻¹ s⁻¹, which is the basis for the IUPAC² recommendation. A theoretical study by Senosiain et al.¹² is in essential agreement with this recommendation.

D3. OH + C₂H₄. The recommendation for the low pressure limit at 300 K is the average of fitted values from studies carried out over a significant range of pressure using synthetic air (Klein et al.⁹), N₂ (Vakhtin et al.¹⁷ and Cleary et al.²), or Argon (Klein et al.⁹). All three colliders were treated as equivalent. The recommended temperature exponent (*n*) was taken from the master equation analysis by Golden,⁶ who fitted the experimental rate constants in N₂, including those at very low temperatures (96, 110, and 165 K) reported by Vakhtin et al.¹⁷ The recommendation for the high pressure limit at 300 K is the average of fitted values from eight data sets measured near 300 K using helium (Tully et al.,¹⁶ Kuo and Lee,¹⁰ and Cleary et al.²), argon (Klein et al.⁹), N₂ (Vakhtin et al.¹⁷ and Cleary et al.²), and synthetic air (Klein et al.⁹). The recommended temperature exponent was from a least squares fit of the high pressure limiting values obtained from individual fits of data at 15 temperatures ranging from 200 K to 430 K, including data near 300 K.^{2,9,10,16,17} In addition to the studies already mentioned, the recommended high pressure rate constants are in good agreement with the data of Davis et al.,⁴ Howard,⁸ Greiner,⁷ Morris et al.,¹² and Overend and Paraskevopoulos¹³ in helium, Atkinson et al.¹ in argon, and Lloyd et al.¹¹ and Cox³ in nitrogen/oxygen mixtures. The parameters recommended are similar to the curve proposed by Klein et al.⁹ at 298 K. Kuo and Lee¹⁰ report a stronger temperature dependence for the low-pressure limit (*n*=4), but the present recommendation is in good agreement with their measured rate constants. Calculations of the type in Patrick and Golden¹⁴ as described in Vakhtin et al.¹⁷ yield *n* = 4.2, although they use a somewhat low value for energy transfer by nitrogen. The high-pressure limit temperature dependence has been determined by several workers. Zellner and Lorenz¹⁸ report a value equivalent to *m* = +0.8 over the range (296 < T/K < 524) at about 1 atmosphere. A value of *m* = +2.0 fits the data (540 < T/K < 670) of Diau and Lee.⁵ Cleary et al.² report values in N₂ at 295 K. They also report values in He between 200 and 400 K. They perform master equation calculations and report fitting parameters. Taylor et al.¹⁵ report data at a single pressure and 69 and 86 K. Their data are well-accommodated by this recommendation and by the parameters in Cleary et al.²

D4. $\text{OH} + \text{CH}_3\text{CH}=\text{CH}_2$ (propene). The following studies have been used to reach the recommendation: Spangenberg et al.¹⁰ in a Laval nozzle expansion of N_2 with LIF detection of OH at 293 K and at individual points from 114 to 58 K; Vakhtin et al.^{12,13} in a Laval nozzle expansion of N_2 with LIF detection of OH at 296 K and individual points at 96, 110, and 165 K; Nielsen et al.⁶ in a pulse radiolysis experiment (kinetic UV absorbance of OH radical) at 298 K in 1 atm of air; Wallington¹⁴ in a pulsed laser photolysis experiment with LIF detection of OH at 298 K in Argon; Schmidt et al.⁹ with laser photolysis and LIF of OH at 295 K in 1 atm of air; Tully and Goldsmith¹¹ with laser photolysis and LIF detection of OH at 293 to 467 K in 25 to 600 Torr of He; Zellner and Lorenz¹⁵ laser photolysis and resonance fluorescence detection of OH at 297 K in 1.3–130 mbar of Ar; Klein et al.⁴ with a relative rate measurement (relevant to n-Hexane) at 295 K in 1.3–1000 mbar of air; Atkinson and Aschmann¹ from relative rate measurements at 295 K in 1 atm of air; Nip and Paraskevopoulos⁷ with flash photolysis and resonance absorption at 297 K in 75 mbar of an $\text{H}_2/\text{N}_2\text{O}$ mixture; Ravishankara et al.⁸ with flash photolysis and resonance fluorescence of OH at 295 K in 20 and 200 Torr of He; and Atkinson and Pitts² by flash photolysis and resonance fluorescence of OH at 298–425 K in 25–100 Torr of Ar. Additional studies have been reviewed by Calvert et al.³ The recommended high pressure rate constant at 298 K is the geometric mean of all of the studies listed above, except for the relative rate measurement of Klein et al.⁴ The temperature exponent of k_∞ (parameter m) is the average of the values obtained from weighted least squares fits of data from Tully and Goldsmith¹¹ and from Vakhtin et al.,¹³ the former extends upward from ~300 K and the latter extends downward. Pressure fall-off is only apparent at lower pressures and higher temperatures; most studies did not observe significant fall-off. Usable fall-off data near 300 K are available from Klein et al.⁴ (Ar bath gas), Zellner and Lorenz¹⁵ (Ar bath gas), and Vakhtin et al.¹³ (N_2 bath gas). These fall-off data sets are for two different collider gases and provide only rough estimates of $k_0(298)$; the error factor associated with k_0 is at least $\times 3$. Because no temperature-dependent fall-off data are available, the recommendation for the temperature exponent (parameter n) is based on the estimate by Calvert et al.³ Loison et al.,⁵ using a fast flow reactor coupled to a time of flight mass spectrometer, found that $71 \pm 16\%$ of the reaction near room temperature proceeds by addition of the OH to the terminal CH_2 group. D5. OH + CH₂=C(CH₃)CH₃ (*iso*-butene). The rate constant is not dependent on pressure even at 1 Torr of helium, suggesting that it is very near the high-pressure limit in all of the reported studies. The recommended high pressure rate constant at 298 K is the geometric mean of the absolute rate constants reported by Atkinson and Pitts (flash photolysis (FP) with resonance fluorescence (RF) detection of OH)² and relative rate measurements reported by Wu et al.⁸ (cited by Calvert et al.⁴), Barnes et al.,³ Ohta,⁶ and Atkinson and Aschmann.¹ The recommendation is in fair agreement with the early discharge-flow measurement of Morris and Niki.⁵ The temperature dependence is based on the measurements of Atkinson and Pitts.² The estimated 2σ error limits are set to include all of the data used in the recommendation; because there is only one study of temperature dependence, *f*(298 K) and *g* were set to 1.2 and 200, respectively. Calvert et al.⁴ reviewed the data published prior to 2000 and recommended rate constants in reasonable agreement with the present recommendation. The reaction proceeds mostly (>90%) by addition of OH to the two carbon atoms at the ends of the double bond.⁴ Peeters et al.⁷ reported that $85 \pm 10\%$ of the addition is to the terminal carbon atom, producing a tertiary free radical (the balance produces a primary free radical).

D6. OH + CH₂=CH₂CH₂CH₃ (1-butene). The rate constant is not dependent on pressure even at 1 Torr of helium, suggesting that it is very near the high-pressure limit in all of the studies. The recommended high pressure rate constant at 298 K is the geometric mean of the absolute rate constants reported by Atkinson and Pitts² (flash photolysis (FP) with resonance fluorescence (RF) detection of OH), Ravishankara et al.¹³ (FP-RF), Nip and Paraskevopoulos⁹ (FP with resonance absorption (RA) detection of OH), Biermann and Pitts⁴ (discharge flow (DF) with mass spectrometry (MS) detection), Sims et al.¹⁴ (Laval-Nozzle flow apparatus (LN) and laser induced fluorescence (LIF) detection of OH), Vakhtin et al.¹⁵ (LN-LIF), and relative rate measurements reported by Wu et al.¹⁷ (cited by Calvert et al.⁵), Lloyd et al.,⁶ Winer et al.,¹⁶ Barnes et al.,³ Ohta,¹⁰ and Atkinson and Aschmann.¹ The recommendation is in good agreement with the early discharge-flow measurement of Morris and Niki,⁸ and in poor agreement with that of Pastrana and Carr,¹¹ which possibly was affected by secondary reactions. The temperature dependence is based on the measurements of Atkinson and Pitts,² Sims et al.,¹⁴ and Vakhtin et al.¹⁵ Calvert et al. reviewed the data published prior to 2000 and recommended rate constants⁵ in good agreement with the present recommendation. The estimated 2σ error limits are set to include all of the data used in the recommendation. The reaction proceeds mostly (>90%) by addition of OH to the two carbon atoms at the ends of the double bond.⁵ Peeters et al.¹² measured product branching ratios in a multi-stage flow apparatus with mass spectrometric detection and concluded that 85 ± 10% of the OH addition reaction proceeds by addition to the terminal CH₂ group, producing a secondary free radical. Peeters et al. also developed a structure-activity relationship (SAR) for predicting the product distribution for OH + alkene reactions. Loison et al.⁷ also used a flow apparatus with mass spectrometric detection, but with photoionization, and reported that 71 ± 16% of the addition reaction is to the terminal CH₂ group, in good agreement with Peeters et al. Furthermore, Loison et al. concluded that 8 ± 3% of the total reaction is due to abstraction. (Table: 15-10, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

D9. CH₃O + NO. This reaction proceeds via a complex potential energy surface that includes both chemical activation and direct abstraction routes¹ to the disproportionation products CH₂O and HNO as well as the

combination to form CH_3NO . The chemical activation process would have inverse pressure dependence and the direct abstraction would be pressure independent. The recommended values take into account the results of Frost and Smith⁴ in Ar and CF_4 and of Caralp et al.¹ in He and Ar. In both of these references the disproportionation process is subtracted from total loss of CH_3O with a pressure independent, temperature dependent value. At 300 K below one Torr the disproportionation process dominates. Temperature dependences are from the higher temperature results. The low pressure rate constant is consistent with the measurements of McCaulley et al.⁵ and Daële et al.² in helium. Studies by Ohmori et al.⁶ and Dobé et al.³ are in general agreement with respect to both the addition and bimolecular pathways. (See the note in Table 1-1 for the bimolecular pathway.)

D10. $\text{CH}_3\text{O} + \text{NO}_2$. The recommended values are from the work mostly of Wollenhaupt and Crowley (in Ar).⁶ Agreement is good with earlier work at 298 K from the study of Frost and Smith² in Ar (corrected by Frost and Smith³) and that of Biggs et al.¹ and Martinez et al.⁴ in He. Low pressure results agree within a factor of two with the measurements of McCaulley et al.⁵ in He. A minor bimolecular (chemical activation) pathway is also observed. (See Table 1-1.)

Phys. Chem. A* **2000**, *104*, 6429-6438, doi:10.1021/jp0005726.

D11. $\text{C}_2\text{H}_5\text{O} + \text{NO}$. High-pressure data at 298 K in Ar from Frost and Smith³ and in He between 286 and 388 K at pressures from 30 to 500 Torr, from Fitschen et al.² Low-pressure measurements in He are from Daele et al.¹ He experiments were scaled to N_2 by dividing by a factor of 2.5. Ar data were taken as equivalent to N_2 or air. The data were fit by subtracting an assumed pressure independent value of 1×10^{-11} from the measured rate constants to account for the route to form HNO and CH_3CHO . The low-pressure value agrees with theory. The bimolecular channel with an estimated rate constant of about 10^{-11} needs to be verified by direct studies. The temperature dependence of the low pressure limit is estimated and that of the high pressure limit is taken from Fitschen et al.² (The high pressure rate expression in Fitschen et al. seems to be in error.)

- (1) Frost, M. J.; Smith, I. W. M. Rate constants for the reactions of CH_3O and $\text{C}_2\text{H}_5\text{O}$ with NO_2 over a range of temperature and total pressure. *J. Chem. Soc. Faraday Trans.* **1990**, *86*, 1751-1756, doi:10.1039/ft9908601751.

D13. $\text{CH}_3\text{O}_2 + \text{NO}_2$. Golden³ has re-evaluated the data for this reaction. The recommended parameters are from a fit to Percival⁴ and temperature- and pressure-dependent data in Sander and Watson⁶ and Ravishankara et al.⁵ The temperature dependence of the high pressure rate constant is a little high, but results from the statistical fit to the data. The values recommended herein, were taken with the data in a study of the reverse reaction by Zabel et al.⁷ to compute the value of the equilibrium constant in Table 3-1. Destriau and Troe² have fit the above data with k_∞ independent of temperature and $F_c = 0.36$. Bridier et al.¹ are in good agreement with this recommendation at one atmosphere and 298 K.

D14. $\text{C}_2\text{H}_5\text{O}_2 + \text{NO}_2$. The only experimental study is that of Elfers et al.³ who measured the rate constant relative to the $\text{C}_2\text{H}_5\text{O}_2 + \text{NO}$ reaction between 10 and 1000 mbar. Elfers et al. used a value of $k = 8.9 \times 10^{-12} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ for the reference reaction. By comparison the recommended rate constant for the reference reaction from Table 1-1 of this evaluation is $1.1 \times 10^{-11} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ at 254 K. There are three data points. An evaluation of the Elfers et al. work by Destriau and Troe² cast the data in the format used in the IUPAC evaluation.¹ The parameters in Table 2 are adjusted to agree with the data corrected for the change in the reference reaction, using the simpler formula employed in this recommendation.

D15. CH₃C(O)O₂ + NO₂. The recommended parameters are from the data of Bridier et al.,¹ who report in the format represented here, but using $F_c = 0.3$. Their values are: $k_0^{300} = (2.7 \pm 1.5) \times 10^{-28}$, $k_\infty^{300} = (12.1 \pm 2.0) \times 10^{-12}$, with $n = 7.1 \pm 1.7$ and $m = 0.9 \pm 0.15$. Bridier et al. also reported measured rate constants (k_{uni}) for the reverse reaction from 297 to 314 K and pressures from 7 to 600 Torr of N₂. Direct measurements of the recombination rate constant by Sehested et al.⁶ are in excellent agreement with those of Bridier et al. The present recommendation is based on a non-linear least-squares analysis (assuming uniform relative errors) of the direct measurements reported by Bridier et al. for k_{rec} and k_{uni} (the latter multiplied by K_{eq} , which is recommended in Table 3). This recommendation is in very good agreement with previous ones and the 2 σ parameter uncertainties encompass all of the values used in the least-squares analysis. Studies of the decomposition of CH₃C(O)O₂NO₂ (peroxyacetylnitrate, PAN) by Sehested et al.⁶ are in excellent agreement with the recommendation and those by Roberts and Bertman,⁴ Grosjean et al.,² and Orlando et al.³ are in accord. Studies by Seefeld et al.⁵ and Sehested et al.⁶ of the relative rates of CH₃C(O)O₂ with NO and NO₂ are confirmatory. In the Roberts and Bertman⁴ study it was shown that PAN decomposition yields only peroxyacetyl radical and NO₂; methyl nitrate was not detected. However, a study by von Ahsen et al.⁷, which utilized matrix isolation of the PAN decomposition products, suggests a minor pathway due to O-O bond fission.

D16. CH₃CH₂C(O)O₂ + NO₂. This reaction, forming peroxypropionyl nitrate (PPN), has been studied in the reverse direction by Schurath and Wipprecht,⁴ Mineshos and Glavas,³ Grosjean et al.,¹ and Kirchner et al.² Group additivity considerations indicate that the equilibrium constant for both PAN and PPN will be the same (both sides of the equilibrium for PPN differ from those for PAN by the group C-(C)(CO)(H)₂). Therefore, the recommended value for the association reaction is taken from the decomposition studies multiplied by the same equilibrium constant as for PAN. The resulting values are very similar to those for $CH_3C(O)O_2 + NO_2$ forming peroxyacetyl nitrate (PAN). Conservative error limits are estimated.

D17. $\text{CH}_3\text{C}(\text{O})\text{CH}_2 + \text{O}_2$. Cox et al.¹ reported a value of $k = (1.5 \pm 0.3) \times 10^{-12} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ at 298 K and 1 atm of SF_6 in which a pulse radiolysis study was modeled. Studies in He at 298 K have been reported by Oguchi et al.,⁵ Imrik et al.,³ Kovacs et al.,⁴ and Hassouna et al.² This data can be accommodated with $k_0 = 1.5 \times 10^{-29} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$, $k_\infty = 1.0 \times 10^{-12} \text{ s}^{-1}$ with $f = 1.15$. To account for the difference between He and N_2 , $k_0 = 3 \times 10^{-29}$, and $f = 1.3$ are estimated and recommended. Hassouna et al. report rate constants in the temperature range 291 to 400 K at 130 and 650 bar He showing a slight negative temperature dependence. They also report data at 10 bar He in the temperature range 459 to 520 K. These latter data exhibit biexponential decays from which the equilibrium constant is also extracted. (See Table 3-1.)

D18. $\text{CH}_2\text{OO} + \text{CH}_2\text{OO}$ (Criegee intermediate). The recommendation is the average of the rate constants reported near 298 K by Buras et al.¹ and Ting et al.⁶ (the latter supersedes the report of Su et al.⁵). The reaction does not depend on pressure at least up to 1 atmosphere, because of the existence of low energy thresholds for subsequent isomerization and fragmentation.⁷ The reaction products are thought to be $2 \text{ H}_2\text{CO} + \text{O}_2(^1\Delta_g)$. Because of the rapid reactions of CH_2OO and the complex mixtures of reactants present in the systems that have been studied, rate constants must be extracted from complicated mechanisms.^{1-4,6,7} Ting et al.⁶ have presented an analysis using perhaps the most comprehensive mechanism to date, but this field is changing very rapidly.

D19. $\text{OH} + \text{HCN}$. The recommendation is based on the laser flash photolysis-laser induced fluorescence (FP-LIF) measurements of Strekowski.⁶ A study by Fritz et al.² employed a laser flash photolysis-resonance absorption

apparatus. The Fritz et al. results are systematically greater than the Strekowski values. The results of Strekowski are preferred because the LIF technique is less subject to interference than resonance absorption. Furthermore, the activation energy of $k_{\infty}(T)$ measured by Strekowski (~ 13 kJ/mol) is consistent (within the expected error range) with the ab initio value (~ 14 kJ/mol) of Bunkan et al.,¹ while that from Fritz et al. (~ 5 kJ/mol) is not. The uncertainty factor (f) encompasses the data reported by Strekowski et al. and Fritz et al. The results reported by Fritz et al. and Strekowski suggest the reaction to be in the fall-off region under most atmospheric conditions. By contrast, Phillips^{4,5} studied this reaction using a discharge flow apparatus at low pressures and found the rate coefficient to have reached the high pressure limit at ~ 10 Torr at 298 K. The results reported by Fritz et al. and Strekowski contradict this finding. Bunkan et al.¹ report the $^{12}\text{C}/^{13}\text{C}$ and $^{14}\text{N}/^{15}\text{N}$ kinetic isotope effects at 298 K and 1.00 atm to be 0.9733 ± 0.0012 and 0.9840 ± 0.0016 , respectively (uncertainties are 1σ). The reaction mechanism has been investigated theoretically by Galano,³ and Bunkan et al.¹ Galano³ found that, under atmospheric conditions, $\text{HC}(\text{OH})\text{N}$ reacts with O_2 to generate nitroso formaldehyde ($\text{HC}(\text{O})\text{NO}$) and regenerates an OH radical (a finding confirmed by Bunkan et al.¹). Strekowski⁶ showed experimentally that $>80\%$ of the OH is regenerated when 100 Torr of O_2 is present at 295 K. Bunkan et al.¹ used theory to determine that the initial OH addition to the carbon atom in HCN has a barrier of 15.4 kJ/mol; when they adjusted it to 14.3 kJ mol^{-1} , the theoretical rate constant could be brought into agreement with the experiments of Strekowski.⁶ Additional laboratory kinetic studies are desired to validate the Strekowski data and current recommendation.

E1. $\text{F} + \text{O}_2$. Values are taken from a study by Campuzano-Jost et al.,² with experiments from 100 to 420 K at pressures of He, Ar and N_2 from 1 to 1000 bar. (They used $F_c = 0.54(T/300)^{-0.09}$, but the results are essentially the same with $F_c = 0.6$.) A study by Pagsberg et al.⁷ reports k_0 in argon to be $4.38 \times 10^{-33} (T/300)^{-1.2}$. There is also good agreement with earlier values of Smith and Wrigley,⁹ Smith and Wrigley,¹⁰ Shamonina and Kotov,⁸ Arutyunov et al.,¹ Wallington and Nielsen,¹² Wallington et al.,¹¹ and Ellerman et al.⁵ The values are slightly lower than the values of Chen et al.⁴ and Chegodaev et al.³ Lyman and Holland⁶ report a slightly lower value in Ar at 298 K. Campuzano-Jost et al.² and Pagsberg et al.⁷ also determined the equilibrium constant and thus $\Delta H_{f,298}(\text{FO}_2) = 6.13 \pm 0.5 \text{ kcal mol}^{-1}$. See $\text{F} + \text{O}_2$ in Table 3-1.

- E3. F + NO₂.** Fasano and Nogar³ studied this reaction in N_2 at 300 K. Pagsberg et al.⁵ studied the reaction in SF_6 and Zetzsch⁷ studied it in He. The results from Fasano and Nogar³ and Pagsberg et al.⁵ were used to determine both the high and low pressure limits at 300 K. Treatment of the data for this system requires knowledge of the relative stabilities of FNO_2 and $FONO$. Patrick and Golden⁶ assumed that the difference between these would be the same as between the $ClNO_2$ isomers. Theoretical work by Dixon and Christie,² Lee and Rice,⁴ and Amos et al.¹ indicates that FNO_2 is 35–40 kcal mol⁻¹ more stable than $FONO$, and therefore the measured rate refers to FNO_2 formation. The value of $n = 2$ is from Patrick and Golden, but consistent with Pagsberg et al.⁵ who made a few measurements at 341 K. The value of m is a rough estimate from similar reactions, but is also consistent with Pagsberg et al.⁵ (Table: 06-2, Note: 06-2, Evaluated: 06-2) [Back to Table](#)

- E5. CF₃ + O₂.** Caralp et al.³ have measured the rate constant in N₂ between 1 and 10 Torr. This supersedes the value from Caralp and Lesclaux.² Kaiser et al.⁵ have extended the pressure range to 580 Torr measuring the reaction relative to the reaction of CF₃ with Cl₂. Breheny et al.¹ report values at 295 K from 2–110 Torr and they make a cogent argument for lowering the value of the rate constant used by Kaiser et al for their reference reaction by about 50%. This has the effect of lowering the Kaiser values. Each study recommends different parameters, but the data are well represented by the currently recommended values. Data of Ryan and Plumb⁶ are in general agreement. Forst and Caralp⁴ have examined this reaction theoretically.

- E6. CF₃O + NO₂.** Fockenberg et al.² report values (and large error limits) in nitrogen with 250 < T/K < 302 and 7 < P/mbar < 107. Their values, including two sigma errors are: $k_0 = (3.1 \pm 3.0) \times 10^{-28}$; $n = (2.0 \pm 2.0)$; $k_\infty = (1.5 \pm 0.5) \times 10^{-28}$; $m = (2.8 \pm 2.0)$. Because such large values for m are not physically justifiable, the recommendation is based on a fit forcing $m = 1$, which falls within the large error limits. The reaction products reported by Fockenberg et al. agree with those reported by Chen et al.,¹ who used photolysis of CF₃NO to prepare CF₃O₂ and subsequently CF₃O in 700 Torr of air at 297 ± 2 K. They considered two product channels: (a) CF₃ONO₂ obtained via three-body recombination and (b) CF₂O + FNO₂ obtained via fluorine transfer. Both products were observed and found to be thermally stable in their reactor. They report $k_a/(k_a+k_b) > 90\%$ and $k_b/(k_a+k_b) < 10\%$, thus the formation of CF₃ONO₂ is the dominant channel at 700 Torr and 297 K.

- E7. CF₃O₂ + NO₂.** The data are from experiments in O₂ of Caralp et al.,¹ who suggest a somewhat different fitting procedure than used here. A statistical best fit to the data yields a value of $m = 5.7$, but the values recommended

here fit the data just about as well. Destriau and Troe² use yet a different fitting procedure that does not represent the data quite as well as that recommended here. Reverse rate data are given by Köppenkaströ and Zabel.³

E8. CF₃O + CO. Values taken from Turnipseed et al.¹ The numbers were obtained for Ar as the bath gas and are assumed to hold for N₂ as well. The temperature dependence of the high-pressure rate constant was determined over the range 233 < T/K < 332 in SF₆. No temperature dependence of the low-pressure-limiting rate constant was reported. The value in the table is an estimate. Wallington and Ball² report values in good agreement with Turnipseed et al.¹

E9. CF₃O + M. The activation energy for thermal decomposition of CF₃O to CF₂O + F has been reported to be 31 kcal mol⁻¹ by Kennedy and Levy.¹ Thermochemical data yield ΔH°(298) = 23 kcal mol⁻¹. This implies an intrinsic barrier of about 8 kcal mol⁻¹ to elimination of F from CF₃O. Electronic structure calculations by Li and Francisco² support this observation. Adopting the *A*-factor for unimolecular dissociation, *A* = 3 × 10¹⁴ s⁻¹ and *E* = 31 kcal mol⁻¹ from Kennedy and Levy, *k*_∞(298 K) is about 6 × 10⁻⁹ s⁻¹. This corresponds to a lifetime of about 6 years; therefore, thermal decomposition of CF₃O is unimportant throughout the atmosphere.

F1. Cl + O₂. Nicovich et al.³ measured the rate constant at 181 < T/K < 200 and 15 < P/Torr < 40 in O₂. They reported *k*₀ = (9 ± 3) 10⁻³³ cm⁶ molecule⁻² s⁻¹ at T = 187 ± 6 K in O₂. The recommended low-pressure limiting parameters are from fitting their data over the entire range and assuming that O₂ and N₂ bath gases are equivalent. The value from the calculation at 300 K (i.e., 2.2 × 10⁻³³ cm⁶ molecule⁻² s⁻¹) compares with an older value of Nicholas and Norrish² of 1.7 × 10⁻³³ in an N₂ + O₂ mixture. Baer et al.¹ report a value in O₂ of *k*₀ = 1.6 × 10⁻³³(T/300)^{-2.9} cm⁶ molecule⁻² s⁻¹ in good agreement with the value recommended here. They also report a value in N₂ of *k*₀ = 1.4 × 10⁻³³(T/300)^{-3.9} cm⁶ molecule⁻² s⁻¹. A theoretical study by Zhu and Lin⁴ suggests *k*₀ = 1.26 × 10⁻¹⁶ T^{-6.22} exp(-943/T) cm⁶ molecule⁻² s⁻¹ in O₂ (2.0 × 10⁻³³ at 300 K) with *k*_∞(300) = 1.8 × 10⁻¹⁰ s⁻¹, which is adopted here. The Nicovich et al.³ data are so far from the high pressure limit, that the rate constant has little sensitivity to *k*_∞. Baer et al.¹ suggest *k*_∞ = 2.7 × 10⁻¹¹ s⁻¹, but the data suggest a higher value.

- F2. Cl + NO.** Low-pressure limit and temperature dependence is from re-evaluation of data from Lee et al.³ The recommendation is also in good agreement with the data reported by Clark et al.² and by Ashmore and Spencer.¹ (Table: 06-2, Note: 06-2, Evaluated: 06-2) [Back to Table](#)
- (1) Ashmore, P. G.; Spencer, M. S. Concurrent molecular and chlorine atom mechanisms in the reversible dissociation of nitrosyl chloride. *Trans. Faraday Soc.* **1959**, *55*, 1868-1883, doi:10.1039/tf9595501868.

 - (3) Lee, J. H.; Michael, J. V.; Payne, W. A., Jr.; Stief, L. J. The temperature dependence of the rate constant for Cl + NO + N₂ → NOCl + N₂. *J. Chem. Phys.* **1978**, *68*, 5410-5413, doi:10.1063/1.435716.
- F3. Cl + NO₂.** Low-pressure limit at 300 K from Leu⁴ and Ravishankara et al.⁷ The latter study extended the data to 200 Torr in He. A turbulent flow study by Seeley et al.⁹ extended the results to 250 Torr of Ar and the high-pressure limit was chosen to fit these two studies after taking into account differences in collisional efficiencies of the bath gases. Leu⁴ confirms the observation of Niki et al.⁵ that both ClONO and ClNO₂ are formed, with the former dominating. This has been explained by Chang et al.,¹ with detailed calculations in Patrick and Golden.⁶ The temperature dependence is as predicted in Patrick and Golden⁶ and is the same as Leu's results in He. Ravishankara et al.⁷ report a few data points in N₂ that may suggest a somewhat higher temperature dependence. The temperature dependence of the high-pressure limit is estimated. The uncertainty limits are estimated. Master Equation/RRKM studies by Zhu and Lin¹⁰ and by Golden,² using potential energy surfaces computed by Lee,³ Zhu and Lin,¹⁰ and Sayin and McKee⁸, report differences in their ability to fit the data. Zhu and Lin¹⁰ claim to fit, while Golden² finds the calculations to under predict the low pressure data. (Table: 10-6, Note: 10-6, Evaluated: 10-6) [Back to Table](#)

- F6. Cl + C₂H₄.** Values at 300 K are from a relative rate study by Wallington et al.¹⁰ A relative rate study by Kaiser and Wallington⁴ extends the pressure range to 0.3–6000 Torr and is compatible with earlier studies. Temperature dependence of *k*₀ is taken from Kaiser and Wallington.⁵ The temperature dependence of *k*_∞ is estimated. Values are in reasonable agreement with studies by Maricq et al.,⁸ Lee and Rowland,⁷ Iyer et al.,³ Atkinson and Aschmann,¹ Atkinson and Aschmann,² and Wallington et al.¹¹ A study in He by Stutz et al.⁹ is noted, as is a comment on it by Kaiser and Wallington.⁵ Knyazev et al.⁶ have done an extensive experimental and theoretical analysis. Their values agree with this recommendation.

- F7. $\text{Cl} + \text{C}_2\text{Cl}_4$.** The recommendation is from the flash-photolysis study of Nicovich et al.³ carried out at 231–390 K in 3–700 Torr N_2 . A study by Thuner et al.⁴ at 296 K and 2–700 Torr of air is in agreement, although agreement is poorer at pressures below 10 Torr. Results near room temperature and 1 atm by Atkinson and Aschmann¹ and by Morozov et al.² are also consistent. The scatter in the rate constants reported by Nicovich et al. is roughly independent of temperature.

- F8. $\text{ClO} + \text{NO}_2$.** The low-pressure-limit recommendation and uncertainties are based on temperature-dependent values from Zahniser et al.,¹⁵ Lee et al.,⁸ Birks et al.,² Leu et al.,⁹ Wallington and Cox,¹⁴ Cox et al.,³ and Molina et al.¹⁰ All of these data were collected in N_2 bath gas, except for several points from Lee et al.⁸ collected in O_2 . The high-pressure-limit recommendation is based on the RRKM calculations of Smith and Golden.¹² There are several pressure-dependent data sets in the literature, such as Percival et al.,¹¹ Handwerk and Zellner,⁷ Dasch et al.,⁵ and Cox and Lewis;⁴ however, they are too disparate to extract unambiguous values. These data are all reproduced within two-sigma error limits by the current recommendation. However, the value of $m = 1.9$ is somewhat large for a radical-radical process. If $m = 1$ is chosen the computed rate constant is lower by about 20% at 180 K and pressures above 500 Torr. Golden⁶ attempted to fit the data with a master equation analysis and found that the usual energy transfer treatment at low pressures is insufficient to fit the data, but this appears to be due to a coding error.¹ Theoretical work by Zhu and Lin¹⁶ find significant barriers to formation of the two ClOONO conformers from $\text{ClO} + \text{NO}_2$; these barriers are too large to enable formation of ClOONO . Most theoretical work, including rather precise work by Szakacs et al.¹³ indicate that most stable ClOONO isomer is nearly isoenergetic with $\text{ClO} + \text{NO}_2$. Even in the absence of the barriers reported by Zhu and Lin, the thermodynamics make it unlikely that ClOONO would be formed.

F9. OClO + NO₃. Friedl et al.² studied this system at $1 \leq P/\text{Torr} \leq 5$ for helium and $220 \leq T/\text{K} \leq 298$. They deduced values for the rate constant consistent with their data of $k_0 \approx 10^{-31}$ and $k_\infty \approx 10^{-11}$. They also suggest a value for the equilibrium constant: $K/\text{cm}^3 \text{ molecule}^{-1} = 1 \times 10^{-28} \exp(9300/T)$. Boyd et al.¹ raised the question of possible heterogeneous effects in this system. Parthiban et al.³ in a theoretical study, support the finding of Friedl et al.² of the species O₂ClONO₂, but suggest a very different equilibrium constant. (See Table 3-1).

F10. ClO + ClO. The recommendation is based on a global non-linear least squares fit (all data were assumed to have the same relative error) of data from Sander et al.¹⁵ (195–247 K), Nickolaisen et al.¹³ (260–390 K), Bloss et al.³ (183–245 K), Trolrier et al.¹⁹ (200–263 K), Boakes et al.,⁴ and Ferracci and Rowley⁷ (250–312 K). The Trolrier et al. data have been corrected for values at the zero-pressure intercept as suggested in the Trolrier et al. paper. With this adjustment most of the data are in reasonable agreement. Boakes et al.⁴ report higher values and a zero-pressure intercept; they suggest disregarding their data at less than 100 Torr and report preferred parameters of 2.79×10^{-32} ; 3.78; 3.44×10^{-12} ; 1.73. Ferracci and Rowley⁷ studied the reaction only at 760 Torr and found values in agreement with those of Boakes et al. The error limits represent an attempt to include most of the data within the 95% uncertainty band. The major dimerization product is chlorine peroxide (Birk et al.,² DeMore and Tschukow-Roux,⁶ Slanina and Uhlik,¹⁶ Stanton et al.,¹⁷ and Lee et al.¹¹). Golden⁸ has performed RRKM and master equation calculations using the potential energy surface in Zhu and Lin²¹ and concluded that while a channel to form ClOClO might exist, the net yield is probably very small the best representation of the data remains that only a single channel is important. The k_0 value for N₂ is not in accord with a simple

theory as explained in Patrick and Golden¹⁴ and in some detail in Golden⁸ (this finding was probably the result of a bug that was subsequently found in the master equation code). It has been suggested¹⁸ that the "radical-complex" mechanism may apply here, although a study by Liu and Barker¹² suggests otherwise. Other previous rate constant measurements, such as those of Hayman et al.,⁹ Cox and Derwent,⁵ Basco and Hunt,¹ Walker,²⁰ and Johnston et al.,¹⁰ range from $(1-5) \times 10^{-32} \text{ cm}^6 \text{ molecule}^{-2} \text{ s}^{-1}$, with N₂ or O₂ as third bodies. F11. ClO + OClO. Data are from Burkholder et al.,¹ who measured the rate constant in N₂ at 200 ≤ T/K ≤ 260 and densities from $(1.1-10.9) \times 10^{18} \text{ molecules cm}^{-3}$. They also measured the equilibrium constant (See Table 3-

1). Parr et al.³ also report a value for the rate constant in reasonable agreement with the recommendation. Zhu and Lin⁴ report an ab initio study of this system. Their parameters are somewhat different from those herein, but they fit the data equally well. Green et al.² report a value in He that is consistent with the values recommended herein.

F12. O + OCIO. The recommendation is based on data of Colussi et al.² and Colussi,¹ who measured the pressure dependence between 248 and 312 K in Ar. They interpret the intercept of their *k* vs [M] curves as a zero-pressure rate constant of $(1.6 \pm 0.4) \times 10^{-13} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ with a negative activation energy corresponding to a chemical activation channel producing ClO + O₂. This interpretation is supported by a low pressure study by Gleason et al.,³ as well as a theoretical study by Zhu and Lin,⁴ which suggests a direct abstraction with a positive activation energy. (Zhu and Lin⁴ point out that sym-ClO₃ has a positive barrier for dissociation to ClO + O₂.) The recommended values are fit to the data after subtracting the abstraction channel. See Table 1-1.

F15. $\text{CCl}_3 + \text{O}_2$. The recommendation incorporates studies by Fenter et al.,³ Danis et al.,² and Luther et al.⁵ (The data of Luther et al. above 100 bar are affected by slow diffusion.) Experimental data of Ryan and Plumb⁸ have been considered in the evaluation. A study by Nottingham et al.,⁶ in He, is in agreement. Forst and Caralp⁴ have examined this reaction theoretically. A Patrick and Golden-type calculation using the thermochemistry of Russell et al.⁷ yields $k_0^{300} = 1.5 \times 10^{-30}$, with $\beta = 0.3$. A value of $k_\infty^{300} = 5 \times 10^{-12}$ has been reported by Cooper et al.¹ The value of the rate constants recommended here differ only slightly from those of Luther et al., (who report $k_\infty^{300} = 5.2 \times 10^{-12}$; $m = 1.4$ and $k_0^{300} = 1.5 \times 10^{-30}$; $n = -6.3$; $F_c = 0.35 \times (T/300)^{-0.35}$ using the IUPAC formula) but yield an overall rate constant within their error limits.

F16. $\text{CFCl}_2 + \text{O}_2$. Values for both low- and high-pressure limits at 300 K are from Caralp and Lesclaux.¹ Forst and Caralp² have examined this reaction theoretically. Temperature dependences are rough estimates based on their calculations and by analogy with similar reactions.

- (2) Forst, W., and F. Caralp Microcanonical variational theory of radical recombination by inversion of interpolate partition function Part 2.- $\text{CX}_3 + \text{O}_2$ ($\text{X} = \text{H}, \text{F}, \text{Cl}$). *J. Chem. Soc. Faraday Trans.* **1991**, *87*, 2307-2315, doi:10.1039/ft9918702307.

F17. $\text{CF}_2\text{Cl} + \text{O}_2$. The recommended $k_0(300)$ and $k_\infty(300)$ are from the experimental work reported by Codnia and Azcárate,¹ and the recommended temperature exponents are taken from the theoretical predictions of Forst and Caralp.² Codnia and Azcárate used CO_2 laser IR multiphoton dissociation of CF_2Cl_2 to prepare CF_2Cl radicals in the presence of O_2 (and N_2 buffer gas) at 300 K. Subsequent fast reactions produced vibrationally excited CF_2O^* , which they monitored by measuring its spontaneous IR fluorescence near 1928 cm^{-1} . They showed that the growth and decay rates of the IR fluorescence intensity are due to the reactions of CF_2Cl radicals with O_2 and to the rate of collisional deactivation of CF_2O^* . Analysis of the reaction rates between CF_2Cl and O_2 revealed the existence of both the pressure-dependent recombination reaction and a direct bimolecular step (previously proposed by other workers; see Table 1-1) are important in the pressure range from 0 to 20 mbar of N_2 . Separate control of O_2 concentrations enabled them to obtain the rate constant for the direct reaction (Table 1-1), as well as $k_0(300)$ and $k_\infty(300)$ for the recombination. The latter values are in rough agreement with the theoretical predictions of Forst and Caralp,² who predicted temperature exponents in approximate agreement with similar reactions. The estimated errors are relatively large because the reaction has been measured only once at 300 K and because the temperature dependence is based on theoretical predictions.

- F19. $\text{CFCl}_2\text{O}_2 + \text{NO}_2$.** Caralp et al.¹ studied this reaction at 233, 298, and 373 K at pressures of 0.013 to 0.13 atm. The reaction appears to be in the fall-off region. The recommended data are based on a fit with the constraint that $m = 1$. Caralp et al.¹ suggest a different fitting procedure, but the values recommended here fit the data just as well. Destriau and Troe² use yet a different fitting procedure that does not represent the data quite as well as that recommended herein. A study by Jowko et al.³ in 1 atm of SF_6 at room temperature obtained an effective second order rate constant that is 15% lower than the value calculated from this recommendation. Data for the reverse reaction are reported by Köppenkastrup and Zabel.⁴

G1. Br + NO₂. The recommended values are from a study by Kreutter et al.² They regarded the product as BrNO₂. Their k_0 value in He agrees with the measurement of Mellouki et al.⁴ at 300 K. Broske and Zabel¹ and Orlando and Burkholder⁵ have shown that *cis*-BrONO is the major product in their studies. Orlando and Burkholder⁵ suggest that isomerization to BrNO₂ is heterogeneous. Lee³ calculated structure, frequencies and energetics for BrNO₂, *cis*-BrONO and *trans*-BrONO. A Patrick-and-Golden-type calculation using the Lee³ results yields k_0 (strong collision) $\approx$ 1.2, 2.5, and 2.1 in units of $1 \times 10^{-31} \text{ cm}^6 \text{ molecule}^{-2} \text{ s}^{-1}$ for *trans*-BrONO, *cis*-BrONO, and BrNO₂, respectively. The sum, 5.9×10^{-31} , multiplied by a collision efficiency in N₂ of 0.3 is a factor of about 2.5 lower than the observed k_0 value. Also, the relative yield of BrNO₂ is somewhat too high since Orlando and Burkholder⁵ measure BrONO >75%. Kreutter et al.² report an equilibrium constant, which, if *cis*-BrONO is assumed to be the product, suggests bond strengths for the BrONO compounds that are about 4 kcal mole⁻¹ higher than the Lee³ calculation. Computing k_0 with these new values yields $k_0 \approx$ 4.5 and 6.4 in units of 1×10^{-31} for *trans*-BrONO and *cis*-BrONO, respectively. When the sum of the rate constants for the three channels is multiplied by the collision efficiency (0.3), the result is 3.9×10^{-31} and the yield of BrONO is 85%.

G2. BrO + NO₂. Recommended values are from a global least squares fit of data from Thorn et al.¹⁰ and Sander et al.⁹, which are in excellent agreement at 298 K. The recommended values differ only slightly from the previous recommendation. Danis et al.¹ give slightly lower values for the low-pressure-limiting rate constant and a smaller temperature dependence as well. This latter study may be hampered by heterogeneous effects, but can be accommodated within the error limits recommended. A theoretical study by Rayez and Destriau⁸ suggests that the bond-dissociation energy in BrONO₂ is 8.5 kcal mol⁻¹ higher than in ClONO₂, thus rationalizing the relative values of the low-pressure-limiting rate constants for these two processes. A more detailed theoretical study by Parthiban and Lee,⁶ as well as a study by Orlando and Tyndall,⁵ who measured BrONO₂ decomposition and thus an equilibrium constant, both determine only 1.6 kcal mol⁻¹ for the above difference. A theoretical study by Zou et al.¹² agrees with the latter figure. A Patrick and Golden⁷ type calculation, even with the stronger bond of Rayez and Destriau⁸ yields a value for the low pressure limiting rate constant that is smaller than observed. Lessar et al.⁴ calculate a potential energy surface for BrOONO. They find that the BrO-ONO bond strength is of the order of 7 kcal mol⁻¹, which is too weak to have any effect on the overall rate of BrO + NO₂. Walsh and Golden^{2,11} have attempted to fit the data with a master equation analysis and found that the usual energy transfer treatment at low pressures is insufficient to fit the data (this was probably due to a bug that was found in that version of the master equation code). Kreyacy et al.³ analyzed atmospheric data and concluded that the recombination rate constant needed to fit the data near 200 K is smaller than the (previous) recommendation.

G3. $\text{Br} + \text{CH}_2=\text{CHCH}=\text{CH}_2$ (1,3-butadiene). In a comprehensive study of the forward and reverse rates of this reaction (using laser flash photolysis of CF_2Br_2 precursor and atomic resonance fluorescence detection of Br atoms), Laine et al.² determined the recombination rate constant from 227 to 298 K. The products are thought to consist of two isomers, but they were not identified in the experiments. Calculations (G4 method) reported by Laine et al. show that addition of Br to a terminal carbon atom is thermodynamically favored. The rate constants reported by Laine et al.² are about $2\times$ as large as relative measurements at 298 K and 1 bar reported previously by Bierbach et al.¹ Bierbach et al. placed their rate constant on an absolute basis by employing a linked chain of relative rate measurements, which consisted of reactions of Br with 2,3-dimethyl-2-butene, trans-2-butene, propene, and terminated with an absolute rate constant for $\text{Br} + \text{acetaldehyde}$; thus the uncertainties may have accumulated. The current recommendation is based on the parameters measured in the direct experiments of Laine et al.² The recommended 2σ error bars encompass all of the data of Laine et al. (Table: 15-10, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

G4. $\text{Br} + \text{CH}_2=\text{C}(\text{CH}_3)\text{CH}=\text{CH}_2$ (isoprene). In a comprehensive study of the forward and reverse rates of this reaction (using laser flash photolysis of CF_2Br_2 precursor and atomic resonance fluorescence detection of Br atoms), Laine et al.² determined the rate constant from 227 to 298 K. The products may consist of several isomers; calculations (G4 method) reported by Laine et al. show that the energetically most stable isomer is $\text{BrH}_2\text{CC}(\text{CH}_3)\text{CH}=\text{CH}_2$, but the identities of the isomers actually produced in the reaction are not known. Laine et al. also measured the rate constants for the reaction of $\text{Iso-Br} + \text{O}_2$ (see Table 1-1) and for the reaction of $\text{Br} + 1,3\text{-butadiene}$ in both the presence and absence of O_2 . They found that the apparent rate of the latter reaction is affected by the presence of O_2 . Bierbach et al.¹ previously reported relative rate constants at 298 K and 1 bar of air. They placed their rate constants on an absolute basis by employing a linked chain of five relative rate measurements, consisting of reactions of Br with 1,3-butadiene, 2,3-dimethyl-2-butene, trans-2-butene, propene, and terminated with an absolute rate constant for $\text{Br} + \text{acetaldehyde}$; thus the uncertainties may have accumulated. The current recommendation is based on the parameters measured in the direct experiments of Laine et al.² in the absence of O_2 . The recommended 2σ error bars encompass all of the data of Laine et al. (Table: 15-10, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

H2. I + NO₂. Evaluation taken from IUPAC.² The data are from van den Bergh et al.,⁵ Mellouki et al.,³ Buben et al.,¹ and van den Bergh and Troe.⁶ IUPAC uses $F_c = 0.63$, which is essentially the same as the universal value adopted here of $F_c = 0.6$. (No evidence of possible isomers [INO₂ or IONO] is reported.) Error limits transposed to the current format. Tucceri et al.⁴ used laser flash photolysis coupled to resonance-fluorescence detection of I atoms to measure the rate coefficients for the reaction: $I + NO_2 + M \rightarrow INO_2 + M$. Rate coefficients at 298 K when combined with other datasets obtained at higher and lower pressures, were adequately described by a simplified Troe function with the parameters: $k_0(\text{He}, 330 \text{ K}) = 1.48 \times 10^{-31} \text{ cm}^6 \text{ molecule}^{-2} \text{ s}^{-1}$, $F_c(\text{He}) = 0.43$, and $k_\infty = 1.1 \times 10^{-10} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ for He as bath gas. In N₂ (or air) the following parameters were obtained $k_0(\text{N}_2, 300 \text{ K}) = 3.2 \times 10^{-31} \text{ cm}^6 \text{ molecule}^{-2} \text{ s}^{-1}$, $F_c(\text{N}_2) = 0.48$, with $k_\infty = 1.1 \times 10^{-10} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$. These parameters essentially reproduce the values at 300 K from the parameters in the Table.

H3. IO + NO₂. Data from Daykin and Wine,² Hölscher and Zellner,⁵ Allan and Plane,¹ Jenkin and Cox,⁶ and Dillon et al.³ are considered. Dillon et al. suggest that the value from Hölscher and Zellner might be low at 298 K due to regeneration of IO, although their values at lower temperatures are in agreement with others. The recommendation takes this into consideration and accommodates the rest of the data. Two more studies at lower pressures are available, Larin et al.⁸ and Maguin et al.⁹ These latter do not agree very well with the above five studies and have larger experimental errors. The recommended k_0 and k_∞ also agree with a theoretical study by Rayez and Destriau.¹² A computational study by Marshall¹⁰ sets the bond dissociation energy as $\Delta H_0(\text{IO}-\text{NO}_2) = 113.6 \pm 3.1 \text{ kJ mol}^{-1}$ and suggests $k_0 = (5.3-13.3) \times 10^{-31} \text{ cm}^6 \text{ molecule}^{-1} \text{ s}^{-1}$ for N₂ as the bath gas, while an ME/RRKM study by Golden⁴ required $\Delta H_0(\text{IO}-\text{NO}_2) \sim 150 \text{ kJ mol}^{-1}$ to fit the data. Papayannis and Kosmas¹¹ compute $\Delta H_0(\text{IO}-\text{NO}_2) = 137.6$ or $131.7 \text{ kJ mol}^{-1}$, depending on spin orbit coupling corrections in IO. A computational study by Koltsoyannis and Plane⁷ concludes that $\Delta H_0(\text{IO}-\text{NO}_2) = 117.9 \text{ kJ mol}^{-1}$. See Table 3-1 for the recommended K_{eq} .

H4. $\text{CH}_2\text{I} + \text{O}_2$. The recommendation at 298 K is the average of measurements by Masaki et al.,⁵ Eskola et al.,² Huang et al.,³ Sheps,⁶ and Stone et al.⁷ Evidently, there is no pressure dependence up to at least 1 atm. The recommendation for the temperature dependence is taken from Eskola et al.² Among other products, this reaction produces significant yields of thermalized formaldehyde oxide (CH_2OO , the simplest carbonyl oxide, also known as a Criegee Intermediate).¹ Yields of CH_2OO in this reaction under one atmosphere of air near 300 K have been reported to be 0.15 ± 0.03 ,^{3,4} ~ 0.18 ,⁷ and ~ 0.30 .⁸

II. $\text{HS} + \text{NO}$. Data are from the work of Black et al.¹ The temperature dependence of k_∞ has been estimated and k_0 has been adjusted to fit the data.
(Table: 06-2, Note: 06-2, Evaluated: 06-2) [Back to Table](#)

- (1) Black, G.; Patrick, R.; Jusinski, L. E.; Slinger, T. G. Rate coefficients for the reaction $\text{HS} + \text{NO} + \text{M} (\text{M} = \text{He}, \text{Ar}, \text{and } \text{N}_2)$ over the temperature range 250- 445 K. *J. Chem. Phys.* **1984**, *80*, 4065-4070, doi:10.1063/1.447287.

- 12. CH₃S + NO.** The recommended values are fit to the study by Balla et al.¹ The temperature range was 295 to 453 K and pressures of N₂ from 1.5 to 300 Torr. The recommended high-pressure limiting rate coefficient and temperature dependence provide a better fit to the data than reported by Balla et al.
(Table: 06-2, Note: 06-2, Evaluated: 06-2) [Back to Table](#)
- (1) Balla, R. J.; Nelson, H. H.; McDonald, J. R. Kinetics of the reaction of CH₃S with NO, NO₂ and O₂. *Chem. Phys.* **1986**, *109*, 101-107, doi:10.1016/0301-0104(86)80188-4.
- 13. O + SO₂.** Naidoo et al.⁴ studied this spin-forbidden reaction in Ar over the temperature range 290 < T/K < 840 and pressure range 100 < P/mbar < 880. They fit the data very well using the IUPAC¹ format with $k_0 = 9.5 \times 10^{-23} T^{-3} \exp(-2400/T) \text{ cm}^6 \text{ molecule}^{-2} \text{ s}^{-1}$, $k_\infty = 6.1 \times 10^{-13} \exp(-850/T) \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ and $F_c = 0.558 \exp(-T/316) + 0.442 \exp(-T/7442)$. The recommended values transpose the rate constants to the form used in this evaluation and are used with the standard value of $F_c = 0.6$. These parameters do not fit the higher temperatures as well as the values derived by Naidoo et al. (i.e. missing the values at 840 K by about 50% and those at 699 K by about 20%), but values at 289, 399 and 581 K are fit quite well and are adequate for atmospheric conditions. Earlier values are reported by Atkinson and Pitts² and Müller et al.³

- 14. OH + SO₂.** The data for this reaction have been completely re-analyzed. The JPL10-15 recommendation was based on the results of Blitz et al.,⁴ who determined the high pressure limit from measurements of OH(v=1) + SO₂ and fitted data by using a master equation approach. Recently, new results obtained by Blitz et al.⁶ for OH(v=1,2,3) + SO₂ suggest that determination of the high pressure limit by using vibrational relaxation of OH(v) is more complicated than had been previously assumed.^{4,11} The new findings by Blitz et al.⁶ and Medeiros et al.¹⁶ for $k_\infty(298 \text{ K})$ ($7 \pm 3 \times 10^{-13}$ and $5.9 \pm 0.8 \times 10^{-13}$, respectively) are a factor of 2–3 lower than most of the older data for this reaction. Blitz et al.⁵ speculate that the older data are in error because of reactions of OH with SO₂ photolysis products in the flash photolysis experiments and regeneration of OH by secondary reactions in the flow tube experiments. Although Blitz et al.⁶ did not offer any quantitative analysis in support of their reasoning, they rejected most of the older data and chose to retain only their own data, the measurements by Cox et al.,⁷ and the data obtained by Wine et al.²⁴ in Ar bath gas (discarding data in He, N₂, and SF₆). The interpretation of Blitz et al.^{5,6} is predicated on the existence of a pre-reactive complex, the existence of which is supported by theoretical calculations.^{16,17} Their analysis is based on the premise that the capture rate constant for adduct formation is independent of the vibrational level of OH(v) and on the assumption that the measured rate constant for loss of OH(v) is due to both adduct formation and impulsive vibrational energy transfer, as described by Shin's extension of SSH theory.¹⁹⁻²² Because these processes are not yet fully understood in this system and the analysis of Blitz and co-workers^{5,6,16} is based on several simplifying assumptions, the reliability of the new interpretation cannot be determined. However, the measured deactivation rate constants of OH(v) may still be regarded as approximate upper limits to $k_\infty(T)$ for the recombination reaction.
The present recommendations for $k_\infty(298 \text{ K})$ and $k_0(298 \text{ K})$ are based on a global non-linear least squares analysis of the experimental data (assuming uniform relative errors) for N₂ and O₂ collider gases near 298 K reported by Cox et al.⁷ (with the measured relative rate constant corrected for current recommendations for the HO + CO reference reaction), Leu,¹³ Wine et al.,²⁴ and Paraskevopoulos et al.¹⁸ In their experiments, Wine et al.²⁴ and Paraskevopoulos et al.¹⁸ used an SO₂ gas filter between the flash lamp and the reaction cell to attenuate wavelengths that might photolyze SO₂ in the reaction cell. When O₂ bath gas was studied by Leu,¹³ there was some evidence that OH was being regenerated by secondary reactions; in that instance, Leu utilized the initial rate, which minimizes the effect. Because their data for O₂ and N₂ are in unexpected disagreement with each other, which possibly suggests the effects of secondary reactions,⁵ the data of Lee et al.¹² were not included, although their results for N₂ are in good agreement with the recommendation. Data from Fulle et al.⁸ were not included in the analysis, because in the relevant pressure range they are significantly higher than all of the other data.

The recommended value for $k_{\infty}(298\text{ K})$ is consistent with regarding the measured rate constants for OH(ν) deactivation as upper limits. The theoretical analysis of Somnitz,²³ the density functional theory calculations of Medeiros et al.¹⁶, and the ab initio high level theoretical calculations of Long et al.¹⁵ consistently predict that the reaction has a small intrinsic activation barrier of ~ 0.5 kcal/mol above the energy of the separate reactants. The recommended $k_{\infty}(298\text{ K})$ is in reasonable agreement with the value (1.26×10^{-12}) computed by Long et al.¹⁵. The recommended temperature exponent for $k_{\infty}(T)$ is based on the value predicted by Long et al.¹⁵, multiplied by an adjustment factor of $\exp(90/T)$ to bring their value of $k_{\infty}(298\text{ K})$ into agreement with the recommendation. This adjustment corresponds to lowering the predicted activation energy to ~ 0.3 kcal/mol. Data for N₂ and O₂ collider gases are available only near 298 K. The present recommendation for the low pressure temperature exponent was taken from the master equation analysis of Blitz et al.,⁴ who re-evaluated the data of Wine et al.²⁴ (which are in very good agreement with the data of Paraskevopoulos et al.¹⁸) in several bath gases at pressures up to 150 Torr and temperatures between 260 and 420 K. The large error factor, $f(298\text{ K}) = 3$, is a result of the uncertainty introduced by the studies by Blitz and coworkers; the much smaller uncertainty, $f(298\text{ K}) = 1.08$, is based on the least-squares analysis leading to the recommended parameters. The value for g applies mostly to the low-pressure limit. Earlier data listed in Harris and Wayne,¹⁰ Harris et al.,⁹ Baulch et al.,³ Baulch et al.,² and Atkinson et al.¹ are noted. Blitz et al.⁴ have calculated the entropy and measured a third law heat of formation for HOSO₂ (373 ± 6 kJ/mol). Medeiros et al.¹⁶ have analyzed a set of selected data and compared heat of formation obtained from several different theoretical studies. See also Li and McKee.¹⁴

- 15. CH₃S + O₂.** The Panel makes no recommendation, since only one direct measurement of the rate constant has been reported and helium bath gas is not appropriate for the atmosphere. The following is for information, only.
- Turnipseed et al.⁴ generated CH₃S radicals by pulsed laser photolysis of CH₃SCH₃ with O₂ in excess and used LIF of CH₃S to monitor the subsequent reaction. Biexponential decays were observed, signaling the reversible formation of a weakly bound complex. They obtained forward and reverse rate constants in 80 Torr of He bath gas at temperatures from 216 to 250 K; the values of $K_{eq} = k_{rec}/k_{uni}$ are in good agreement with the recommended K_{eq} (see Table 3-1). Assuming that k_{rec} is near the low-pressure limit, the data of Turnipseed et al. are described by $k_0(T) = 8 \times 10^{-32} (T/298)^{-5.7}$ in helium bath gas. The reaction has been implicated in three indirect studies,¹⁻³ which reported estimated ratios of rate constants.

- 16. CH₃SCH₂ + O₂.** Wallington et al.² have employed a pulse radiolysis technique, obtaining $k = (5.7 \pm 0.4) \times 10^{-12} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ in 992 mbar of SF₆ at room temperature. A theoretical study by Resende and De Alemeida¹ yields a heat of formation of the product, CH₃SCH₂O₂, as 6.51 kcal mol⁻¹.

Phys. Chem.* **1993**, *97*, 8442-8449, doi:10.1021/j100134a013.
- 17. CH₃ + SO₃.** (Also see Table 3-1) Because this reaction has never been investigated in laboratory experiments, the Panel makes no specific recommendation, but notes that the reaction has been investigated in theoretical studies. The results depend on both the level of theory and the size of the basis set. Salta et al.² commented that composite methods (e.g. G2, G3, and CBS-QB3) seem to be somewhat more reliable for this reaction than

single-point methods like B3LYP and CCSD(T), probably because the composite methods employ both high-level theory and empirical corrections for various effects. They prefer CBS-QB3 because it extrapolates to the complete basis set limit. For a summary of reported reaction enthalpies, which are uncertain, see the Note for this reaction in Table 3. Using a composite method (G3XMP2// B3LYP/6-311+G(3df,2p)), Cao et al.¹ found 63.5 kJ/mol for $\Delta_f H_0$ for $\text{CH}_3\text{SO}_3 \rightarrow \text{CH}_3 + \text{SO}_3$ and a small intrinsic energy barrier (1.0 kJ/mol, including zero point energy); they report the total rate constant for dissociation is $k_{\text{uni}} = (1.40 \times 10^{12}) \times (T^{0.15}) \times \exp(-7831/T) \text{ s}^{-1}$. This rate constant may be too large, however, since $\Delta_f H_0(\text{CH}_3\text{SO}_3)$ reported by Cao et al.¹ is ~ 10 kJ/mol lower than computed by Salta et al.² and by Zhu et al.³ using CBS-QB3. From the molecular parameters for CH_3 , SO_3 , and the transition state reported by Cao et al.,¹ we obtain $k_{\text{rec}}(T) = 2.2 \times 10^{-13} \times (T/298)^{-0.2} \text{ cm}^3 \text{ s}^{-1}$. This value will not be affected by differences in the computed dissociation energy. Because the magnitude of the rate constant depends on the accuracy of geometrical parameters (symmetry and rotational constants), vibrational frequencies (which may be affected by anharmonicity), and computed barrier heights, we estimate an uncertainty factor $f(298 \text{ K}) = 10$ for $k_x(298 \text{ K})$. The reaction is probably close to the high-pressure limit at 1 atm.

- 18. $\text{SO}_3 + \text{NH}_3$.** Recommendation is from Lovejoy.¹ This study covered 20–80 Torr from 280–340 K. An earlier study by Lovejoy and Hanson,² who studied this reaction from 10–400 Torr N_2 at 295 K is in agreement. Lovejoy and Hanson² observed that any incipient adduct rapidly becomes sulfamic acid (H_3NSO_3) which clusters efficiently with itself and sulfuric acid. The observed sulfamic acid dimerization rate constant exceeds $5 \times 10^{-11} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$. Measurements of Shen et al.³ at 1–2 Torr He are much higher than those of Lovejoy and Hanson² or Lovejoy.¹ Error limits have been adjusted to take into account the fact that the exponent of the temperature dependence of the low pressure rate constant is unusually large. Lovejoy¹ also reports an equilibrium constant and heat of formation of sulfamic acid of $-24 \pm 1 \text{ kcal mol}^{-1}$.

- 19. $\text{HO} + \text{CS}_2$.** The data are from Hynes et al.³ and Murrells et al.⁴ The value $m = 1$ is constrained. The recommended rate constant is in reasonable agreement with the measurement of Bulatov et al.¹ Petris et al.² report experimental detection of CS_2OH . See Table 3-1 for the recommended equilibrium constant. The adduct reacts slowly with O_2 . (See Table 1-1).

Chem.* **1990**, 94, 2381-2386, doi:10.1021/j100369a036.

- 110. $\text{Cl} + \text{CS}_2$.** The data are from Nicovich et al.² Wallington et al.³ have also studied this system. The value $m = 0$ is constrained. Nicovich et al.² confirm that the reaction proceeds via reversible adduct formation as suggested by Martin et al.¹ The much larger rate constant values determined by Martin et al. may possibly be

attributed to reactive impurities in the CS₂ sample. Nicovich et al. set an upper limit on the rate constant for the adduct (CS₂Cl) reacting with O₂ of 2.5×10^{-16} cm³ molecule⁻¹ s⁻¹ at room temperature. Wang and Phillips⁴ have reported a theoretical study of the adduct.

II1. OH + CH₃SCH₃ → (CH₃)₂SOH → products. The OH + CH₃SCH₃ reaction is complex, proceeding by both direct H-abstraction and reversible addition pathways. A recommendation for the direct reaction is discussed separately in Table 1-1. The product of the reversible addition pathway reacts with O₂ creating an irreversible path as well. Mechanistically, this pathway is described by combining the rate constants *k_f* for the addition step, *k_r* for the reverse dissociation step, and *k_{O2}* for the adduct reaction with O₂. This is discussed in detail in the notes for Table 1-1. The equilibrium constant for the reversible addition process is *K_c* = *k_f*/*k_r*. Recommendations for *K_c* and *k_{O2}* are found in Tables 3-1, and 1-1, respectively. The value for *k_r* recommended here is from Williams et al.¹ The discussion in Table 1-1 points out that this value taken with *K_c* and *k_{O2}* fits the extant data very well.

(Table: 10-6; Note: 10-6; Evaluated: 10-6) [Back to Table](#)

Phys. Chem. A* **2009**, *113*, 6697-6709, doi:10.1021/Jp9010668.

II2. Cl + (CH₃)₂S. [See Table 1-1] If the HCl yield at 297 K from Stickel et al.⁴ is used as a measure of the abstraction reaction, the rate constant would be 1.64×10^{-10} cm³ molecule⁻¹ s⁻¹. Using this value the complete data set from Stickel et al.⁴ can be fit with the form used in Table 2-1 with the addition of a term for the abstraction in the form *k_{abs}* = $1.64 \times 10^{-10} (T/300)^a$. The value of “a” obtained in this manner is almost zero, so the data are fit with: *k₀* = $4 \times 10^{-28} (T/300)^{-7.0}$ and *k_∞* = $2 \times 10^{-10} (T/300)^{-1}$ along with the temperature independent value of *k_{abs}*. These parameters are recommended herein. Enami et al.² propose *k₀* = 2.2×10^{-28} and *k_∞* = 2.2×10^{-10} at 298 K along with *k_{abs}* = 1.8×10^{-10} . On the other hand, a study by Diaz-de-Mera et al.¹ performed in the temperature range 259 < T/K < 364 and in helium at pressures of 0.5 < P/Torr < 1 reports a value *k_{abs}* = $(2.0 \pm 1.2) \times 10^{-10} \exp[-(332 \pm 173)/T]$, which yields 6.6×10^{-11} cm³ molecule⁻¹ s⁻¹ at room temperature. Several studies, both experimental by Urbanski and Wine⁵ and theoretical by Resende and De Almeida³ make it clear that at higher pressures an adduct Cl-S(CH₃)₂ is formed and this adduct does not yield CH₃ radicals or the products of the abstraction pathway.

I13. Br + (CH₃)₂S. Wine et al.⁵ data for the adduct formation in N₂ at 25 < P/Torr < 600 and 263 < T/K < 310 are the basis for the recommendation. Studies by Ingham et al.² and Nakano et al.⁴ are in agreement. Nakano et al.⁴ is also in agreement with the value of the equilibrium constant. However, Maurer et al.³ find a value at 300 K and 1 bar total pressure of a mixture of 5% O₂ and 95% N₂, only 2% as high as the value computed from the recommended parameters. This latter value is supported by Ballesteros et al.¹

J1. Na + O₂. A study by Plane and Rajasekhar³ finds $k_0 = (2.9 \pm 0.7) \times 10^{-30} \text{ cm}^6 \text{ molecule}^{-2} \text{ s}^{-1}$ at 300 K with $n = 1.30 \pm 0.04$. They also estimate k_∞ to be about $6 \times 10^{-10} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ with a small positive temperature dependence. Another study by Helmer and Plane¹ yields $k_0 = (3.1 \pm 0.2) \times 10^{-30} \text{ cm}^6 \text{ molecule}^{-2} \text{ s}^{-1}$ at 300 K with $n = 1.52 \pm 0.27$. The recommended values are taken from these studies. They are consistent with values measured by Marshall et al.² at 600 K and those measured by Vinckier et al.⁵ at higher temperature. The k_0 value is about 60% higher than that of Silver et al.⁴

J2. Na + OH. This reaction was studied experimentally by Husain et al.² at 653 K in He. Jensen and Jones³ inferred rate constants from Na-seeded flames at 1800-2200 K. Gómez-Martín et al.¹ applied theory to fit both sets of experimental data and obtained $k_0(T) = 2.4 \times 10^{-29} (T/298)^{-1.3} \text{ cm}^6 \text{ molecule}^{-2} \text{ s}^{-1}$ in N₂ over the range 300-2400 K. They also estimated $k_\infty(T) = 9.4 \times 10^{-10} (T/300)^{0.2} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ from a simple model. The only thermodynamically feasible product is NaOH.

- J3. NaO + O₂.** Ager and Howard¹ have measured the low-pressure limit at room temperature in several bath gases. Their value in N₂ is used in the recommendation. They performed a Troe calculation, as per Patrick and Golden², to obtain collision efficiency and temperature dependence. They obtained a high-pressure-limit rate constant by use of a simple model. The temperature dependence is estimated.

- J4. NaO + CO₂.** The recommendation is based on the work of Ager and Howard,¹ who measured the rate constant for this process in the “fall-off” regime and close to the low-pressure limit. The temperature dependence of k_0 is an estimate guided by the simulation results of Gómez Martín et al.² Ager and Howard calculated the high-pressure rate constant from a simple model. Gómez Martín et al. fit the data of Ager and Howard with an RRKM/Master Equation simulation and obtained $k_0(300)$ about 40% higher than Ager and Howard. The temperature dependence of k_∞ is taken from the assumption of a long range (R⁻⁶) attractive potential, as used by Gómez Martín et al.

- J5. NaOH + CO₂.** Ager and Howard¹ studied this reaction experimentally at 0.4–1.5 Torr in N₂/N₂O mixtures at 298 K. They detected NaOH by reacting it with atomic H to form Na, which was detected by resonance fluorescence. They reported a rate constant corrected for the effects of N₂O. Gomez Martin et al.² studied this reaction in 1–4 Torr N₂ and 300 K (and 2 Torr and 266 K) by photoionization time-of-flight mass spectrometry. Results of both sets of experiments are compatible with the reaction being in the low-pressure limit, but the value of $k_0(298)$ obtained by Gómez Martín et al. is about one-half that of Ager and Howard (for N₂ as the sole bath gas). However, Master Equation simulations by Gómez Martín et al. suggest that the reaction is not in the low-pressure limit under the conditions of their experiment. Both groups used simple models to obtain very similar estimates of $k_\infty(298\text{ K})$. The recommendation for $k_0(298)$ is based on the average of the two sets of experimental results. The temperature dependence of k_0 is an estimate guided by the simulation results of Gómez Martín et al. The temperature-dependence of k_∞ is taken from the assumption of a long range (R⁻⁶) attractive potential, as used by Gómez Martín et al.

- J6. Hg + Br.** The recommendation is based on the direct experiments of Donohoue et al.,³ who used pulsed laser photolysis of Br₂ to generate an excess of Br atoms, which reacted with Hg⁰ vapor; the Hg⁰ and atomic Br were monitored simultaneously by pulsed laser induced fluorescence techniques. The recombination reaction rate constant at the low-pressure limit was measured in N₂ gas at temperatures from 243 to 293 K and N₂ pressures from 200 to 600 Torr (measurements were also carried out using He gas). In earlier studies, Greig et al.⁶ analyzed the UV spectrum of HgBr and used their measured absorption coefficients to determine the recombination rate constant from 393 to 448 K in 200 Torr of CF₃Br (conditions not relevant to the atmosphere). Ariya et al.,² Spicer et al.,⁹ and Sun et al.,¹⁰ used relative rate techniques to obtain the rate constant. The first two studies are discussed in detail by Donohoue et al.,³ who concluded that they were seriously affected by secondary reactions. Several theoretical calculations have been reported.^{4,5,7,8,11} In particular, Goodsite et al.⁴ used spectroscopic data, quantum chemistry calculations, and RRKM modeling to obtain theoretical rate constants. Later, using a corrected bond dissociation energy, they repeated the calculations⁵ and showed that with a reasonable choice of an energy transfer parameter, the RRKM results are in very good agreement with the experiments of Donohoue et al.³ A review of Hg atmospheric chemistry has appeared.¹

J7. $\text{HgBr} + \text{HO}_2$. The only data are from a theoretical study by Jiao and Dibble.¹ From their CASPT2 data we fit $k_\infty(T)$ to a power law to obtain $k_\infty(T) = 6.9 \times 10^{-11} (T/298)^{-2.4}$. These results are highly uncertain: perhaps by a factor of 3 ($f = 3$). Values in the low-pressure limit depend on assumed values of Lennard-Jones parameters and energy transfer (ΔE_{down}), which could lead to errors in k_0 of perhaps an additional factor of 3 ($f = 3$). Fitting the effective second order rate constants published by Jiao and Dibble to Equation 2.3 gives an expression of $k_0(T) = 2.3 \times 10^{-29} (T/298)^{-4.4}$. Their studies found sufficiently low rate constants to rule out significant formation of $\text{Hg} + \text{HOBr}$ or $\text{BrHgH} + \text{O}_2$ under tropospheric or stratospheric conditions. The formation of $\text{BrHgO} + \text{OH}$ appears to be endothermic by 5 kcal/mole, which renders it negligible. This discussion is provided for the purposes of model evaluation only and does not constitute a recommendation by the Panel.

J8. $\text{HgBr} + \text{NO}_2$. The only data are from a theoretical study by Jiao and Dibble.¹ Their calculations indicate that significant amounts of the BrHgNO_2 isomer will also form, but will isomerize to more stable *syn*- BrHgONO in seconds or less. They suggest ~10% formation of $\text{Hg} + \text{BrNO}_2$ from these reactants. From their CASPT2 data we fit $k_\infty(T)$ to a power law to obtain $k_\infty(T) = 1.2 \times 10^{-10} (T/298)^{-1.9}$. These results are highly uncertain: perhaps by a factor of 3 ($f = 3$). Values in the low-pressure limit depend on assumed values of Lennard-Jones parameters and energy transfer (ΔE_{down}), which could lead to errors in k_0 of perhaps an additional factor of 3 ($f = 3$). Fitting to Equation 2.3 gives an expression of $k_0(T) = 7.1 \times 10^{-29} (T/298)^{-4.5}$. This discussion is provided for the purposes of model evaluation only and does not constitute a recommendation by the Panel.

2.8 Notes for Table 2-2: Chemical Activation Reactions

K1. O + NO₂. The recommended values are based on separate non-linear least squares analyses of (a) the total rate constant measured at low pressure over a range of temperatures and (b) the association rate constant for producing NO₃ measured at higher pressures. The measurements at low pressures (≤ 100 Torr in He, Ar, or N₂) consist of the those performed over a range of temperatures by Estupiñán et al.,⁶ Gierczak et al.,⁸ Ongstad and Birks,¹⁰ Slanger et al.,¹³ Geers-Muller and Stuhl,⁷ and Avallone,¹ and the room temperature study of Paulson et al.¹¹ In the studies of Estupiñán et al.⁶ and Gierczak et al.,⁸ special emphasis was placed on accurate measurement of the NO₂ concentration and on measurements at low temperatures. The results of earlier studies by Davis et al.⁵ and Bemand et al.³ were not used in deriving the recommended values either because of possible complications from decomposition of NO₂ at higher temperatures or lack of direct NO₂ detection. The higher pressure studies consisted of those performed over a range of temperatures by Burkholder and Ravishankara⁴ and by Hahn et al.⁹ Near 300 K the highest pressure of Burkholder and Ravishankara is just a little lower than the lowest pressure studied by Hahn et al., but the rate constants reported by the latter are smaller by a factor of 2.2. Hahn et al.⁹ cautioned that their results are less reliable at lower pressures, but the high pressure limit is more accurately known. Shiekh et al.¹² investigated the potential energy surface for the reaction using high level quantum chemistry methods and computed rate constants in reasonable agreement with the experiments.

The present recommendation at intermediate and high pressures is based on a least squares analysis of the data of Burkholder and Ravishankara,⁴ constrained by the high pressure limit reported by Hahn et al.⁹ The recommendation, which includes the measurements of Avallone,¹ is in good agreement with previous recommendations from this Panel and with the evaluation of Baulch et al.,² which fits the Hahn et al. values very well. It is also in reasonable agreement with parameters suggested by Burkholder and Ravishankara⁴ and by Hahn et al.⁹ The uncertainty factors listed in Table 2.2 are for the total rate constant, which has only been measured at relatively low pressures. The uncertainty factors increase with pressure, however, because the error parameters for the rate of production of NO₃ are estimated to be $f_{\text{rec}}(298) = 1.35$ and $g_{\text{rec}} = 100$.

K2. OH + HONO₂. The recommendation is based on the data sets reported by Connell and Howard,³ Brown et al.,² Dulitz et al.,⁵ and Winiberg et al.¹⁰ The first of these is the only data set at low pressure (assuming that the collision efficiency of He is 38% of that for N₂^{2,5}) and the other three studies are extensive both in the range and numbers of T,P (N₂ bath gas) combinations investigated. Connell and Howard³ used a discharge flow apparatus with resonance fluorescence detection of OH radicals and UV absorption measurements of HONO₂. Brown et al.² performed rate constant measurements by using laser flash photolysis and HONO₂ concentrations obtained by UV absorption in an in-line absorption cell downstream from the reaction cell. Dulitz et al.⁵ and Winiberg et al.¹⁰ also used laser flash photolysis, but measured the HONO₂ concentrations in situ by different spectroscopic methods. In these two latter studies, measurements at extreme low temperatures were hampered by condensation of HONO₂ on the optical windows; this problem was apparently not as serious in the apparatus used by Brown et al.² Dulitz et al.⁵ and Winiberg et al.¹⁰ also found that their ex situ concentration measurements were subject to systematic errors (probably due to wall-deposition of HONO₂). The reported rate constants are similar in all three studies, but small systematic differences are apparent. Brown et al.,² Dulitz et al.,⁵ and Winiberg et al.¹⁰ analyzed their results in terms of the mechanism proposed by Smith et al.,⁷ involving the formation of a bound, relatively long-lived HO•HONO₂ complex, in addition to the direct reaction channel forming H₂O + NO₃. Studies of the effects of isotopic substitution on the reactions OD + DNO₃, OH + DNO₃, OD + HNO₃, and ¹⁸OH + HNO₃ by Brown et al.¹ support the existence of an intermediate consisting of an H-bonded six-membered ring.

The isotopic studies of Brown et al.¹ and the theoretical calculations of Xia and Lin¹¹ support the assumption that the stabilized OH•HONO₂ complex ultimately reacts under atmospheric conditions to produce H₂O + NO₃. Thus, the effective reaction yield of NO₃ (per OH removed) is assumed to be unity at all temperatures and pressures. A global non-linear least squares analysis was performed in which all samples were first assumed to have identical relative errors, which were adjusted so that each of the four data sets had approximately equal weight. Because the number of data points differed widely in the four data sets (from 8 to 85), approximately equal weighting of the four sets was achieved by multiplying the relative error for each data point in a given data set by the square root of the number of data points in the set to which it belongs. The recommended rate constants are in good agreement with the four data sets used in the least squares analysis and in fair to good agreement with the data sets reported by Wine et al.,⁹ Stachnik et al.,⁸ Devolder et al.,⁴ and Margitan and Watson.⁶ The estimated error factors are based on fits to the data used in the least squares analysis.

K3. HO + CO. This reaction proceeds via initial formation of a chemically activated HOCO* intermediate, which can re-dissociate to HO + CO, dissociate to H + CO₂, and be collisionally stabilized to yield thermalized HOCO. In the presence of O₂, the H + CO₂ product set and the HOCO intermediate are both converted to HO₂ + CO₂ (DeMore,⁹ Miyoshi et al.¹⁷). Miyoshi et al. report a rate constant for the reaction HOCO + O₂ → HO₂ + CO₂ of $\sim 1.5 \times 10^{-12} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ at 298 K (recommended Arrhenius parameters are given in Table 1-1). Therefore, for atmospheric purposes, the products can be taken to be HO₂ and CO₂. The recommended parameters are based on data from McCabe et al.¹⁶ and Liu and Sander,¹⁵ because these two comprehensive studies extended to much lower temperatures than the others. The parameters were obtained by taking the k_{∞} parameters from Senosiain et al.²⁵ (as in previous recommendations) and then performing non-linear least squares fits to Eq. 2-5e, assuming uniform relative errors. The results from the two data sets were averaged to obtain the recommendation. The resulting fit is very similar to previous recommendations, except that the mathematical representation is both more efficient and slightly more accurate. Pressure and temperature dependent data from McCabe et al.,¹⁶ Hynes et al.,¹³ and Liu and Sander¹⁵ are very well represented by the recommended parameters. The estimated error fraction, $f(T)$, is based on the fits to the data of McCabe et al.¹⁶ and Liu and Sander.¹⁵ This reaction has been studied often by many workers. In general, the results are in keeping with the current recommendation. Values have been reported by Dreier and Wolfrum,¹⁰ Husain et al.,¹² Ravishankara and Thompson,²⁴ Paraskevopoulos and Irwin,²² Hofzumahaus and Stuhl.¹¹ The results of Jonah et al.¹⁴ are too high and were not included. An increase in k with pressure has been observed by a large number of investigators, including Overend and Paraskevopoulos,²⁰ Perry et al.,²³ Chan et al.,⁷ Biermann et al.,² Cox et al.,⁸ Butler et al.,⁶ Paraskevop and Irwin,^{21,22} DeMore,⁹ Hofzumahaus and Stuhl,¹¹ Hynes et al.,¹³ McCabe et al.,¹⁶ and Liu and Sander.¹⁵ In addition, Niki et al.¹⁹ have measured k relative to OH + C₂H₄ in one atmosphere of air by following CO₂ production using FTIR.

Previous controversy regarding the effect of small amounts of O₂ (Biermann et al.²) has been resolved and is attributed to secondary reactions (DeMore,⁹ Hofzumahaus and Stuhl¹¹). Liu and Sander¹⁵ have demonstrated that modest levels of O₂ do not interfere with measuring the total rate constant. Currently, there are no indications to suggest that the presence of O₂ has any effect on the rate coefficient other than as a third body. The rate constant measurements (relative to OH + isobutane) of Butler et al.⁶ were re-evaluated in the light of refinements in the rate coefficient for the OH + isobutane reaction; the corrected rate coefficient is in approximate agreement with the recommended value. Beno et al.¹ observe an enhancement of k with water vapor, which is in conflict with the flash photolysis studies; e.g. Ravishankara and Thompson,²⁴ Paraskevopoulos and Irwin,²² Hynes et al.,¹³ and McCabe et al.¹⁶ Water is not expected to significantly change the rate coefficient for the reaction in the atmosphere and it is not expected to alter the products of the reaction.

Troe²⁶ has carried out extensive theoretical analysis of this reaction system. Senosiain et al.²⁵ performed empirical master equation calculations on a theoretical potential energy surface (the temperature exponent of k_{∞} for the chemical activation pathway has a sign error in the reference). The recent *ab initio* calculations of Nguyen et al.¹⁸ (also see Weston et al.²⁷) fitted from 175–300 K predict $k_{\infty}(300) = 7.4 \times 10^{-13} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$, $n = -1.50$, which are in good agreement with the entries in Table 2.2. Recently, time-resolved frequency comb spectroscopy has been used to directly monitor the concentrations of all of the reactants, products, and intermediates in the reaction of deuterated hydroxyl radical (DO + CO).³⁻⁵ This enables determination of the branching ratio between the two reaction channels and the isomerization between the *cis*- and *trans*-DOCO products. Note, however, that the branching ratio between the two channels is not important in Earth's atmosphere because both H and HOCO react very rapidly with O₂ to form HO₂ + CO₂.

K4. $\text{C}_2\text{H}_5 + \text{O}_2$. Early direct mass spectrometric measurements of the title reaction were reported by Plumb and Ryan¹⁸ and by Slagle et al.²¹ at low pressures of He and by Munk et al.¹⁶ at 1 atm of H_2 . Plumb and Ryan and Munk et al. also reported branching fractions for the $\text{HO}_2 + \text{C}_2\text{H}_4$ reaction channel. Kaiser et al.¹⁰ measured the total reaction rate constant relative to that for $\text{C}_2\text{H}_5 + \text{Cl}_2$, (calibrated at low He pressures to agree with the absolute measurements of Slagle et al.²¹) in order to obtain absolute rate constants and fall-off parameters at 298 K in He: $k_\infty = (9.2 \pm 0.9) \times 10^{-12} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ and $k_0 = (6.5 \pm 2.0) \times 10^{-29} \text{ cm}^6 \text{ molecule}^{-2} \text{ s}^{-1}$. Kaiser et al.¹⁰ also measured the branching fraction to produce $\text{HO}_2 + \text{C}_2\text{H}_4$ at 298 K and N_2 pressures from 5 to 700 Torr. Later, Kaiser⁸ reported branching fractions and used the relative rate technique to measure total rate constants as a function of temperature and pressure in He and O_2 . Wagner et al.²³ performed measurements in He and carried out a detailed theoretical analysis of the reaction system. Dilger et al.⁴ used the muon spin relaxation technique to measure the total rate constant from 259–425 K at N_2 pressures from 1.5 to 60 bar and recommended $k_\infty = (8.7 \pm 0.8) \times 10^{-12} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ at 298 K; a least squares fit to their data gives a temperature exponent of $m = 1.7$. DeSain et al.³ investigated the HO_2 yield (branching fraction of the chemical activation channel) by LIF in a pulsed photolytic Cl-initiated experiment and carried out modeling studies. Fernandes et al.⁶ reported high pressure flash photolysis measurements in 100–1000 bar of Ar and 0.7–2 Torr of He and, after a theoretical analysis, recommended $k_\infty = (8.4 \pm 0.5) \times 10^{-12} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ at 298 K and a complicated temperature dependence. k_∞ has been calculated by Wagner et al.,²³ Miller and Klippenstein,¹⁵ Sheng et al.²⁰ and Knepp et al.¹² with $k_\infty(300 \text{ K}) = 8, 10, 4$ and $8 \times 10^{-12} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$, respectively. Although all studies cite some small temperature dependence, each study recommends neglecting it. A least squares fit of the prediction by Knepp et al.¹² gives a temperature exponent of $m = 1.3$.

For this evaluation, the relative measurements of Kaiser et al.⁹ and Kaiser,⁸ were re-computed using the more recent reference rate constant for $\text{C}_2\text{H}_5 + \text{Cl}_2$ from Eskola et al.⁵ and for the experiments buffered with helium, the He pressures were scaled by a factor of 0.38 to make them comparable to N_2 pressures.⁹ The recommendation is based on a least squares analysis of data for the total rate constant measured at $T \leq 425 \text{ K}$ by Kaiser et al.,⁹ Kaiser,⁸ Dilger et al.,⁴ and Fernandes et al.⁶ combined with data for the branching ratio that were measured at $T \leq 425 \text{ K}$ by Kaiser et al.,⁹ Kaiser,⁸ and Wagner et al.²³ The recommended parameters were obtained by performing a series of least squares analyses of the data for the total rate constant, while assuming fixed values for parameters A and B; the recommendation is an empirical compromise that gives a reasonable fit both to the total rate constant (average error ratio $f_{\text{total}}(298) = 1.15$) and to the branching ratio (average error factor $f_{\text{branch}}(298) = 1.8$). In order to account for errors associated with the relative rate measurement technique, the recommended error factor has been increased to $f(298) = 1.25$. The recommended high-pressure limit is in reasonable agreement with all of the experimental measurements and most of the theoretical studies. The recommended total rate constant is in good agreement the parameters reported by DeSain et al.³ and with studies reported by Selzer and Bayes,¹⁹ Pilling and Smith,¹⁷ Cobos et al.,² Laguna and Baughcum,¹³ Keiffer et al.,¹¹ Callear,²² Hochenadel et al.,⁷ Basco et al.,¹ Washida and Bayes,²⁵ Laufer and Bass,¹⁴ and Washida.²⁴ The branching ratio data are quite scattered and show systematic deviations, but the branching ratio is small under atmospheric conditions and the recommendation falls within about a factor of 2 of most of the data.

K5. $\text{CH}_3\text{C}(\text{O}) + \text{O}_2$. The recommendation is based on a least-squares analysis of the data obtained for N_2 bath gas by Papadimitriou et al.,¹² who measured rate constants at 241, 296, and 373 K by using three independent techniques: PLP-LIF of the OH product, PLP-CRDS of CH_3CO radical, and VLPR measurements of the total reaction rate relative to the rate of $\text{CH}_3\text{CO} + \text{Cl}_2$ (reference rate constant taken from Gierczak et al.⁵). Papadimitriou et al. analyzed their data with the chemical activation mechanism and critically compared their results for He bath gas with previous investigations that used He. Their total rate constants and yields of HO free radicals (first mentioned by Michael et al.¹¹) in He bath gas are in reasonable agreement with investigations by Talukdar et al.,¹⁵ McDade et al.,¹⁰ Kovacs et al.,⁸ Kaiser and Wallington,⁷ and Groß et al.⁶ Rate constants obtained by Tyndall et al.¹⁶ in a relative rate study (adjusted by using the more recent reference rate constant from Gierczak et al.⁵) in N_2/O_2 bath gases at 298 K are more scattered and ~15% lower than those of Papadimitriou et al.¹² The rate constant measured by Sehested et al.¹⁴ in 1 bar of SF_6 at 295 K ($(4.4 \pm 0.7) \times 10^{-12} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$) is in reasonable agreement with the recommended $k_\infty(298 \text{ K})$. Branching ratios determined at Leeds by Blitz et al.,^{1,2} Romero et al.,¹³ and Carr et al.^{3,4} are all self-consistent, but differ by a factor of ~3 from all other studies. Groß et al.⁶ noted that the Leeds experiments required significant correction factors and sensitive curve-fitting, which may have led to systematic errors. The $f(298 \text{ K})$ error factor is based on the fit to the N_2 bath gas data reported by Papadimitriou et al.¹² Theoretical master equation/RRKM simulations by Maranzana et al.⁹ demonstrated that the simulations can separately reproduce either the Leeds results, or those of Talukdar et al.¹⁵ and Kovacs et al.,⁸ depending on the empirical parameter that describes collisional energy transfer. Theoretical calculations by Carr et al.^{3,4} also confirmed that master equation calculations with empirical energy transfer parameters can fit the Leeds data.

K6. $\text{CH}_2\text{I} + \text{O}_2$. This reaction produces significant yields of thermalized formaldehyde oxide (CH_2OO), the simplest carbonyl oxide, which is also known as a Criegee Intermediate.¹ The recommendation for the total rate constant at 298 K is the average of measurements by Masaki et al.,¹¹ Eskola et al.,⁵ Sheps,¹² and Stone et al.¹³ The total rate constant displays very little pressure dependence from a few Torr up to at least 1 atm. The recommended parameter m is taken from fitting the data of Eskola et al.,⁵ who used a flow tube coupled to a photoionization mass spectrometer. The recommended parameters A and B are based on assuming that the $P = 0$ rate constant is equal to the recommended $k_\infty(T)$ as expressed in Arrhenius form. The recommended low pressure $k_0(298)$ and exponent n are based on the direct branching ratio measurements of Ting et al.¹⁴ and of Huang et al.¹⁰ obtained in N_2 , O_2 , and $\text{N}_2 + \text{O}_2$ mixtures. Yields of the $\text{CH}_2\text{OO} + \text{I}$ products in this reaction under one atmosphere of air near 300 K have been reported to be 0.15 ± 0.03 ,^{8,9} ~ 0.18 ,¹³ and ~ 0.35 .¹⁴ The only other major product is collisionally stabilized CH_2IO_2 free radical. Small yields ($\leq 20\%$) of IO free radicals have been reported at low pressures by Enami et al.,^{3,4} Dillon et al.,² Ting et al.,¹⁴ and Foreman and Murray.⁶ Gravestock et al.⁷ and Stone et al.¹³ have used several techniques to investigate the secondary reactions in this system. Foreman and Murray⁶ concluded that the IO yields are due in part to reactions of vibrationally excited CH_2I free radicals produced by photolysis of CH_2I_2 at shorter wavelengths, and contributions from secondary reactions. Ting et al.¹⁴ developed a detailed mechanism and concluded that yields of species other than CH_2OO and CH_2IO_2 are negligible at pressures ≥ 60 Torr. In the context of their detailed mechanism, Ting et al.¹⁴ and Huang et al.¹⁰ used time-resolved FTIR spectroscopy to investigate the yields of CH_2OO in N_2 , O_2 , and $\text{N}_2 + \text{O}_2$ mixtures; together, these studies covered the ranges of 295–343 K and $[\text{N}_2]$ from $2\text{--}16 \times 10^{18}$ molecules cm^{-3} . In addition, Huang et al.¹⁰ used direct detection of both CH_2OO and CH_2IO_2 to obtain improved results. The error factor $f(298)$ is based on fits to the total rate constants measured by Eskola et al.⁵ and the fractional yields of CH_2OO measured by Ting et al.¹⁴ and Huang et al.¹⁰

TABLE 3-1. EQUILIBRIUM CONSTANTS	3-3
--	-----

3.1 Format

Some three-body reactions form products that are thermally unstable at atmospheric temperatures. In such cases, the thermal decomposition reaction may compete with other loss processes, such as photodissociation or radical attack. Table 3-1 lists the equilibrium constants, $K_{eq}(T)$, for reactions that may fall in this category. Each reaction in Table 3-1 has six column entries, the first two being the parameters A and B that can be used to express $K_{eq}(T)$:

$$K_{eq}(T)/\text{cm}^3 \text{ molecule}^{-1} = A \exp(B/T) \quad (200 < T < 300 \text{ K})$$

The third column entry is the calculated value of $K_{eq}(298 \text{ K})$, while the fourth and fifth columns contain the estimated uncertain factors $f(298 \text{ K})$ and g , respectively (see Table 3-1 footnote for uncertainty calculation method). The data sources for $K_{eq}(T)$ are described in the individual notes to Table 3-1, with a hyperlink to the note given in column six.

3.2 Definitions

When values of the heats of formation and entropies of all species in an equilibrium reaction are known at temperature T , the equilibrium constant, $K_{eq}(T)$, is given by the van't Hoff equation:

$$\ln(K_{eq}(T)) = \frac{\Delta S_T^\circ}{R} - \frac{\Delta H_T^\circ}{RT}$$

where $K_{eq}(T)$ is in units of bar^{-1} and the superscript “o” refers to a standard state of one bar. For $K_{eq}(T)$ in units of $\text{cm}^3 \text{ molecule}^{-1}$:

$$\ln(K_{eq}(T)) = \frac{\Delta S_T^\circ}{R} - \frac{\Delta H_T^\circ}{RT} + \ln(T) - 50.37$$

When the entropy is known, or can be calculated from molecular properties, as a function of temperature, experimental values of $K_{eq}(T)$ can be used to extract a value for ΔH_0 enabling $K_{eq}(T)$ to be calculated over a wider temperature range (Third law method.). The parameters A ($\text{cm}^3 \text{ molecule}^{-1}$) and B (K) in Table 3-1 are determined from a linear fit of $\ln(K_{eq}(T))$ vs $1/T$. In some cases, $K_{eq}(T)$ was calculated directly from the forward and reverse reaction rate coefficients. When only thermochemical values at 298 K were available, they were treated as temperature independent and used to calculate $K_{eq}(200\text{--}300 \text{ K})$. The following equations were then used to calculate the parameters A and B :

$$B = \left(\frac{300 \times 200}{(300 - 200)} \right) \ln \left(\frac{K_{eq}^{200}}{K_{eq}^{300}} \right) = 600 \ln \left(\frac{K_{eq}^{200}}{K_{eq}^{300}} \right)$$

$$\ln(A) = \ln(K_{eq}^T) - \frac{B}{T}$$

The relationships between the parameters A and B and the quantities $\Delta S^\circ(298\text{ K})$ and $\Delta H^\circ(298\text{ K})$ are:

$$A = \frac{eR'T}{N_{\text{av}}} \exp\left(\frac{\Delta S_{298\text{ K}}^\circ}{R}\right) = 3.7 \times 10^{-22} T \exp\left(\frac{\Delta S_{298\text{ K}}^\circ}{R}\right)$$

where $R' = 83.145\text{ cm}^3\text{ bar mol}^{-1}\text{ K}^{-1}$, $N_{\text{av}} = 6.02 \times 10^{23}\text{ molecule mol}^{-1}$ and

$$B = -\left(\frac{\Delta H_{298\text{ K}}^\circ + RT}{R}\right)$$

Table 3-1. Equilibrium Constants

Reaction	A cm ³ molecule ⁻¹	B K	$K_{eq}(298\text{ K})$	$f(298\text{ K})^a$	g^a	Note

$K_{eq}(T) = A \exp(B/T)$ [200 < T/K < 300] in cm³ molecule⁻¹ units

Shaded areas indicate changes or additions since 19-5.

- a $f(298\text{ K})$ is the uncertainty factor at 298 K, and g is a measure of the uncertainty in the quantity B . To calculate the uncertainty at temperatures other than 298 K, use the expression:

$$f(T) = f(298\text{ K}) \exp \left[g \left(\frac{1}{T} - \frac{1}{298} \right) \right]$$

3.3

Notes to Table 3-1

1. **H₂O + H₂O ⇌ (H₂O)₂ (water dimer).** The recommendation is based on the optimized Active Thermochemical Tables of Ruscic,¹ which utilizes a comprehensive thermochemical network that includes all of the prior work related to this equilibrium. K_{eq} from Ruscic agrees very well with the recent work of Scribano et al.² and references cited therein. The error limit was set to encompass the exponential fit to the K_{eq} of Ruscic (which is not exactly exponential). For more accurate values, the following non-exponential fit falls within 2% of Ruscic's values:

$$K_{eq} = 1.92 \times 10^{-23} \exp[(1 + 43/T) \times 1216/T] \text{ cm}^3 \text{ molecule}^{-1}$$

(Table: 15-10; Note: 15-10; Evaluation 15-10) [Back to Table](#)

- (1) Ruscic, B. Active thermochemical tables: Water and water dimer. *J. Phys. Chem. A* **2013**, *117*, 11940-11953, doi:10.1021/jp403197t.
- (2) Scribano, Y.; Goldman, N.; Saykally, R. J.; Leforestier, C. Water dimers in the atmosphere III: Equilibrium constant from a flexible potential. *J. Phys. Chem. A* **2006**, *110*, 5411-5419, doi:10.1021/jp056759k.

2. **HO + NO₂ ⇌ HOONO.** The tabulated value is for the *cis,cis*-HOONO product channel (see below for formation of the *trans,perp*-HOONO isomer, which is unlikely to be important in the atmosphere). Using the data from Hippler et al.,⁴ Golden et al.^{2,3} performed a third law analysis using structures and frequencies from an ab initio quantum calculation to extract the heat of formation of *cis-cis*-HOONO ($\Delta H_f^\circ(0 \text{ K}) = -9.3 \text{ kJ mol}^{-1}$). The data covers the temperature range $430 < T/\text{K} < 475$ with 30% uncertainties. Most vibrational frequencies have been identified using matrix isolation spectroscopy¹⁰ and the moments of inertia have been measured by microwave spectroscopy.¹ High level CCSD(T) calculations and spectral simulation of overtone and action spectra have examined the torsion in considerable detail.⁹ Mathews and Sinha⁸ measured overtone action spectra and carried out an analysis that gave $D_0 = 83.3 \pm 2.1 \text{ kJ mol}^{-1}$. By using the observed frequencies (supplemented by the high level CCSD(T) calculations¹⁰), moments of inertia, and the potential energy and moment of inertia of the internal rotor,⁹ a new third law analysis using the data from Hippler et al.⁴ gives the entropy for reaction that differs from the previous analysis by $-5.6 \text{ J K}^{-1} \text{ mol}^{-1}$ and a new estimate of $D_0 = 81.5 \pm 0.8 \text{ kJ mol}^{-1}$ and $\Delta H_f^\circ(0 \text{ K}) = -7.6 \text{ kJ mol}^{-1}$ ($\Delta H_f^\circ(298 \text{ K}) = -14.9 \text{ kJ mol}^{-1}$ and $S_f^\circ(298) = 279 \text{ J K}^{-1} \text{ mol}^{-1}$).

For formation of the *trans,perp*-HOONO product channel (which is of negligible atmospheric importance), the reaction is written $\text{HO} + \text{NO}_2 \rightarrow \text{trans,perp-HOONO}$. Konen et al.^{5,6} used infrared overtone action spectroscopy in a molecular beam apparatus to determine $D_0 = 67.8 \pm 0.4 \text{ kJ mol}^{-1}$. High level CCSD(T) calculations⁵ supported by analysis⁷ of the action spectra give vibrational frequencies and moments of inertia. These data are used to calculate $\Delta H_f^\circ(0 \text{ K}) = 6.1 \text{ kJ mol}^{-1}$ ($\Delta H_f^\circ(298 \text{ K}) = -0.5 \text{ kJ mol}^{-1}$ and $S_f^\circ(298) = 291 \text{ J K}^{-1} \text{ mol}^{-1}$). Using these parameters, the equilibrium constant is given by $K_{eq}(\text{trans,perp}) = 1.33 \times 10^{-26} \exp(8390/T)$ with uncertainty factors set so that all of the data used for the recommendation fall within the 2σ error bounds.

3. **$\text{HO}_2 + \text{NO}_2 \rightleftharpoons \text{HO}_2\text{NO}_2$.** The value was obtained by combining the expression from Table 2-1 for the rate constant of the reaction as written with that from an average of the expressions from Graham et al.³ and Zabel⁴ for the reverse reaction. Values for the entropy and heat of formation of pernitric acid may be extracted. These values are: $S(298\text{ K}) = 71.7\text{ cal mol}^{-1}\text{ K}^{-1}$ and $\Delta H_f(298\text{ K}) = -12.9\text{ kcal mol}^{-1}$. If the entropy is calculated from the frequencies and moments of inertia given by Chen and Hamilton,¹ the value becomes 71.0 and the heat of formation is -13.1. The values in the Thermochemistry Section of this report reflect these results. A study of the thermal decomposition of HO_2NO_2 by Gierczak et al.² combined with values for the association reaction are in agreement.

4. **$\text{HO}_2 + \text{H}_2\text{O} \rightleftharpoons \text{HO}_2\cdot\text{H}_2\text{O}$.** The influence of water vapor on the $\text{HO}_2 + \text{HO}_2$ bimolecular rate constant was first shown by Hamilton,⁵ who invoked formation of a $\text{HO}_2\cdot\text{H}_2\text{O}$ complex with $\sim 38\text{ kJ mol}^{-1}$ binding energy. Since then, several other groups have quantified the effect on the $\text{HO}_2 + \text{HO}_2$ reaction (see Table 1). Only two direct measurements of the equilibrium constant have been carried out. Aloisio et al.¹ used FTIR absorption spectroscopy around 1120 cm^{-1} to measure the depletion of gas phase HO_2 as it formed a complex with H_2O . They measured K_{eq} at 230 and 250 K, and obtained only an upper limit at room temperature. Kanno et al.^{7,8} also monitored depletion of gas-phase HO_2 , but with high resolution FM spectroscopy of the HO_2 A-X transition near 7020 cm^{-1} with apparently higher sensitivity than in the FTIR measurement of Aloisio et al., since they could measure K_{eq} up to much higher temperatures ($250 \leq T \leq 350\text{ K}$). The two studies are in rough agreement on parameter *B*, but differ on parameter *A* by a factor of 7. Kanno et al.'s results are in very good agreement with the parameter *A* derived from quantum chemistry calculations by Aloisio et al.¹ The indirect estimate of K_{eq} by Cox and Burrows⁴ agrees better with Kanno et al., and the indirect estimate by Hamilton and Lii⁶ is in better agreement with Aloisio et al. The current recommendation for K_{eq} is based on Kanno et al.^{7,8} because their technique had higher sensitivity and because they measured K_{eq} over a much wider temperature range.
- A 3rd Law analysis of the Kanno et al. experimental data was carried out using the harmonic frequencies calculated by Aloisio et al.¹ (who used B3LYP/6-311++G(3df,3pd)) and the microwave rotational constants from Suma et al.¹⁰ This gives $S^\circ_{298}(\text{HO}_2\cdot\text{H}_2\text{O}) = 314.6\text{ J K}^{-1}\text{ mol}^{-1}$ and $D_0 = 34.2 \pm 1.2\text{ kJ mol}^{-1}$ (one sigma). Since the analysis is based only on the Kanno experiments, we adopt an estimated 95% confidence limit of $\pm 3\text{ kJ mol}^{-1}$. The results give $\Delta H_{f,0}(\text{HO}_2\cdot\text{H}_2\text{O}) = -259.6 \pm 3\text{ kJ mol}^{-1}$ and $\Delta H_{f,298}(\text{HO}_2\cdot\text{H}_2\text{O}) = -268.0 \pm 3\text{ kJ mol}^{-1}$. The values of $f(298\text{ K})$ and g were chosen to include the data of Aloisio et al.¹ Several additional theoretical studies^{2,3,9} have investigated complexes of $\text{HO}_2\cdot(\text{H}_2\text{O})_n$ ($n \geq 1$).

- 5. $\text{HO}_2 + \text{CH}_3\text{OH} \rightleftharpoons \text{HO}_2\cdot\text{CH}_3\text{OH}$.** The influence of CH_3OH on the $\text{HO}_2 + \text{HO}_2$ bimolecular rate constant was first shown by Andersson et al.,¹ who invoked formation of a $\text{HO}_2\cdot\text{CH}_3\text{OH}$ complex with $\sim 25 \text{ kJ mol}^{-1}$ binding energy to explain their results. Since then, several other groups have quantified the effect on the $\text{HO}_2 + \text{HO}_2$ reaction (see Table 1). The only direct measurement of the equilibrium constant was carried out by Christensen et al.² from 231 to 261 K. Their measurements are the basis for this recommendation. They obtained $\Delta_r H^\circ(246 \text{ K}) = -37.4 \pm 4.8 \text{ kJ mol}^{-1}$ and $\Delta_r S^\circ(246 \text{ K}) = -100 \pm 19 \text{ J K}^{-1} \text{ mol}^{-1}$. Christensen et al. also measured the forward and reverse rate constants and performed ab initio calculations, which are in reasonable agreement with the measured thermochemistry.

- 6. $\text{HO}_2 + \text{CH}_2\text{O} \rightleftharpoons \text{HOCH}_2\text{OO}$.** The recommendation is based on the data of Barnes et al.,² Burrows et al.,⁴ Veyret et al.,⁹ and Morajkar et al.⁷ All of these measurements, which are in good agreement with each other, relied on optical absorption to monitor the free radicals. The early measurement of Su et al.⁸ is considerably higher, for unknown reasons, as are the measurements of Zabel et al.,¹⁰ who utilized electron spin resonance to monitor the radical concentrations. The temperature dependence reported by Zabel et al. is in good agreement with the current recommendation, although the reported absolute magnitude of Zabel et al.'s K_{eq} is systematically about a factor of 6 or 7 greater. Theoretical work on this reaction has been reported by Evleth et al.,⁵ Aloisio and Francisco,¹ Benson,³ and Hermans et al.⁶

7. **HO₂ + CH₃CHO ⇌ CH₃CH(OH)OO.** Tomas et al.⁵ measured this equilibrium constant from 298 to 373 K by using flash photolysis with time resolved UV absorption spectroscopy to monitor all three species ($K_{eq} \approx 5.9 \times 10^{-17}$ cm³ molecule⁻¹ at 298 K). Moortgat et al.³ obtained product quantum yields from the photo-oxidation of CH₃CHO in air. In carrying out their data analysis, which involved a complicated chemical mechanism, they estimated $K_{eq} \approx 1 \times 10^{-17}$ cm³ molecule⁻¹ at 298 K. Morajkar et al.⁴ used laser flash photolysis with cavity ring-down spectroscopy (CRDS) at 297 K to monitor HO₂ radicals in real time; acetaldehyde concentrations were established by preparing gas mixtures (periodically checked in the cell by using laser induced fluorescence of OH and the known rate constant for OH + CH₃CHO). In their experiments, the HO₂ bi-exponential decays were used to extract $K_{eq} = (1.7 \pm 0.5) \times 10^{-17}$ cm³ molecule⁻¹ at 298 K without the necessity of measuring the concentration of CH₃CH(OH)OO directly. The recommendation is based on the value obtained by Morajkar et al.⁴ and the temperature dependence determined by Tomas et al.⁵ error bounds were set large enough to include almost all of the reported data. Theoretical calculations have been reported by Aloisia and Francisco¹ and by Hermans et al.²

8. **HO₂ + CH₃C(O)CH₃ ⇌ HO₂•CH₃C(O)CH₃.** The recommendation is based on the measured equilibrium constants that have been reported by Grieman et al.⁴ and Dillon et al.³ The two sets of data are in excellent agreement with each other. Both groups measured the HO₂ concentration with and without added acetone and identified the concentration difference with the concentration of the product (neither group observed the product adduct directly). Grieman et al. controlled the acetone concentration by temperature control of its vapor pressure and measured the HO₂ concentration by tunable IR diode laser absorption. Dillon et al used UV absorption to monitor the HO₂ and acetone concentrations. Both groups used information from theoretical calculations and other sources to determine that the product is the hydrogen bonded molecular complex (HBMC) and not the 2-hydroxyisopropylperoxyl radical isomer that is expected to be formed subsequently by a "tail-biting" cyclic hydrogen transfer reaction (analogous to the one that occurs in the reaction of HO₂ + CH₂O). Theoretical calculations at various levels of theory have been reported by Aloisia and Francisco,¹ Hermans et al.,⁶ Hermans et al.,⁵ Cours et al.,² and Dillon et al.³

9. **NO + NO₂ ⇌ N₂O₃.** The data are from JANAF² and Chao et al.¹ This process is included because a measurement of the rate constant by Smith and Yarwood⁴ and Markwalder et al.³ shows that it is too slow to be an important process in most atmospheric and laboratory systems.

11. $\text{NO}_2 + \text{NO}_3 \rightleftharpoons \text{N}_2\text{O}_5$. The recommendation is based on the direct measurements of K_{eq} reported by Cantrell et al.,⁴ Hjorth et al.,⁸ and Osthoff et al.¹¹ As pointed out by Osthoff et al., the differences among the direct measurements of K_{eq} differ mostly because of calibration errors in the absorption coefficients of NO_2 , N_2O_5 , and the NO_3 radical. The recommended parameters are based on the average of independent Third Law analyses of each experimental data set, carried out using the entropy of N_2O_5 computed by Alecu and Marshall.^{1,2} Alecu and Marshall^{1,2} employed a combination of M06-2X density functional theory and single point calculations at the CCSD(T)-F12a/cc-pVTZ-F12 level of theory, obtaining results in good general agreement with those computed by Glendening and Halpern.⁶ From their results, Alecu and Marshall computed the entropy of N_2O_5 by using the multi-structural method to account for the combination of the two internal torsions in the molecule, obtaining $\Delta S_f^0(298 \text{ K}) = 353.45 \text{ J K}^{-1} \text{ mol}^{-1}$.

The averaged Third Law analyses performed for this evaluation give $\Delta S_r^0 = -145.25 \text{ J K}^{-1} \text{ mol}^{-1}$ and $\Delta H_r^0 = -94.25 \text{ kJ mol}^{-1}$ at 298.15 K. These results are in excellent agreement with a similar analysis reported by Alecu and Marshall^{1,2} for the data of Osthoff et al. The current recommended values for K_{eq} are similar to a previous recommendation, which was based on the 'kinetics' K_{eq} reported by Cantrell et al.,⁴ who carried out a thorough review of previous literature. Cantrell et al. used only their own measured rate constants for the decomposition reaction and the rate constants reported by Orlando et al.¹⁰ for the recombination reaction to derive the 'kinetics' K_{eq} . The current recommendation is also in good agreement with the data of Burrows et al.³ and with the room temperature data of Tuazon et al.¹⁶ and of Perner et al.,¹² and with the exponential factor of Wängberg et al.¹⁸ (although their absolute values of K_{eq} differ significantly, probably due to an unidentified calibration error). It is also in good agreement with the evaluation by Pritchard,¹³ who reviewed the data of Cantrell et al.,⁴ Burrows et al.,³ Graham and Johnston,⁷ Wängberg et al.,¹⁸ Schott and Davidson,¹⁴ and the room temperature data of Tuazon et al.,¹⁶ Perner et al.,¹² and Hjorth et al.⁸ Pritchard also included the values given by Smith et al.,¹⁵ and Kircher et al.,⁹ who combined data on the forward reaction with decomposition data of Connell and Johnston⁵ and Viggiano et al.¹⁷

- 12. CH₃O₂ + NO₂ ⇌ CH₃O₂NO₂.** Zabel et al.⁴ have measured *k*(dissociation) as a function of pressure (10 < P < 800 Torr) and temperature (253 < T < 272 K). Bahta et al.¹ have measured *k*(dissociation) at 263 K. Using the values of *k*(recombination) suggested in this evaluation (Table-2), Golden³ has re-evaluated the equilibrium constant. Bridier et al.² measure an equilibrium constant in good agreement with this recommendation, reducing the uncertainty even further.

- 13. CH₃C(O)O₂ + NO₂ ⇌ CH₃C(O)O₂NO₂.** The recommendation is derived from measurements of the rate constants in both directions. The recombination (forward) rate constants measured directly by Bridier et al.¹ were fit by non-linear least squares, weighted by assuming uniform relative errors. Direct measurements of the forward reaction by Sehested et al.¹¹ at 298 K are in excellent agreement. Relative rate measurements by Cox et al.,⁴ Kirchner et al.,⁶ Tuazon et al.,¹² Seefeld et al.,¹⁰ and Sehested et al.¹¹ are confirmative. Measured rate constants for the reverse direction (unimolecular dissociation) taken from Bridier et al.¹ and from Sehested et al.¹¹ were used with the fitted expression for the forward rate constant to determine values for the “experimental” equilibrium constants, which were then used in a third law analysis. Data for the unimolecular decomposition reported by Roberts and Bertman⁹ and by Kabir et al.⁵ are in good agreement, but with larger scatter.
The third law analysis performed here employed vibrational frequencies for peroxyacetylnitrate reported by Coronel et al.³ and rotational constants calculated by von Ahse et al.¹³; the 1D hindered internal rotations of the CH₃ and NO₂ groups were treated explicitly. Parameters for acetyl radical were taken from Maranzana et al.⁷, and those for NO₂ were taken from the JANAF Tables.² The recommended expression for the equilibrium constant was obtained by fitting the third law values for *K*_{eq} from 180 to 300 K, and is in good agreement with the previous recommendation, but is based on more experimental data and higher level theoretical calculations. The estimated error limits were chosen so that most of the data used for the recommendation fall within the 2σ error bounds. The third law value of the reaction enthalpy is reproduced in a theoretical study by Miller et al.⁸ A theoretical study by Wei et al.¹⁴ is noted.

- 14. CH₃CH₂C(O)O₂ + NO₂ ⇌ CH₃CH₂C(O)O₂NO₂.** Assumed to be the same as for PAN. Both sides of the of the reaction differ from PAN by the group C-(C)(CO)(H)₂. Error limits are estimated and expanded from those for PAN.
(Table: 02-25, Note: 02-25, Evaluated: 02-25) [Back to Table](#)
- 15. CH₃C(O)CH₂ + O₂ ⇌ CH₃C(O)CH₂O₂.** Hassouna et al.¹ measured the rate constant and equilibrium constant for this reaction. The temperature range for the equilibrium measurements was 459 < T < 520 K. They extracted the entropy and enthalpy changes over this temperature range from a van't Hoff plot (Second Law). Values reported are ΔS = -143.0 ± 4.0 J mol⁻¹ K⁻¹ and ΔH = -105.0 ± 2.0 kJ mol⁻¹. The value in Table 3 is computed assuming that these thermochemical values are constant to 200 K. They also performed quantum calculations, which confirmed the enthalpy measurement. They suggest ΔH_{f,298}(CH₃C(O)CH₂) = -32.9 ± 2.0 kJ mol⁻¹.

- 16. F + O₂ ⇌ FOO.** Taken from Campuzano-Jost et al.¹ There is good agreement with data from Pagsberg et al.⁶ This corresponds to a value for ΔH_{f,298}(FOO) = 6.13 ± 0.5 kcal mol⁻¹. There are several modern theoretical computations^{2,3,5} of this value, ranging from 6 to 9 kcal mol⁻¹. Feller et al.⁴ compute 5.8 ± 0.3 kcal mol⁻¹.

 - (6) Pagsberg, P.; Ratajczak, E.; Sillesen, A.; Jodkowski, J. T. Spectrokinetic studies of the gas-phase equilibrium $F + O_2 \rightleftharpoons FO_2$ between 295 and 359 K. *Chem. Phys. Lett.* **1987**, *141*, 88-94, doi:10.1016/0009-2614(87)80097-0.
- 17. $Cl + O_2 \rightleftharpoons ClOO$.** The recommendation is based on Nicovich et al.,⁸ Mauldin et al.,⁶ Baer et al.,³ and Suma et al.¹¹ The experimental determinations of K_{eq} by Baer et al. and Nicovich et al. do not rely on knowing the absolute value of the absorption cross section, and that of Nicovich et al. and Suma et al.¹¹ rely on kinetic modeling to determine K_c . As a result, this analysis weights the study of Baer et al. more heavily than the others. A third law analysis was carried out using known thermochemistry for Cl and O₂ (Active Thermochemical Tables Version 1.122⁹) and entropy for ClOO was computed using the structure (determined by microwave spectroscopy) of Suma et al.¹⁰ and the full set of anharmonicities (X_{ij}) from the neon matrix study of Müller and Willner.⁷ Using vibrational frequencies from Müller and Willner results in $S^\circ_{298}(ClOO) = 66.02 \text{ cal mol}^{-1} \text{ K}^{-1}$. Using, instead, the harmonic vibrational frequencies from Abbott and Schaefer² and isotope shifts Abbott¹ (both from CCSDT(Q)/CBS calculations) leads to $S^\circ_{298}(ClOO) = 66.32 \text{ cal mol}^{-1} \text{ K}^{-1}$. Both lead to $D_0 = 4.6 \pm 0.2 \text{ kcal mol}^{-1}$ and $\Delta H^\circ_{f,298} K(ClOO) = 23.8 \pm 0.2 \text{ (2 s.d.) kcal mol}^{-1}$. The K_c recommendation is based on the average of the fits to these two third-law expressions. For comparison, the third law analysis of Suma et al. yielded $D_0 = 4.7 \pm 0.1 \text{ kcal mol}^{-1}$ using all experimentally reported values of K_{eq} , except those of Baer et al., while Nicovich et al. and Mauldin et al.⁶ reported similar values of D_0 (albeit with error bars of $0.5 \text{ kcal mol}^{-1}$). The recent high-level theoretical study by Abbot and Schaefer obtained $D_0 = 4.8 \text{ kcal mol}^{-1}$.² The Active Thermochemical Tables Version 1.122⁹ gives $D_0 = 3.8 \text{ kcal mol}^{-1}$, based largely on two theoretical papers by Karton et al.^{4,5} Most of the uncertainty in the recommended K_{eq} derives from the differences among the experimental determinations.

19. **ClO + O₂ $\rightleftharpoons$ ClO•O₂.** DeMore² reports $K_{eq} < 4 \times 10^{-18} \text{ cm}^3 \text{ molecule}^{-1}$ at 197 K. His temperature dependence of the equilibrium constant is estimated using $S^\circ_{298}(\text{ClO} \cdot \text{O}_2) = 73 \text{ cal mol}^{-1} \text{ K}^{-1}$ and $\Delta H^\circ_{298} < 7.7 \text{ kcal mol}^{-1}$. A higher value of K_{eq} has been proposed by Prasad,³ but it requires $S^\circ(\text{ClO} \cdot \text{O}_2)$ to be about $83 \text{ cal mol}^{-1} \text{ K}^{-1}$, which seems unreasonably high. Carter and Andrews¹ found no experimental evidence for ClO•O₂ in matrix experiments. Prasad and Lee⁴ discuss these issues and question the validity of the upper limit reported by DeMore.

20. **(a) ClO + ClO $\rightleftharpoons$ ClOOCi.** The values of the equilibrium constant and the thermochemical parameters are from a third-law calculation based on the data of Hume et al.¹³ (206 to 250 K) and Klobas and Wilmouth¹⁶ (230–299 K). A second-law analysis of the data of Hume et al. is highly consistent with the third-law results, as are the second-law and third-law analyses by Klobas and Wilmouth. Results from both papers are statistically much more precise than previous studies, and the results of Hume et al. extend to temperatures which are more relevant to the stratosphere. The recommended value of K_{eq} is within 1% of the previous recommendation. All the data from Hume et al. and Klobas and Wilmouth falls within 14% of the recommended values, but the error limits were chosen to incorporate most of the error bars in these two studies, and, importantly, the uncertainties in the absorption cross section of ClOOCi and ClO. The recommended K_{eq} is generally consistent with the data of Cox and Hayman⁸ and Nickolaisen et al.¹⁸ The entropy of ClOOCi ($302.9 \text{ J mol}^{-1} \text{ K}^{-1}$ at 298 K) was calculated from rotational constants measured by Birk et al.,³ four vibrational frequencies measured by Jacobs et al.,¹⁴ and two frequencies computed by Matus et al.¹⁷ The entropy values are in close agreement with those calculated by Zhu and Lin²³ (symmetry number corrected by Golden¹¹ to account for optical isomers) or by treatment of the torsion as a hindered rotor,² in which case the symmetry number correction is not required. From the third-law analysis, the ClOOCi heat of formation at 0 K and 298 K are $\Delta H^\circ_{f,0} = 133.3 \pm 1 \text{ kJ mol}^{-1}$ and $\Delta H^\circ_{f,298} = 130.1 \pm 1 \text{ kJ mol}^{-1}$, in good agreement with the analysis of Hume et al. A study of branching ratios of ClO + ClO channels in Cl₂/O₂/O₃ mixtures by Horowitz et al.¹² also finds the equilibrium constant in O₂ at 285 K to be in agreement with the recommendation. Values at single temperatures from Ellermann et al.⁹ and from Boakes et al.⁴ fall outside the 95% confidence limit. Broske and Zabel⁵ measured the reverse reaction at four temperatures between 245 and 260 K. They used the parameters for the forward reaction recommended in JPL 02-25 to suggest van't Hoff parameters of 5.09×10^{-26} and 7584. van't Hoff parameters suggested by Plenge et al.,¹⁹ who measured $\Delta H_{f,0}(\text{ClOOCi}) = 134.0 \pm 2.80 \text{ kJ mol}^{-1}$ by photoionization mass spectrometry and computed the entropy change for the reaction, are 1.92×10^{-27} and 8430. Ferracci and Rowley¹⁰ report values of K_{eq} between 250 and 313 K that also fall within the 95% confidence limits. Several studies have derived values of K_{eq} using atmospheric measurements in the nighttime polar stratosphere under conditions where ClO and ClOOCi should be in equilibrium. These are summarized here but are not used in the derivation of the recommended equilibrium constants. Avallone and Toohey¹ used $K_{eq} = 1.99 \times 10^{-30} \times T \times \exp(8854/T)$ derived from *in situ* aircraft experiments. The Avallone and Toohey¹ expression yields values that are quite close to those from the recommended expression. Atmospheric measurements from an airborne platform have also been used by von Hobe et al.²² to deduce K_{eq} parameters of 3.61×10^{-27} and 8167, resulting in values which lie close to the lower 95% confidence limit. A reanalysis by

Canty et al.⁶ of ER-2 data between 185 and 200 K, from Stimpfle et al.,²¹ is consistent with the recommended K_{eq} . Santee et al.²⁰ report measurements in the Arctic and Antarctic night by satellite based instruments, which are close to the current recommendation. The recent analysis by Kleinböhl et al.¹⁵ is also consistent with the current recommendation.

(Table 19-5, Note: 19-5, Evaluated: 19-5)

(b) ClO + ClO $\rightleftharpoons$ ClOClO. Zhu and Lin²³ used the G2 composite method to calculate the bond dissociation energy $D_0(\text{ClO-ClO}) = 49.8 \text{ kJ mol}^{-1}$. Matus et al.¹⁷ used the CCSD(T)/aug-cc-pV(5+d)Z method extrapolated to the complete basis set limit and found that ClOClO is less strongly bound than ClOOCl by 33.9 kJ mol^{-1} at 298 K (Matus et al. estimate their errors to be less than 4.2 kJ mol^{-1}). Combining this value from Matus et al. with $\Delta H_{f,298}(\text{ClOOCl}) = 130.1 \pm 1 \text{ kJ mol}^{-1}$ gives $\Delta H_{f,298}(\text{ClOClO}) = 164.0 \pm 5 \text{ kJ mol}^{-1}$ ($\Delta H_{f,0} = 166.5 \pm 5 \text{ kJ mol}^{-1}$) for ClOClO. The vibrational frequencies and moments of inertia calculated by Matus et al. are in good agreement with those of Zhu and Lin²³ and Chase⁷. The entropy of ClOClO was calculated using the harmonic frequencies from Matus et al.,¹⁷ anharmonicities computed by Maranzana (2007, unpublished), and rotational constants from Chase,⁷ giving $S^\circ_{298}(\text{ClOClO}) = 312.6 \text{ J K}^{-1} \text{ mol}^{-1}$. Thermodynamic data for ClO radicals were taken from Chase.⁷ The 1-sigma errors in $\Delta S_{r,298}$ and $\Delta H_{f,298}$ are estimated to be $6 \text{ J K}^{-1} \text{ mol}^{-1}$ and 6 kJ mol^{-1} , respectively. Using these parameters, the equilibrium constant is given by $K_{eq}(\text{ClOClO}) = 6.5 \times 10^{-27} \times \exp(4460/T)$ with uncertainty factors $f(298 \text{ K}) = 2$ and $g = 600$.

- 21. $\text{Cl} + \text{OCIO} \rightleftharpoons \text{ClClO}_2$.** Because of the high energy barriers calculated for other plausible pathways ($\text{ClO} + \text{ClO}$ or isomerization of ClOOCl and ClOCIO), this pathway seems to be the most relevant for formation and dissociation of ClClO_2 (chloryl chloride). Zhu and Lin⁹ and found energy barriers of $>19 \text{ kcal mol}^{-1}$ separating ClClO_2 from ClOOCl and ClOCIO ; they did not identify any low energy paths from $\text{ClO} + \text{ClO}$ to ClClO_2 . Neither Zhu and Lin nor Grant et al.² reported pathways connecting $\text{Cl} + \text{ClOO}$ to ClClO_2 . It is noteworthy that Bröske and Zabel¹ did not see any evidence for formation of ClClO_2 when they measured the gas phase thermolysis of ClOOCl , although they were able to measure ClClO_2 produced in wall reactions. Thus, it seems unlikely that the gas phase isomerization reactions are fast enough to be significant. Experiments in cryogenic matrices by Jacobs et al.⁴ and Müller and Willner⁸ support the theoretical prediction that $\text{Cl} + \text{OCIO}$ produces both ClClO_2 and ClOCIO . However, ClOCIO is not observed when the reaction is carried out in the gas phase.⁷ This is consistent with the fact that the equilibrium constant for ClOCIO formation is enormously smaller than that for formation of ClClO_2 : based on data from Matus et al.,⁶ $K_{\text{eq}}(T)$ very roughly equals $7.0 \times 10^{-26} \times \exp(6200/T)$, corresponding to 9×10^{-17} at 298 K. The recommended K_{eq} for formation of ClClO_2 is based on a thermodynamic calculation using the spectroscopic data and theoretical energies. The vibrational frequencies and moments of inertia are known,^{7,8} giving $S^\circ_{298}(\text{ClClO}_2) = 294.4 \text{ J K}^{-1} \text{ mol}^{-1}$. The heat of formation of ClClO_2 has not been measured, but it has been calculated many times (see Zhu and Lin⁹ for a summary of calculations up to 2003). We note high-level calculations by Horny et al.,³ and Lee et al.,⁵ but the best calculations appear to be those by Matus et al.⁶ and Grant et al.² These authors concluded that $\Delta H_{f,0}(\text{ClClO}_2)$ is $5.1 \text{ kcal mol}^{-1}$ below that of ClOOCl . Matus et al. estimate their relative errors to be less than $\pm 1 \text{ kcal mol}^{-1}$. Coupled with the recommended value of $133.3 \pm 1 \text{ kJ mol}^{-1}$ for ClOOCl (see Note 14a), this gives $\Delta H_{f,0}(\text{ClClO}_2) = 112.0 \text{ kJ mol}^{-1}$ and $\Delta H_{f,298} = 107.9 \text{ kJ mol}^{-1}$. The 1-sigma errors in $\Delta S_{f,298}$ and $\Delta H_{f,298}$ are estimated to be $6 \text{ J K}^{-1} \text{ mol}^{-1}$ and 5 kJ mol^{-1} , respectively.

- 22. $\text{ClO} + \text{OCIO} \rightleftharpoons \text{Cl}_2\text{O}_3$.** Data are from Burkholder et al.,² Hayman and Cox,⁵ and Green et al.⁴ The best van't Hoff fit to all the data yields the recommended parameters. The 95% error limits encompass all the data. A calculation of the entropy and heat capacity from the structure and frequencies of ClOCl(O)O reported by Zhu and Lin⁸ allows a "3rd Law" fit that gives $K_{\text{eq}}/\text{cm}^3 \text{ molecule}^{-1} = 1.6 \times 10^{-27} \exp(7155/T)$ for $232 < T/\text{K} < 298$. By including the hindered rotor potential explicitly,¹ a new "3rd Law" fit obtained by fitting the data of Burkholder et al.² and Hayman and Cox,⁵ including the lowest temperature point, gives the new recommendation: $S^\circ_{298}(\text{Cl}_2\text{O}_3) = 337.8 \text{ J K}^{-1} \text{ mol}^{-1}$ ($80.7 \text{ cal mol}^{-1} \text{ K}^{-1}$) and $\Delta H_{\text{f},0}(\text{Cl}_2\text{O}_3) = 143.9 \text{ kJ mol}^{-1}$ ($34.4 \text{ kcal mol}^{-1}$) and $\Delta H_{\text{f},298}(\text{Cl}_2\text{O}_3) = 138.9 \text{ kJ mol}^{-1}$ ($33.2 \text{ kcal mol}^{-1}$). This compares to calculated values of $\Delta H_{\text{f},0}(\text{Cl}_2\text{O}_3) = 32.3 \text{ kcal mol}^{-1}$ from Zhu and Lin⁸ and $32.9 \text{ kcal mol}^{-1}$ from Sicre and Cobos.⁷ Burkholder et al.² reported that treating the lowest vibration as a free internal rotation increases the entropy of ClOCl(O)O by almost $9 \text{ cal mol}^{-1} \text{ K}^{-1}$, but this value, repeated by Green et al.,⁴ is not correct. Clark and Francisco,³ who calculated structure and frequencies, concluded that $S^\circ_{298}(\text{Cl}_2\text{O}_3) = 78.5 \text{ cal mol}^{-1} \text{ K}^{-1}$, based on harmonic frequencies. Li et al.⁶ have also reported theoretical structure and frequencies in general agreement with Zhu and Lin⁸ and Clark and Francisco,³ but energetics that are quite different.

- 24. $\text{Br} + \text{CH}_2=\text{C}(\text{CH}_3)\text{CH}=\text{CH}_2$ (isoprene) $\rightleftharpoons$ Product.** In a comprehensive study of the forward and reverse rates of this reaction (using laser flash photolysis of CF_2Br_2 precursor and atomic resonance fluorescence detection of Br-atoms), Laine et al.¹ determined K_{eq} from 210 to 298 K. The adduct(s) produced in the reaction

are not known, but may consist of several isomers; calculations (G4 method) reported by Laine et al. show that the energetically most stable isomer is $\text{BrH}_2\text{CC}(\text{CH}_3)\text{CH}=\text{CH}_2$. Analysis of the data by 2nd Law and by 3rd Law methods produced results in good mutual agreement. Laine et al. averaged the 2nd Law and 3rd Law results to obtain $\Delta_r H^{298} = -67.5 \pm 6.6 \text{ kJ mol}^{-1}$, and $\Delta_r S^{298} = -93 \pm 16 \text{ J K}^{-1} \text{ mol}^{-1}$. The present recommendation is based on a 3rd Law analysis. The recommended error parameters are larger than the 40% 2 σ relative errors (including both statistical and systematic) estimated by Laine et al.; they are set so that all of the K_{eq} data fall within the 2 σ error limits and an extra margin was added because only one determination of K_{eq} has been reported for this reaction.

(Table: 15-10, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

- (1) Laine, P. L.; Sohn, Y. S.; Nicovich, J. M.; McKee, M. L.; Wine, P. H. Kinetics of elementary steps in the reactions of atomic bromine with isoprene and 1,3-butadiene under atmospheric conditions. *J. Phys. Chem. A* **2012**, *116*, 6341-6357, doi:10.1021/jp212127v.

25. **$\text{Br} + \text{CH}_2=\text{CHCH}=\text{CH}_2$ (1,3-butadiene) $\rightleftharpoons$ Product.** In a comprehensive study of the forward and reverse rate constants of this reaction (using laser flash photolysis of CF_2Br_2 precursor and atomic resonance fluorescence detection of Br-atoms), Laine et al.¹ determined K_{eq} from 227 to 298 K; they estimated the 2 σ relative error to be ~40%. The adduct(s) produced in the reaction were not measured directly, but calculations (G4 method) by Laine et al. predict that the adduct formed by addition of Br to the terminal carbon is favored thermodynamically. Analysis of the data by 2nd Law and by 3rd Law methods produced results in fair mutual agreement. Laine et al. averaged the 2nd Law and 3rd Law results to obtain $\Delta_r H^{298} = -64.5 \pm 8.5 \text{ kJ mol}^{-1}$ and $\Delta_r S^{298} = -94 \pm 20 \text{ J K}^{-1} \text{ mol}^{-1}$, which provide the basis for the current recommendation. The recommended error parameters are larger than the 40% 2 σ relative errors (including both statistical and systematic) estimated by Laine et al.; they are set so that all of the K_{eq} data of Laine et al. fall within the 2 σ error limits and an extra margin was added because only one determination of K_{eq} has been reported for this reaction.

26. **$\text{IO} + \text{NO}_2 \rightleftharpoons \text{IONO}_2$.** The parameters were computed based on a combination of experimental and theoretical data. The rovibrational parameters and electronic energy levels for IO radical and NO_2 were obtained from the NIST/JANAF tables;² rovibrational parameters for IONO_2 were obtained from Marshall.⁵ The IO- NO_2 bond dissociation energy (D_0) is relatively uncertain, but estimates are provided by several recent publications. Golden³ carried out RRKM/master equation calculations and concluded that D_0 is ~150 kJ mol^{-1} . Kaltsoyannis and Plane⁴ obtained 117.9 kJ mol^{-1} from quantum chemical calculations at the CCSD(T)/aug-cc-pVTZ // B3LYP/aug-cc-pVTZ level of theory. Saiz-Lopes et al.⁹ reported a rounded value of 118 kJ mol^{-1} in their recent review article. Marshall⁵ obtained 113.6 (± 3.1) kJ mol^{-1} from quantum chemical calculations at the CCSD(T)/aug-cc-pVTZ // CCSD(T)/aug-cc-pVTZ level of theory. The $K_{\text{eq}} = A \times \exp(B/T)$ parameters computed based on D_0 from Golden, from Kaltsoyannis and Plane, and from Marshall are $A = 5.02 \times 10^{-28}$ ($\pm \sim 10\%$) and $B = 18240, 14380, \text{ and } 13860$. The recommendation is based on the average of the latter two. The entropy of IONO_2 computed using this model is $S(298) = 320.95 \text{ J K}^{-1} \text{ mol}^{-1}$. In earlier work, Rayez and Destriau⁸ reported $D_0 = 134 \pm 13 \text{ kJ mol}^{-1}$, Allan and Plane¹ reported $D_0 = 94.9 \text{ kJ mol}^{-1}$ and Papayannis and Kosmas^{6,7} reported D_0 values from 131.4 to 137.6 kJ mol^{-1} .

- 28. OH + (CH₃)₂S ⇌ (CH₃)₂SOH.** This recommendation is based on the results of Hynes et al.³ and Barone et al.,¹ who used deuterated dimethyl sulfide (DMS-d₆), and Williams et al.,⁷ who used both DMS-d₆ and non-deuterated DMS-d₀, in studies of the rate constants for the reaction and found clear evidence for adduct formation. In each case, K_{eq} was obtained by analyzing the rate constant data, which showed double-exponential decays. Hynes et al.³ measured K_{eq} from 250–267 K and reported an adduct bond energy of 13.0 ± 3.3 kcal mol⁻¹ from a van't Hoff (2nd Law) analysis and a bond energy of 10.1 ± 1.1 kcal mol⁻¹ based on a 3rd Law analysis using the theoretical molecular parameters computed by McKee.⁴ Barone et al. measured K_{eq} from 217–240 K and reported bond energies of 10.2 and 10.7 ± 2.5 kcal mol⁻¹ from 2nd and 3rd Law calculations, respectively. Williams et al. analyzed only their K_{eq} data for OH + DMS-d₆ (240–245 K) and obtained bond strengths of 10.9 ± 1.0 kcal mol⁻¹ from a 2nd Law analysis and 10.5 kcal mol⁻¹ from a 3rd Law analysis based on their own MP2/6-31+G(2d,p) quantum chemical calculations (in good agreement with McKee.⁵ The present recommendation was obtained from a 3rd Law analysis of the data for OH + DMS-d₆ from all three DMD-d₆ studies combined with the data for OH + DMS-d₀ from Williams et al. The 61 data points covered the temperature range from 217–261 K. The 3rd Law analysis used the theoretical molecular parameters for DMS and HODMS computed by Williams et al.⁷ and the properties of the OH radical from the JANAF² Tables and Ruscic et al.⁶ to obtain the dissociation energy (without zero point energies) D_e = 55.5 ± 1.3 kJ mol⁻¹ (2σ). When the zero-point energy differences are taken into account, this gives dissociation energies D₀(HO-DMS-d₆) = 43.2 ± 1.3 kJ mol⁻¹ and D₀(HO-DMS-d₀) = 43.0 ± 1.3 kJ mol⁻¹ (2σ).

- 29. $\text{CH}_3 + \text{SO}_3 \rightleftharpoons \text{CH}_3\text{SO}_3$.** Because this equilibrium has never been investigated in laboratory experiments, the Panel makes no specific recommendation, but notes that $\Delta_f H_0$ and $\Delta_f H_{298}(\text{CH}_3\text{SO}_3)$ have been investigated in theoretical studies. The results depend on both the level of theory and the size of the basis set. Salta et al.³ commented that composite methods (e.g. G2, G3, and CBS-QB3) seem to be somewhat more reliable than single-point methods like B3LYP and CCSD(T)), because the composite methods employ both high-level theory and empirical corrections for various effects. Salta et al. prefer CBS-QB3 because it extrapolates high level theory to the complete basis set limit. Single point calculations for $\Delta_f H_{298}(\text{CH}_3\text{SO}_3)$ have been reported by Resende and Almeida² (-244 kJ/mol, UCCSD(T)/cc-pVTZ//MP2/6-31G(d)) and for $\Delta_f H_0(\text{CH}_3\text{SO}_3)$ by Salta et al.³ (-280 kJ/mol from G3 // MP2/6-311++G(d, p) and -291 kJ/mol from G3 // B3LYP/6-311++G(2d,2p)). Results for $\Delta_f H_0(\text{CH}_3\text{SO}_3)$ obtained using composite methods have been reported by Salta et al.³ (-315 kJ/mol from CBS-QB3) and Cao et al.¹ (-308 kJ/mol from G3XMP2// B3LYP/6-311+G(3df,2p)). At the same level of theory, Cao et al. found 63.54 kJ/mol for $\Delta_f H_0$ for $\text{CH}_3\text{SO}_3 \rightarrow \text{CH}_3 + \text{SO}_3$; they also found that the reaction has a small intrinsic energy barrier (~1 kJ/mol, including zero point energy); they report the total rate constant for dissociation is $k_{\text{uni}} = (1.4 \times 10^{12}) \times (T^{0.15}) \times \exp(-7831/T) \text{ s}^{-1}$. Zhu et al.⁴ reported values for $\Delta_f H_0$ for $\text{CH}_3\text{SO}_3 \rightarrow \text{CH}_3 + \text{SO}_3$ obtained using both a single point method (CCSD(T)/6-311++G(2df,2pd)) and a composite method (CBS-QB3): 59.8 and 78 kJ/mol, respectively. From the data supplied in their paper (we treated the torsion as a hindered rotor) and molecular data for CH_3 and SO_3 , we calculate that the corresponding values for $\Delta_f H_0(\text{CH}_3\text{SO}_3)$ are -303 and -318 kJ/mol, respectively. Evaluated in this way, their CBS-QB3 result is in reasonable agreement that of Salta et al. From $\Delta_f H_0 = 78 \text{ kJ/mol}$ and other molecular parameters reported by of Zhu et al.⁴ (and treating the torsion as a hindered internal rotor), $K_{\text{eq}}(T) = 9 \times 10^{-27} \exp(9550/T)$ and $S_{f,298}(\text{CH}_3\text{SO}_3) = 315 \text{ J K}^{-1} \text{ mol}^{-1}$. The uncertainty in $\Delta_f H_0$ is probably at least $\pm 10 \text{ kJ/mol}$, suggesting $f(298 \text{ K}) = 60$ and $g = 1200$. When the expression for $K_{\text{eq}}(T)$ is used with $k_{\text{rec},\infty}(T) = 2.2 \times 10^{-13} \times (T/298)^{-0.2} \text{ cm}^3 \text{ s}^{-1}$ (see Note in Table 2), the high pressure limit rate constant for unimolecular dissociation to $\text{CH}_3 + \text{SO}_3$ is $k_d^\infty = 2.1 \times 10^{+13} \times \exp(-9510/T \text{ s}^{-1})$ ($k_d^\infty(298) = 0.3 \text{ s}^{-1}$) with a combined uncertainty factor of $f(298 \text{ K}) = 600$.

- 33. CH₃S + O₂ ⇌ CH₃SOO.** Turnipseed et al.⁶ generated CH₃S radicals by pulsed laser photolysis of CH₃SCH₃ in an excess of O₂ and used LIF of CH₃S to monitor the subsequent reaction. Biexponential decays were observed, signaling the reversible formation of a weakly bound complex. The equilibrium constant was extracted in the data analysis over a range of temperatures from 216 to 258 K and a van't Hoff (2nd Law) analysis gives $K_{eq} = 7.9 \times 10^{-27} \exp(4978/T) \text{ cm}^3 \text{ molecule}^{-1}$. In a different experimental system, Butkovskaya and Barnes¹ (cited by Chu and Lee²) measured $K_{eq} = 1.4 \times 10^{-19}$ at 298 K, in good agreement with the 2nd Law expression given above for K_{eq} . The molecular properties of CH₃SOO have been computed in several theoretical studies^{4,5,7,8} and some vibrational transitions have been observed by FTIR.² The recommendation is based on a new 3rd Law analysis of the data of Turnipseed et al.⁶ This analysis made use of vibrational frequencies and rotational constants obtained from Chu and Lee² and from the NIST CCCBDB database.³ The value of K_{eq} (298 K) obtained by Butkovskaya and Barnes is in excellent agreement with the recommendation. The bond dissociation energies at 0 K and 298 K obtained in this 3rd Law analysis are 39.5 and 42.2 kJ mol⁻¹, respectively; the computed entropy of CH₃SOO at 298 K is 316.7 J K⁻¹ mol⁻¹.

- 34. Hg + Br ⇌ HgBr.** This equilibrium constant has never been measured directly. Goodsite et al.² used statistical rate theory combined with atomic and molecular properties to calculate the forward and reverse rate constants, from which K_{eq} can be obtained. Later, Goodsite et al.³ recomputed the rate constants with an updated HgBr bond dissociation energy (assumed to be 66.3 kJ mol⁻¹, which is the average of the spectroscopic determination by Tellinghuisen and Ashmore,⁶ the computed value (CCSD(T)) from Shepler et al.,⁵ and the JANAF value (from 1961). From the ratio of their forward and reverse rate constants we obtain $K_{eq} = 9.1 \times 10^{-24} \exp(7984/T)$. The spectroscopic determination of Tellinghuisen and Ashmore gives $D_0 = 5430 \pm 100 \text{ cm}^{-1}$ ($65.0 \pm 1.2 \text{ kJ mol}^{-1}$), where the estimated 1σ uncertainty arises from the extrapolation of the assigned vibrational levels to the dissociation limit. Dibble et al.¹ used this spectroscopic value in a direct statistical mechanics calculation, obtaining $K_{eq} = 9.1 \times 10^{-24} \exp(7801 \pm 201/T)$. Subsequent work by Jiao and Dibble⁴ suggests the electronic degeneracy, g_e , of HgBr is 2, rather than the value of 4 cited by Dibble et al.¹ The agreement between the two sets of A-factors noted above suggests that Goodsite et al. also used $g_e = 4$. The recommendation is based on this revision of the calculation of Dibble et al.¹ The uncertainty at 298 K is assumed to be a factor of 2 in the absence of directly measured values of K_{eq} , and the uncertainty in the temperature dependence arises largely from the uncertainty in the spectroscopic value of D_0 .³

4.1 Absorption Spectra and Uncertainty Estimates

Table 4-1 lists the molecules included in this evaluation that have ultraviolet (UV) and vacuum ultraviolet (VUV) absorption spectra considered to be of laboratory and atmospheric photochemical interest. The linked Notes for each molecule contain a summary of the available studies and the basis for the absorption cross section, $\sigma(\lambda, T)$, recommendation and estimated uncertainty. The ultraviolet (UV) absorption spectra of O₂ and O₃ largely determine the extent of the penetration of solar radiation into the stratosphere and troposphere. Some comments and references to these spectra are presented. For further detail see WMO Report No. 11;¹ WMO Report No. 16⁵ and the references cited in the Notes. The photodissociation of NO in the O₂ Schumann-Runge band spectral range is another important process requiring special treatment (see Frederick and Hudson,³ Allen and Frederick,² WMO Report No. 11,¹ and Minschwaner and Siskind⁴).

Some species included in this evaluation have highly structured spectra, e.g., SO₂. Notes are provided for these molecules, but complete photochemical data are not always presented. CH₂O, NO₂, NO₃, ClO, BrO, OClO, and SO₂ are examples of molecules that have complicated spectra, often resolution dependent UV/vis absorption spectra, but in view of their importance to atmospheric chemistry a sample of the data is presented in the evaluation. In these cases, detailed information on the high-resolution spectra and the temperature dependence of the spectrum should be obtained from the original cited literature.

Absorption cross sections are defined by the following expression of Beer's Law:

$$I = I_0 \exp(-\sigma(\lambda, T) n L)$$

where I_0 and I are the incident and transmitted light intensity, respectively, $\sigma(\lambda, T)$ is the absorption cross section in cm² molecule⁻¹ at wavelength λ and temperature T , n is the concentration in molecule cm⁻³, and L is the pathlength in cm.

Estimates of the uncertainty in $\sigma(\lambda, T)$ are provided within the Notes for many of the molecules included in this evaluation, but not all. The reported uncertainty factors are not rigorous values resulting from a detailed statistical error propagation analysis. Rather, they represent a consensus among the panel members as to the reliability of the data, taking into account the difficulty of the measurements and the agreement among the results reported by various groups. The uncertainty in $\sigma(\lambda, T)$ is, in most cases, expected to be wavelength and temperature dependent, e.g., the cross sections in wavelength regions with weak absorption or at low temperatures representative of the upper troposphere-lower stratosphere are usually more uncertain.

4.2 Photodissociation Thresholds and Quantum Yields

The threshold energies for the photolysis channels given in the Notes, and the corresponding wavelengths, were calculated using the 298 K heats of formation, $\Delta H_f(298 \text{ K})$ given in the Thermochemical Parameters section of this evaluation. Note that the threshold wavelengths do not account for possible photodissociation barriers.

The primary process in the photodissociation of chlorinated hydrocarbons is well established: absorption of ultraviolet radiation in the lowest frequency band is interpreted as an $n \rightarrow \sigma^*$ transition involving excitation to a repulsive electronic state (anti-bonding in C-Cl), which dissociates by breaking the carbon-chlorine bond (Majer and Simons¹). As expected, chlorofluoromethanes, which are a particular type of chlorinated hydrocarbons, behave in this fashion (Sandorfy²). The quantum yield for photodissociation is expected to be unity for these compounds. There are several studies that show specifically that this is the case for CF₂Cl₂, CFCl₃, and CCl₄. These studies also indicate that at shorter wavelengths two halogen atoms can be released simultaneously in the primary photolysis process.

The mechanism for the photodissociation of other classes of compounds, such as aldehydes and ketones, in many cases includes multiple product channels, where the different channels may have different impacts on atmospheric

chemistry. Photolysis quantum yields may also display a wavelength, pressure, and temperature dependence. Detailed quantum yield studies are presently not available for all molecules included in this evaluation. Quantum yield studies are cited and recommendations are made where possible.

SECTION 4A. O_x PHOTOCHEMISTRY

A1. O₂ (molecular Oxygen)

[Back to Index](#)

O ₂ + hν	→ O(³ P) + O(³ P)	494 kJ mol ⁻¹	242.3 nm	(1)
	→ O(³ P) + O(¹ D)	684 kJ mol ⁻¹	175 nm	(2)
	→ O(¹ D) + O(¹ D)	873 kJ mol ⁻¹	137 nm	(3)
	→ O(³ P) + O(¹ S)	906 kJ mol ⁻¹	132 nm	(4)
	→ O(¹ D) + O(¹ S)	1088 kJ mol ⁻¹	110 nm	(5)

(Recommendation: 10-6, Note: 15-10, Evaluated: 10-6)

Absorption Cross Sections: The photodissociation of molecular oxygen in the stratosphere is due primarily to the absorption of solar radiation in the 200–240 nm wavelength region, i.e., within the Herzberg continuum, which arises from the $A^3\Sigma_u^+ \leftarrow X^3\Sigma_g^-$ transition. Between 240 and 300 nm the absorption spectrum is also due to the electronic transition from the ground $X^3\Sigma_g^-$ state to excited electronic states $A^3\Sigma_u^+ \leftarrow X^3\Sigma_g^-$ (Herzberg I), $c^1\Sigma_u^- \leftarrow X^3\Sigma_g^-$ (Herzberg II), and $A'^3\Delta_u \leftarrow X^3\Sigma_g^-$ (Herzberg III). The 175–205 nm region, the O₂ Schumann-Runge ($B^3\Sigma_g^- \leftarrow X^3\Sigma_g^-$) band spectral range, is also very important, since solar radiation penetrates efficiently into the stratosphere at these wavelengths. The Schumann-Runge band system is composed of rotational lines with widths on the order of 1 cm⁻¹. The peak absorption cross sections in the Schumann-Runge system span ~5 orders of magnitude.

Table 4A-1-1. Summary of O₂ Absorption Cross Section Studies

Study	Year	Molecule ^a	Wavelength (nm)	Resolution (nm)	Temperature (K)
Preston ⁷⁰	1940	O ₂	121.567	0.01	298

^a Entries labeled “O₂” refer to molecular oxygen with natural isotopic abundance; studies of specific isotopes are labeled accordingly

^b Review: a status report on absorption cross section measurements

^c Refers to the low lying metastable state of O₂

^d J-calc-SR: a calculation of O₂ photodissociation coefficients in the Schumann-Runge bands

^e SR Atlas: a detailed compendium of line assignments of the Schumann-Runge bands

^f J-calc-HC: a calculation of O₂ photodissociation coefficients in the Herzberg Continuum

^g σ -calc-HC: a calculation of absorption cross sections in the Herzberg Continuum

^h σ -calc-SR: a calculation of absorption cross sections of the Schumann-Runge bands

Measurements of the absorption cross sections in the VUV have mainly been reported at low resolution during the period from 1952 to 1979 as listed in Table 4A-1-1. High resolution cross sections have been reported by Cole and Dexter,²³ Brion et al.,¹⁴ Gibson et al.,³⁰ Ahmed et al.,⁵ Wu et al.,⁸⁷ and Yoshino et al.¹⁰¹

At the Lyman- α wavelength (121.567 nm), absorption cross section values at 298 K were reported (in cm² molecule⁻¹) by Preston⁷⁰ (1.17×10^{-20}), Watanabe et al.⁸² (1.23×10^{-20}), Ogawa⁶⁴ (1.03×10^{-20}), Kley⁴⁴ (1.13×10^{-20}), and Lewis et al.⁵³ (9.1×10^{-21}). The latter authors measured the temperature dependence of the cross sections in the range 84–366 K. A value of $(1.1 \pm 0.1) \times 10^{-20}$ cm² molecule⁻¹ is recommended at 298 K. Kley⁴⁴ measured the pressure dependence of the Lyman- α cross section in the pressure range 20–880 Torr and in the temperature range 208–305 K. The cross sections were parameterized by the following equation: $\sigma_{O_2} = (1.13 \pm 0.09) \times 10^{-20} + (1.72 \pm 0.21) \times 10^{-23} \times P$ where P is the pressure in Torr.

In the Herzberg continuum (200–240 nm) Frederick and Mentall,²⁹ Herman and Mentall,³⁴ Anderson and Hall,^{7,8} and Pirre et al.^{68,69} estimated O₂ absorption cross sections from balloon measurements of solar irradiance in the stratosphere. These authors found the cross sections in the 200–210 nm range to be ~35% smaller than the smallest of the older laboratory results, which are those of Ditchburn and Young,²⁷ Hasson and Nichols,³³ Ogawa,⁶⁵ Shardanand,⁷⁴ and Shardanand and Prasad Rao.⁷⁵ The more recent laboratory studies (Johnston et al.,⁴² Cheung et al.,¹⁸⁻²⁰ and Jenouvrier et al.^{40,41}) confirm the lower values obtained from solar irradiance measurements. The recommended absorption cross section values between 205 and 240 nm are based on the data of Cheung et al.²⁰ and Jenouvrier et al.⁴⁰ and were evaluated by Yoshino et al.⁸⁸ as listed in Table 4A-1-2. The recommended values from 241–245 nm are from Fally et al.²⁸ (see below). Amoruso et al.⁶ have also carried out cross section measurements in the wavelength range 208–240 nm of the Herzberg continuum; their values are ~15% lower than those reported by Yoshino et al.⁸⁸ Coquart et al.²⁶ have reported Herzberg continuum absorption cross sections at 219 K in the wavelength region 196–205 nm of the S-R bands, in agreement with the determinations of Cheung et al.^{18,20} and Ogawa⁶⁵ and in line with the data of Yoshino et al.⁸⁸ Calculations of the absorption continua in the range 195–300 nm were performed by Saxon and Slanger.⁷³ Cross sections at elevated temperatures (up to 1073 K) and pressures (up to 6 bar) were reported by Vattulainen et al.⁷⁹

Table 4A-1-2. Recommended Absorption Cross Sections of O₂ between 205 and 245 nm

λ (nm)	$10^{24} \sigma$ (cm ² molecule ⁻¹)	λ (nm)	$10^{24} \sigma$ (cm ² molecule ⁻¹)
205	7.35	226	3.21
206	7.13	227	2.98
207	7.05	228	2.77
208	6.86	229	2.63

220	4.46	241	0.88
221	4.26	242	0.81
222	4.09	243	0.39
223	3.89	244	0.13
224	3.67	245	0.05
225	3.45		

Note:

205–240 nm: Yoshino et al.⁸⁸

241–245 nm: Fally et al.²⁸

The penetration of solar radiation in the atmosphere in the Schumann-Runge wavelength region was based originally on laboratory cross section measurements using insufficient spectral resolution. Yoshino et al.⁹⁸ reported high resolution O₂ cross section measurements and band oscillator strengths of the (1,0)–(12,0) S-R bands in the wavelength range 179–202 nm at 300 K, obtaining the first set of results that were not limited by the instrument lineshape. Additional studies at other temperatures, wavelengths, and isotopic compositions have been carried out by Yoshino et al.,^{90,94-97} Lewis et al.,^{51,52} Cheung et al.,^{16,17} and Chiu et al.²¹ More recently, Yoshino et al.⁸⁹ reported cross sections of the S-R bands in the window region between the rotational lines for wavelengths between 180 and 195 nm; these measurements supersede the their earlier values reported in Yoshino et al.⁹⁸

Absorption cross sections of the S-R continuum (130–175 nm) at room temperature were measured by Watanabe et al.,⁸³ Metzger and Cook,⁵⁶ and Ogawa and Ogawa.⁶⁶ Measurements of the temperature dependence were reported by Gibson et al.,³⁰ Hudson et al.,³⁵ Wang et al.,⁸¹ Kanik et al.,⁴³ and Yoshino et al.¹⁰¹

Minschwaner et al.⁵⁷ have fit temperature dependent (130<T<500 K) O₂ cross sections between 175 and 204 nm with polynomial expressions, providing an accurate model of the Schumann-Runge band cross sections that incorporates the most recent laboratory data. Detailed photodissociation rates for the Herzberg continuum $\lambda > 200$ nm were calculated by Nicolet and Kennes.⁶¹ A parameterization in the Herzberg continuum was reported by Nicolet and Kennes.⁶²

For parameterizations of the O₂ absorption in the Schumann-Runge bands used in atmospheric modeling calculations see Kockarts⁴⁵ and the review in WMO Report No. 16.⁸⁶ More recent work by Murtagh,⁵⁹ Nicolet and Kennes,⁶³ and Minschwaner et al.⁵⁷ incorporates results of the later laboratory measurements into efficient schemes for computing broadband transmission and photolysis rates. Transmission values obtained by Murtagh⁵⁹ agree well with the WMO⁸⁶ recommendations, although the high resolution calculations of Minschwaner et al.⁵⁸ differ with the WMO values by as much as 10–20% at some wavelengths.

Absorption cross section measurements in the region 240–300 nm were performed by Fally et al.²⁸ The different components of the spectrum, namely the discrete bands of the three Herzberg systems I, II, III (A, c, A' ← X), the Herzberg continuum, and the collision-induced Wulf bands were reported separately. The Herzberg continuum cross sections at 240 nm are in good agreement with the values reported by Yoshino et al.⁸⁸ and Jenouvrier et al.⁴⁰ The absorption cross sections measured by Fally et al.²⁸ in the range 241–245 nm

are entered in Table 4A-1-2. The absorption cross sections reported by Bogumil et al.¹³ are roughly five times larger (at 241 nm) than those reported by Fally et al.²⁸ High resolution studies were performed by Yoshino et al.,^{91,99,100} Huestis et al.,³⁷ Bao et al.,⁹ and Slanger et al.⁷⁶ in the 242 to 248 nm range, where weak absorptions cross sections were reported for some vibrational bands in the Herzberg systems.

The O₂ cross section uncertainty factor is estimated to be 1.2 (1 σ) for both the Schumann-Runge bands and continuum regions of its spectrum.

Photolysis Quantum yields and Product studies: The overall quantum yield for photodissociation channel (1), O(³P) + O(³P), is unity, $\Phi(1) = 1$, for $175 < \lambda < 242$ nm. Above the threshold for channel (2), O(³P) + O(¹D), at 175 nm, Lee et al.⁴⁷ and Nee and Lee⁶⁰ determined the quantum yield of O(¹D) to be unity. Thus, $\Phi(2) = 1$, in the wavelength range 139–175 nm. At 157 nm, both product channels (1) and (2) have been observed by Lin et al.,⁵⁴ with a relative yield for channel (1) of 0.55 ± 0.05 . At wavelengths shorter than 139 nm Lee et al.⁴⁷ observed strong variations in $\Phi(\text{O}^1\text{D})$, which was confirmed by Nee and Lee⁶⁰ (116–139 nm), Lee and Nee⁴⁹ (113–130 nm), and Lee and Nee⁵⁰ (105–113 nm). Lee et al.⁴⁷ reported $\Phi(\text{O}^1\text{D}) = \Phi(2) = 0.44 \pm 0.05$ at the Lyman- α line (121.567 nm). Lacoursière et al.⁴⁶ determined the O(¹D) yield across the entire Lyman- α profile from 121.2 to 121.9 nm at a spectral resolution of 0.0012 nm, and found $\Phi(\text{O}^1\text{D})$ to be strongly wavelength dependent in this window. $\Phi(\text{O}^1\text{D})$ varied from 1.0 at 121.35 nm through a minimum of 0.48 near 121.62 nm. A strong temperature dependence was found by Lewis et al.⁵³ with a minimum yield of 0.28 near 121.62 nm at 84 K.

(Recommendation: 10-6, Note: 15-10, Evaluated: 10-6)

Absorption Cross Sections. The O₃ absorption cross sections in the 200–790 nm region can be separated into four systems: the Hartley band (200–300 nm), the Huggins bands (300–370 nm), the Chappuis band (370–790 nm), and the Wulf bands extending towards longer wavelengths. The Hartley band is the strongest band and peaks around 255 nm. Although its overall shape is very smooth, there is residual vibrational structure in the region 250–260 nm. The Huggins band consists of a series of individual peaks and is marked with a drastic change of absorption cross sections (over more than five orders of magnitude) and strong temperature dependence. The Chappuis band is composed of a vibrational band progression superimposed on a continuous absorption in the visible region and is about a thousand times weaker than the Hartley band. The very weak near infrared part of the Chappuis band is clearly structured and corresponds to a different electronic transition (called the “Wulf bands”).

Photolysis of ozone in the Hartley system occurs predominantly via the two spin-allowed channels (1) and (5) (Ball et al.¹¹) whereas channels (2), (3) and (4) are spin forbidden. Channels (2) and (4) have been identified from photolysis in the Huggins band (Silvente et al.⁶⁴ and Denzer et al.³⁰).

For the three main bands in the 200–790 nm region, there have been many different measurements of the absorption spectrum and cross sections at various experimental (temperature and pressure) and instrumental conditions (resolution) during the last century as given in Table 4A-2-1. The available measurements can be organized into three groups: (A) measurements of absolute cross sections at single wavelengths (e.g. at the Hg resonance line at 253.65 nm), (B) measurements of absolute cross sections over broad spectral regions (typically covering a few hundred nm), (C) measurements of relative O₃ absorption spectra over broad spectral regions that have been scaled to absolute spectra using results from other studies (Type A or B), (D) measurements of the O₃ cross section at a single wavelength relative to the O₃ cross section at another wavelength.

Earlier reviews of the measured absorption cross sections were presented by Inn and Tanaka,⁴² Ackermann,¹ Hudson,⁴⁰ Nicolet,⁵⁵ Brion et al.,²¹ Steinfeld et al.,⁶⁷ Bacis et al.,⁹ Matsumi and Kawasaki,⁴⁹ and the WMO

Report No. 16,⁸³ which was the basis for the NASA/JPL 97-4 evaluation. Orphal^{59,60} has recently critically reviewed the available laboratory measurements up to 2003, and the NASA/JPL 10-6 evaluation is partly based on that review. Relevant for that evaluation are the measurements of type B and C, particularly those studies whose data were digitally available (marked with an asterisk*). Unfortunately, the recommended data set for the NASA/JPL 97-4 evaluation of Molina and Molina⁵³ was not considered in his review.

In the Hartley and Huggins bands (about 240–325 nm) there is generally very good agreement (better than 2–3%) between the data measured at room temperature (293–300 K) by Bass and Paur¹³ and Paur and Bass,⁶¹ Molina and Molina,⁵³ Freeman et al.,³³ Yoshino et al.,⁸⁵ the Reims-team (Daumont et al.,²⁶ Brion et al.,¹⁸ Malicet et al.,⁴⁶ and Brion et al.¹⁷), Yoshino et al.,⁸⁴ the Bremen-team (Burrows et al.,²⁴ Voigt et al.,⁸² and Bogumil et al.,¹⁶ Gorshchev et al.³⁶), Petersen et al.,⁶² and Viallon et al.⁷⁸ The older data by Ny and Choong,⁵⁷ Inn and Tanaka,⁴¹ and Vigroux⁷⁹ are about 8% greater than the data of Molina and Molina.⁵³ The vibrational structure between 240 and 270 nm was observed in most studies, except those of Inn and Tanaka,⁴¹ DeMore and Raper,²⁹ Davenport,²⁸ and Astholz et al.,⁷ who used lower resolution instruments.

Measurements of absorption cross sections in the shorter wavelength VUV region were performed by Tanaka et al.,⁷⁴ Ogawa and Cook,⁵⁸ and Mason et al.⁴⁷ At the Lyman- α wavelength, 121.567 nm, an absorption cross section of 2.32×10^{-17} cm² molecule⁻¹ was cited in the review by Ackermann.¹ Ogawa and Cook⁵⁸ measured 2.28×10^{-17} cm² molecule⁻¹ whereas Mason et al.⁴⁷ reported 2.99×10^{-17} cm² molecule⁻¹. The latter more recent value is recommended and entered in Table 4A-2-2.

A comparison of the O₃ cross-sections at the Hg-line wavelength 253.7 nm was performed by Orphal^{59,60} involving 13 absolute measurements and provided a mean value of $(114.1 \pm 0.9) \times 10^{-19}$ cm² molecule⁻¹. Viallon et al.⁷⁸ has since reported a cross section value of $(112.7 \pm 0.97) \times 10^{-19}$ cm² molecule⁻¹. The temperature dependence of the cross sections at 253.7 nm has been measured by Barnes and Mauersberger¹² between 195 and 351 K and by Malicet et al.⁴⁵ at 229 and 295 K. It has to be noted that the data of Bass and Paur¹³ and Paur and Bass⁶¹ are normalized to the absolute value 114.7×10^{-19} cm² molecule⁻¹ at 253.7 nm and 295 K measured by Hearn.³⁹ In the range 230–260 nm, the data of the Reims-team (Daumont-Brion-Malicet-Brion) are generally lower (up to 2.5%) than the data of Molina and Molina,⁵³ Bass and Paur,¹³ and the Bremen-team (Burrows-Voigt-Bogumil-Gorshchev-Serdyuchenko). Furthermore, the data of Voigt et al.⁸² show a strong baseline shift below 255 nm and in the range 310–320 nm; in addition, the spectra are very noisy in the Hartley band maximum. The data of Bogumil et al.¹⁵ contain periodic artifacts on the order of 0.5–1.0% in the range 240–270 nm and a stray light feature around 305 nm on the order of 2%.

Below 225 nm the room temperature cross sections of Molina and Molina,⁵³ DeMore and Raper,²⁹ and the Reims-team (Daumont-Brion-Malicet) agree within 1–2%, but are 2–5% larger than the measurements of Yoshino et al.⁸⁴ Other reported values measured by Ny and Choong,⁵⁷ Inn and Tanaka,⁴¹ Astholz et al.,⁷ and Griggs³⁷ differ up to 15%.

In the Huggins bands (310–350 nm) the studies differ in spectral resolution, which is mostly relevant only to atmospheric remote sensing. At wavelengths larger than 310 nm the vibrational structure becomes pronounced. In the range 310–340 nm, the agreement between the different studies is rather good (about 2%) for the data of Bass and Paur,¹³ the Reims-team (Daumont-Brion-Malicet-Brion), Burrows et al.,²⁴ Gorshchev et al.,³⁶ and Serdyuchenko et al.,⁶³ although important differences (up to 13%) due to wavelength shifts and spectral resolution are reported by Orphal.^{59,60} The data of Bass and Paur¹³ and of the Reims-team (Daumont-Brion-Malicet-Brion) show wavelength shifts of more than 0.02 nm. The data of Voigt et al.⁸² and Bogumil et al.¹⁶ contain systematic baseline drifts. Above 312 nm, the data of Molina and Molina,⁵³ which are listed every 0.5 nm up to 350 nm, occasionally miss the maxima and minima of the peaks. The reported values by Cacciani et al.²⁵ are typically 5–8% lower than the values of Molina and Molina⁵³ in the range 339–355 nm.

The O₃ absorption cross sections in the 350–450 nm region between the Huggins and Chappuis bands are very small and the available measurements of absolute values scatter significantly. They have been measured by Brion et al.,¹⁷ the Bremen team (Burrows-Voigt-Bogumil-Gorshchev-Serdyuchenko), Fuchs et al. (at 404 nm),³⁵ and Axson et al.⁸ At the minimum near 378 nm, the reported absolute cross sections at 298 K vary between 5×10^{-23} cm² molecule⁻¹ from Voigt et al.⁸² and 5×10^{-24} cm² molecule⁻¹ from Brion et al.¹⁷

Absorption cross section measurements of the Chappuis band of O₃ in the wavelength range 450–750 nm have been reported by Burkholder and Talukdar,²³ Brion et al.,¹⁷ the Bremen team (Burrows-Voigt-Bogumil-Gorshchev-Serdyuchenko), El Helou et al.,³¹ and at single wavelengths by Hearn,³⁹ Anderson and Mauersberger,⁵ Anderson et al.,⁴ and Enami et al.³² At the peak of the Chappuis band near 602 nm, the values agree within a few percent, although the data of the Bremen-team (Burrows-Voigt-Bogumil) are consistently larger than those of Brion et al.¹⁷ (by 2%) and Burkholder and Talukdar²³ (by 4%) (the latter data are scaled using the measurements of Anderson and Mauersberger⁵). Note that there are pronounced deviations of data

from Burkholder and Talukdar²³ in the region 425–490 nm. The older values of Vassy and Vassy,⁷⁷ Vigroux,⁷⁹ Inn and Tanaka,⁴¹ Griggs,³⁷ and Amoruso et al.³ deviate up to 20%.

Absorption cross sections in the Wulf band region (wavelength >750 nm) have been reported by Anderson et al.,⁴ Burkholder and Talukdar,²³ the Bremen-team (Burrows-Voigt-Bogumil-Gorshelev-Serdyuchenko), Enami et al.,³² and El Helou et al.³¹ The data measured at room temperature by the latter group are in excellent agreement (within 0.25%) with those of Anderson et al.⁴

The temperature dependence of the O₃ cross sections has also been studied by several of the groups mentioned above and tabulated in Table 4A-2-1. In the critical review, Orphal^{59,60} calculated and compared the integrated cross sections for 5 temperatures in the range 203–295 K in the different spectral regions of the O₃ spectrum. At all temperatures the agreement of the integrated cross sections in the Hartley band is better than 2% and less good agreement in the Chappuis band (4%). In particular, the integrated cross sections of Burkholder and Talukdar²³ lie systematically below the other measurements by about 3% and the data of Burrows et al.²⁴ are always higher by 2%. In the Huggins bands and the blue tail of the Chappuis band the integrated cross sections scatter by several percent (up to 5%), indicating systematic differences between the available data. The Hartley band integrated cross sections remain constant in the temperature range 203–293 K within the experimental uncertainties. The integrated cross sections in the Huggins bands decrease by more than 30% between 298 K and 203 K and the differential cross sections of the bands increase significantly.

In the Hartley band most studies report a slight (0.9–1.6%) increase of the cross section below 260 nm between room temperature and low temperatures 202–298 K, while Yoshino et al.⁸⁴ concluded that the temperature effect is negligible. Above 260 nm the cross section decreases significantly at lower temperatures. This effect is due to the changing populations of the various vibrational and rotational quantum states of ozone and has been analyzed by Simons et al.⁶⁵ The cross section values are not linearly proportional to the temperature; instead the effect is larger at the maxima than it is at the minima of the spectral features.

The absorption cross sections in the Huggins bands (310–350 nm) of O₃ decrease strongly with decreasing temperatures. Additionally, they depend on instrumental line shape and differences in wavelength calibration so that discrepancies up to 20% at the lowest temperatures are observed between the various studies. Comparison of the spectra obtained in the temperature range 220–229 K show good agreement (~3% at 325 nm, ~5% at 340 nm) with the data of Bass and Paur,¹³ Molina and Molina,⁵³ the Brion team (Daumont-Brion-Malicot-Brion), and Burrows et al.²⁴ The data of Voigt et al.⁸² and Bogumil et al.¹⁶ display sudden baseline jumps and are consistently lower than the other cited data sets. Voigt et al.⁸² observed in the region 335–380 nm the presence of “hot bands”, which disappear with decreasing temperature, and “cold bands”, which become more pronounced at lower temperatures.

In the Chappuis band, the available cross sections agree in showing a very small increase (1%) with decreasing temperature in the wavelength range 550–560 nm. However there is strong disagreement in the relative temperature dependence of the cross sections in the wings (400–550 nm and 650–790 nm) of the Chappuis band. Burkholder and Talukdar²³ report a decrease from 4% at 520 nm to 40% at 420 nm between 298 and 220 K, while Burrows et al.²⁴ observe a decrease at 420 nm to 70% at 221 K, and Bogumil et al.¹⁶ a decrease of 20% at 223 K. These discrepancies could be due to baseline problems in the different measurements. It was also noted by the Bremen-team (Burrows-Voigt-Bogumil-Serdyuchenko) that in the wings the differential cross sections increase up to 10% between 298 and 203 K. In addition, the band structures between 400 and 500 nm shift toward shorter wavelengths with decreasing temperature. El Helou et al.³¹ found the cross sections of the Wulf bands to be highly temperature dependent, increasing up to 91% upon reducing the temperature to 150 K.

Three different models have been proposed to reproduce the temperature dependence of the O₃ cross sections in the entire ultraviolet and visible regions within the experimental uncertainties. The first model was developed for the Hartley band by Adler-Golden² and uses an exponential function. The second model, developed by Bass and Paur,¹³ uses a quadratic polynomial to be applied in the Hartley and Huggins bands. The third model of Voigt et al.⁸² uses a double exponential function. The accuracy of the models was checked by Orphal,^{59,60} who concluded that the experimental data are better reproduced using a quadratic polynomial.

The pressure dependence of the O₃ absorption cross sections was investigated by Hearn³⁹ in the Hartley band and by Voigt et al.⁸² in the entire spectral region 240–790 nm. Both groups did not find experimental or theoretical support for pressure dependence, although Voigt et al.⁸² proposed that temperature variations of the cross sections around 400 nm might be due to the formation of a weakly bound O₂-O₃ complex.

The recommended absorption cross sections are listed in Table 4A-2-2, averaged over atmospheric intervals at 218 K and at room temperature (293–298 K). It has to be noted that cross sections are listed over 500 cm⁻¹ intervals in the region 185–300 nm, over 1 nm intervals in the region 300–321 nm, over 2 nm intervals in the

region 321.5–326.5 nm, and over 5 nm intervals in the region 330–825 nm. The 218 K values measured by the Reims-team (Daumont-Brion-Malicet-Brion) are only listed for the range 196–340 nm. The room temperature data were selected for the range 185–233 nm from the data of Molina and Molina,⁵³ for the range 323–310 nm from Burrows et al.,²⁴ and for the range 310–825 nm from the Reims team (Daumont-Brion-Malicet-Brion).

The uncertainty factor for the room temperature O₃ cross section is estimated to be 1.02 (1σ) near the peaks of the Hartley and Chappuis bands and the strong Huggins peaks. The estimated uncertainty in the 360–400 nm region is greater, 1.1 (1σ), primarily due to the spread in the available data sets.

Table 4A-2-2. Recommended Absorption Cross Sections of O₃ at 218 and 293–298 K

λ (nm)	$10^{20} \sigma$ (cm ² molecule ⁻¹)		λ (nm)	$10^{20} \sigma$ (cm ² molecule ⁻¹) 293–298 K
	218 K	293–298 K

Photolysis Quantum Yields and Product Studies. The recommendation for the O(¹D) quantum yield from ozone photolysis as a function of wavelength and temperature, based on the review of Matsumi et al.,⁴⁸ is given by the expression (Eqn 4-1)

$$\Phi(\lambda, T) = \left(\frac{q_1}{q_1 + q_2} \right) \times A_1 \times \exp \left\{ - \left(\frac{X_1 - \lambda}{\omega_1} \right)^4 \right\} + \left(\frac{q_2}{q_1 + q_2} \right) \times A_2 \times \left(\frac{T}{300} \right)^2 \times \exp \left\{ - \left(\frac{X_2 - \lambda}{\omega_2} \right)^2 \right\} \\ + A_3 \times \left(\frac{T}{300} \right)^{1.5} \times \exp \left\{ - \left(\frac{X_3 - \lambda}{\omega_3} \right)^2 \right\} + c \quad \text{Eqn 4-1}$$

where $q_i = \exp \left(- \frac{v_i}{RT} \right)$ and X_{1-3} , A_{1-3} , ω_{1-3} , v_{1-2} and c are best-fit parameters given in Table 4A-2-3, λ is in nm,

T is in K, and $R = 0.695 \text{ (cm}^{-1} \text{ K}^{-1})$. The parameter c is assumed to be temperature and wavelength independent. This expression is valid only for the wavelength range 306–328 nm and temperature range 200–320 K.

Table 4A-2-3. Parameters for the Calculation of O(¹D) Quantum Yields

Parameter	i = 1	i = 2	i = 3
X_i (nm)	304.225	314.957	310.737
ω_i (nm)	5.576	6.601	2.187
A_i	0.8036	8.9061	0.1192
v_i (cm ⁻¹)	0	825.518	–
c	0.0765	–	–

At room temperature (298 K) the uncertainties of the quantum yield values calculated with the above expression are estimated to be $\pm 10\%$ (1σ) for $\Phi(\lambda, 298 \text{ K}) \geq 0.4$, while the uncertainties are estimated to be ± 0.04 for $\Phi(\lambda, 298 \text{ K}) < 0.4$. At temperatures other than room temperature, the uncertainties are estimated to be $\pm 15\%$ for $\Phi(\lambda, T) \geq 0.4$ and ± 0.06 for $\Phi(\lambda, T) < 0.4$.

In the wavelength range 329–340 nm the recommended value of $\Phi(\text{O}^1\text{D}) = 0.08 \pm 0.04$, independent of temperature. For $\lambda > 340$ nm, the quantum yield may be non-zero but no recommendation is made. For the wavelength range 220–305 nm, the recommended O(¹D) quantum yield is 0.90, independent of temperature, based on the study by Takahashi et al.⁶⁹ and the review by Matsumi and Kawasaki.⁴⁹ The quantum yield for O(¹D) formation in the range 193–225 nm was measured by Nishida et al.⁵⁶ who found that the O(¹D) yield decreased from 0.90 ± 0.12 (225 nm) to 0.48 ± 0.03 (193 nm). A simple expression in the wavelength range 193–225 nm was derived

$$\Phi_{\text{O}^1\text{D}}(\lambda) = 1.37 \times 10^{-2} \lambda - 2.16$$

Matsumi et al.⁴⁸ derived the recommended values for the temperature and wavelength dependences of $\Phi(\text{O}^1\text{D})$ using the following procedure: the measured O(¹D) quantum yields at 298 K between 306 and 328 nm from eight studies (Talukdar et al.,⁷³ Takahashi et al.,⁷⁰ Ball et al.,¹⁰ Armerding et al.,⁶ Bauer et al.,¹⁴ which superseded the data of Silvente et al.⁶⁴ from the same group, Brock and Watson,²² Trolier and Wiesenfeld,⁷⁵ and Smith et al.⁶⁶ were normalized using $\Phi(\text{O}^1\text{D}) = 0.79$ at 308 nm. This value was derived from the studies listed in Table 1 of Matsumi et al.⁴⁸ The renormalized data were then averaged. The wavelength dependence quantum yield data at various temperatures reported by Talukdar et al.,^{72,73} Takahashi et al.,⁷⁰ Hancock and Hofzumahaus³⁸ (this includes all the data from the Oxford group), Bauer et al.,¹⁴ and Smith et al.⁶⁶ were normalized to the value at 308 nm given above. These normalized data were used to obtain the best fit parameters for Eqn. 4-1 for the wavelength range 306–328 nm and temperature range 200–320 K. Because of the large number of studies upon which the 298 K evaluation is based, the averaged 298 K data were given a larger weight in the fitting procedure than the data at other temperatures. The recommended O(¹D) quantum yields calculated from Eqn. 4-1 using the fitting parameters given in Table 4A-2-3 are shown in Figure 4-1 for 200, 253, and 298 K in the wavelength range 306–328 nm (solid lines).

Products and yields from O₃ photodissociation at 157.6 nm were measured by Taherian and Slinger.⁶⁸ The primary atomic oxygen yield was measured to be 1.90 ± 0.30 , of which 71% is O(³P) and 29% O(¹D). Turnipseed et al.⁷⁶ measured the quantum yield for O(³P) and O(¹D) formation from 193 nm photolysis to be 0.57 ± 0.14 and 0.46 ± 0.29 , respectively, and at 222 nm they observed a quantum yield of 0.13 ± 0.02 for O(³P) and 0.87 ± 0.04 for O(¹D).

Lee et al.⁴⁴ reported an upper limit of $< 0.1\%$ for the quantum yield for the formation of O(¹S) via channel (8) in the 170–240 nm range. Takahashi et al.⁷¹ measured the quantum yield of O(¹S) formation to be (2.5 ± 1.1)

$\times 10^{-3}$ in the 193 nm photolysis of O_3 , while Nakayama et al.⁵⁴ reported $(1.4 \pm 0.4) \times 10^{-4}$ and $(5 \pm 3) \times 10^{-5}$ for the $O(^1S)$ formation at 215 and 220 nm, respectively.

Figure 4A-1. Recommended $O(^1D)$ quantum yields calculated from Eqn. 4-1 using the fitting parameters given in Table 4A-2-3 for 200, 253 and 298 K in the wavelength range 306–328 nm (solid lines), based on Matsumi et al.⁴⁸ Contributions from different photolysis channels are indicated: region I corresponds to $O(^1D)$ formed via channel (5), $O(^1D) + O_2(a^1\Delta_g)$, region II (vertical hatching) represents the contribution of the hot-band excitation process via channel (5), while region III (diagonal hatching) corresponds to the contribution of $O(^1D)$ via the spin-forbidden channel (4), $O(^1D) + O_2(X^3\Sigma_g^-)$.

SECTION 4B. HO_x PHOTOCHEMISTRY

B1. HO₂ (hydroperoxyl radical)

[Back to Index](#)

(Recommendation: 06-2; Note: 10-6; Evaluated: 10-6)

Absorption Cross Sections: UV absorption cross sections of HO₂ in the wavelength range 190–260 nm have been measured at room temperature by Paukert and Johnston,¹² Hochanadel et al.,⁴ Cox and Burrows,¹ McAdam et al.,¹⁰ Kurylo et al.,⁵ Moortgat et al.,¹¹ Dagaut and Kurylo,³ Lightfoot and Jemi-Alade,⁸ who measured the cross sections at temperatures up to 777 K, Crowley et al.,² Maricq and Szente,⁹ Roehl et al.,¹³ and Sander et al.¹⁴ The HO₂ absorption cross section studies have been evaluated in reviews by Lightfoot et al.,⁷ Wallington et al.,¹⁶ and Tyndall et al.¹⁵ Discrepancies in the shape of the HO₂ spectrum and its absolute cross sections, particularly around 200 nm, exist among the available studies. Tyndall et al.¹⁵ recommend absolute HO₂ cross sections based on a comparison of absorption cross sections for HO₂, CH₃O₂ and C₂H₅O₂ at 240 nm obtained by Roehl et al., Lightfoot and Jemi-Alade, and Maricq and Szente combined with the measurements by Crowley et al.² at 240 nm. Tyndall et al.¹⁵ used the expression

$$\sigma = \left(\frac{\sigma_{med}}{1 - \frac{b}{\nu}} \right) \exp \left\{ -a \left[\ln \frac{(\nu - b)}{(\nu_{med} - b)} \right]^2 \right\}$$

where $\sigma_{med} = 1.64 \times 10^{-18}$ cm² molecule⁻¹, $a = 4.91$, $b = 30612$ cm⁻¹ and $\nu_{med} = 50260$ cm⁻¹ that reproduces the HO₂ spectrum over the wavelength range 190–250 nm. They recommend that the spectrum be treated as temperature independent over the range 200–300 K. The recommended HO₂ cross sections in Table 4B-1 are taken from the Tyndall et al.¹⁵ review.

Photolysis Quantum Yield and Product Studies: Lee⁶ detected O(¹D) as a primary photodissociation product of HO₂ at 193 and 248 nm with a quantum yield that is about 15 times larger at the longer wavelength. An absolute quantum yield for O(¹D) production has not been reported.

Table 4B-1. Recommended Absorption Cross Sections of HO₂ at 298 K

λ (nm)	$10^{20} \sigma$ (cm ² molecule ⁻¹)
190	368
195	402

→ O(³ P) + H + H	927 kJ mol ⁻¹	129 nm	(5)

(Recommendation: 10-6, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The VUV absorption spectrum of water vapor can be divided up into four main regions: (i) a broad continuum at wavelengths 145–190 nm with a maximum around 165 nm and the cross sections falling off rapidly toward longer wavelengths; (ii) a second continuum centered around 128 nm, which shows some diffuse vibrational structure; (iii) between 124–100 nm the absorption spectrum is dominated by progressions of sharp structured rovibronic peaks associated with Rydberg transitions; (iv) below 100 nm the spectrum is also a continuum consisting of two diffuse bands with maxima near 90 and 65 nm. In the atmosphere, water vapor is photodissociated mainly by the solar Lyman-α line (121.567 nm). The absorption cross sections and the photochemistry of water vapor were reviewed by Hudson,^{22,23} Hudson and Kiefer,²⁴ Calvert and Pitts,⁶ and Okabe.³⁸ Table 4B-2-1 summarizes the studies performed since 1950.

Table 4B-2-1. Summary of H₂O Vapor Absorption Cross Section Studies

Study	Year	Molecule	Wavelength (nm)	Resolution (nm)	Temperature (K)
Wilkinson and Johnston ⁵³	1950	H ₂ O	143–186	0.1	303

The cross sections in the VUV band in the range 6 to 110 nm measured by Katayama et al.,²⁶ Gürtler et al.,¹⁹ Phillips et al.,⁴⁰ Tan et al.,⁴⁴ Lee and Suto,³⁰ Chan et al.⁹ are in good agreement, whereas the data of Wainfan

et al.,⁵⁰ Metzger and Cook,³⁴ de Reilhac and Damany,¹⁵ Bennett et al.,³ and Branton and Brion⁴ show substantial deviations.

In the strong structured region between 100 and 125 nm, cross sections were measured at low resolution by Watanabe and Zelikoff,⁵² Watanabe and Jursa,⁵¹ Tan et al.,⁴⁴ Lee,²⁹ Lee and Suto,³⁰ Chan et al.,⁹ and at high resolution by Gürtler et al.,¹⁹ Lewis et al.,³¹ The Harvard-Smithsonian Center for Astrophysics,¹ Fillion et al.,¹⁸ and Mota et al.³⁶

Absorption cross sections were reported at the Lyman- α wavelength, 121.567 nm, in units 10^{-17} cm² molecule⁻¹, to be 1.44 ± 0.04 by Watanabe and Zelikoff,⁵² 1.4 ± 0.3 by Nicolet,³⁷ 1.5 ± 0.1 by Gürtler et al.,¹⁹ 1.55 ± 0.1 by Lewis et al.,³¹ 1.59 ± 0.1 by Kley,²⁷ 1.42 ± 0.1 by Lee,²⁹ 1.3 ± 0.05 by Chan et al.,⁹ 1.4 ± 0.03 by Yoshino et al.,⁵⁴ 1.6 ± 0.1 by Brownsword et al.,⁵ and 1.6 ± 0.1 by Vatsa and Volpp.⁴⁹ An average value $(1.48 \pm 0.10) \times 10^{-17}$ cm² molecule⁻¹ for the absorption cross section at the Lyman- α wavelength 121.567 nm is recommended.

In the weak structured region between 125 and 140 nm, measurements at low resolution were reported by Watanabe and Zelikoff,⁵² Laufer and McNesby,²⁸ Schürgers and Welge,⁴¹ Branton and Brion,⁴ Tan et al.,⁴⁴ Lee,²⁹ Lee and Suto,³⁰ Chan et al.,⁹ and at high resolution by Yoshino et al.,⁵⁴ Cheng et al.,¹⁰ and Mota et al.³⁶

In the broad continuum at long wavelengths 145–190 nm, measurements at low resolution were performed by Wilkinson and Johnston,⁵³ Watanabe and Zelikoff,⁵² Harrison et al.,²⁰ Thompson et al.,⁴⁷ Laufer and McNesby,²⁸ Schürgers and Welge,⁴¹ Branton and Brion,⁴ Tan et al.,⁴⁴ Lee and Suto,³⁰ Chan et al.,⁹ and at high resolution by Yoshino et al.,⁵⁴ Chung et al.,¹² and Mota et al.³⁶

In the tail of the absorption band in the wavelength range 185–200 nm, measurements were reported by Cantrell et al.,⁸ Creasey et al.,¹⁴ Chung et al.,¹² Parkinson and Yoshino,³⁹ and Mota et al.³⁶ At the 184.94 nm Hg line, absorption cross sections were measured, in units 10^{-20} cm² molecule⁻¹, to be 7.8 by DeMore,¹⁶ 7.14 ± 0.2 by Cantrell et al.,⁸ 7.22 ± 0.22 by Creasey et al.,¹⁴ 10.1 ± 0.1 by Yoshino et al.,⁵⁴ 7.0 by Hofzumahaus et al.,²¹ and 7.3 (a value measured by J. Crowley, cited by Hofzumahaus et al.²¹). Based on the latter studies, the recommended value for the absorption cross section at 184.94 nm is $(7.1 \pm 0.2) \times 10^{-20}$ cm² molecule⁻¹ at 298 K.

High resolution spectra of water vapor and complete sets of line parameters have been measured in the visible region by Camy-Peyret et al.⁷ (369–606 nm), Mandin et al.³² (606–758 nm), Fally et al.¹⁷ (385–769 nm), Coheur et al.¹³ (385–769 nm), and for H₂¹⁸O by Tanaka et al.⁴⁶ (584–689 nm), and Tanaka et al.⁴⁵ (606–689 nm); in the near infrared by Mérienne et al.³³ (769–1081 nm), Aldener et al.² (926–952 nm), and Kassl et al.²⁵ (747–752 nm).

The recommended absorption cross sections listed in Table 4B-2-2 are taken from Yoshino et al.⁵⁴ for the range 121–182 nm, from Cantrell et al.⁸ for the range 183–191 nm, and from the interpolated data of Parkinson and Yoshino³⁹ for the range 192–198 nm.

Photolysis Quantum Yield and Product Studies: Stief et al.⁴³ reported a relative quantum yield of process (2) $\Phi_2[\text{H} + \text{OH}(\text{X}^2\Pi)] = 0.89$ and process (3) $\Phi_3[\text{H}_2 + \text{O}(^1\text{D})] = 0.11$ for the wavelength interval 105–145 nm, and $\Phi_2[\text{H} + \text{OH}(\text{X}^2\Pi)] \geq 0.99$ and $\Phi_3[\text{H}_2 + \text{O}(^1\text{D})] \leq 0.01$ for the interval 145–185 nm. Lee²⁹ measured the quantum yield of the emission of $\text{OH}(\text{A}^2\Sigma^+) \rightarrow \text{OH}(\text{X}^2\Pi)$ produced in process (4), varying between 2 and 11% in the wavelength range 105–135 nm. The quantum yields show a maximum of 11% at 130 nm, decreasing slowly with decreasing wavelengths. Ung⁴⁸ measured the relative quantum yields $\Phi_2[\text{H} + \text{OH}(\text{X}^2\Pi)] = 0.92$ and $\Phi_3[\text{H}_2 + \text{O}(^1\text{D})] = 0.08$ for the photolysis at 147 nm. At the Lyman- α wavelength (121.567 nm) a quantum yield for H atoms, Φ_{H} , of 1.02 was determined by Slinger and Black.⁴² They also measured a quantum yield for processes (2) + (4), $\Phi_2[\text{H} + \text{OH}(\text{X}^2\Pi)] + \Phi_4[\text{OH}(\text{A}^2\Sigma^+) + \text{H}]$, of 0.78, for process (3), $\Phi_3[\text{O}(^1\text{D}) + \text{H}_2]$, of 0.10, and for process (5), $\Phi_5[\text{O}(^3\text{P}) + \text{H} + \text{H}]$, of 0.12. Chou et al.¹¹ photolyzed HTO at 174 nm and estimated $\Phi_1 \leq 0.003$ for the formation of $\text{HT} + \text{O}(^3\text{P})$ and $\Phi_2 \sim 1$ for the processes leading to $\text{H} + \text{OT}$ and $\text{T} + \text{OH}$. Mordant et al.³⁵ determined the absolute branching for the photodissociation channels at 121.567 nm as $\Phi_2[\text{H} + \text{OH}(\text{X}^2\Pi)] = 0.64$, $\Phi_3[\text{O}(^1\text{D}) + \text{H}_2] = 0.11$, $\Phi_4[\text{OH}(\text{A}^2\Sigma^+) + \text{H}] = 0.14$, and $\Phi_5[\text{O}(^3\text{P}) + \text{H} + \text{H}] = 0.11$.

B3. H₂O₂ (hydrogen peroxide)

[Back to Index](#)

H ₂ O ₂ + hν → OH + OH	215 kJ mol ⁻¹	557 nm	(1)
→ H ₂ O + O(¹ D)	333 kJ mol ⁻¹	359 nm	(2)
→ H + HO ₂	369 kJ mol ⁻¹	324 nm	(3)

(Recommendation: 90-1, Note: 15-10, Evaluated: 15-10)

Absorption Cross Sections: Absorption cross sections of hydrogen peroxide, H₂O₂, have been reported by a number of groups as summarized in Table 4B-3-1. The H₂O₂ spectrum is continuous and the absorption cross sections decrease monotonically from 180 nm toward longer wavelengths. The cross section data from the

studies performed after 1972 at wavelengths <350 nm are in reasonable agreement. Studies prior to 1977 are not considered for the recommendation. Nicovich and Wine¹¹ measured cross sections relative to the absolute values at 202.6 nm, $\sigma = 4.32 \times 10^{-19} \text{ cm}^2$, and 228.8 nm, $\sigma = 1.86 \times 10^{-19} \text{ cm}^2$, recommended in DeMore et al.¹ Knight et al.⁷ normalized their spectra to the spectra of Nicovich and Wine¹¹ between 250 nm and 280 nm. The spectra measured by Knight et al.⁷ at $\lambda > 290 \text{ nm}$ are in excellent agreement with those reported by Nicovich and Wine¹¹ at all the temperatures studied. Kahan et al.⁶ measured the absorption spectrum at 297 K between 353 and 410 nm, i.e., longer wavelengths than in previous studies, and quantified the spectrum using online absorption measurements at 213.9 nm (Zn line). Their absolute cross sections show a significant discontinuity with the recommended spectrum at shorter wavelengths. The Kahan et al. study demonstrates that H₂O₂ absorbs at the longer wavelengths and would contribute to the atmospheric photolysis loss of H₂O₂. However, due to the apparent disagreement with the previous absolute spectrum measurements at shorter wavelengths, a recommendation in this wavelength region is not given. The recommended 2 σ uncertainty factors are 1.1 for the wavelength range 190 to 300 nm and 1.25 for the wavelength range 300 to 350 nm.

Vatsa and Volpp²¹ measured the Lyman- α (121.567 nm) absorption cross section to be $9.8 \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1}$, which is recommended. Primarily because there is only a single study at Lyman- α rather large uncertainty factor of 1.4 is recommended.

Table 4B-3-1. Summary of H₂O₂ Absorption Cross Section Studies

Study	Year	Wavelength Range (nm)	Temperature (K)
Urey et al. ¹⁷	1929	215–275	298
Fergusson et al. ²	1936	220–290	298
Holt et al. ⁵	1948	155–220	298
Schumb et al. ¹⁴	1955	200–400	298
Schürgers and Welge ¹⁵	1968	125–200	298
Troe ¹⁶	1969	220–290	300
Hochenadel et al. ⁴	1972	185–260	298
Molina et al. ¹⁰	1977	210–350	296
Lin et al. ⁸	1978	195–350	296
Molina and Molina ⁹	1981	190–350	298
Nicovich and Wine ¹¹	1988	193–350	296, 285–381
Vaghjiani and Ravishankara ¹⁸	1989	210–345	297
Vatsa and Volpp ²¹	2001	121.567	300
Knight et al. ⁷	2002	250–350	273, 296, 343
Kahan et al. ⁶	2012	353–410	297

The recommended 298 K absorption cross section values for wavelengths <260 nm in Table 4B-5 are the mean of the data from Lin et al.,⁸ Molina and Molina,⁹ Nicovich and Wine,¹¹ and Vaghjiani and Ravishankara.¹⁸ Molina and Molina⁹ supersedes the results of Molina et al.¹⁰

The temperature dependence of the absorption spectrum has been measured by Nicovich and Wine¹¹ and Knight et al.⁷ The results of Nicovich and Wine and Knight et al. are in excellent agreement. Nicovich and Wine¹¹ parameterized the temperature dependence for wavelengths >260 nm as the sum of two temperature dependent components, σ_0 and σ_1 , using the expression given in Table 4B-3-2. In this parameterization, σ_0 represents absorption from the ground vibrational state and σ_1 represents absorption from the O-O stretch vibrational level. The expression given in Table 4B-3-2 is recommended and the 298 K cross section values obtained from this parameterization for wavelengths >260 nm are given in Table 4B-3-3.

Table 4B-3-2. Mathematical Expression for Absorption Cross Sections of H₂O₂ as a Function of Temperature

$$10^{21} \sigma(\lambda, T) = \chi \sum_{n=0}^7 A_n \lambda^n + (1 - \chi) \sum_{n=0}^4 B_n \lambda^n$$

where T: temperature K; λ : nm; $\chi = (1 + \exp(-1265/T))^{-1}$

$A_0 = 6.4761 \times 10^4$	$B_0 = 6.8123 \times 10^3$
$A_1 = -9.2170972 \times 10^2$	$B_1 = -5.1351 \times 10^1$
$A_2 = 4.535649$	$B_2 = 1.1522 \times 10^{-1}$
$A_3 = -4.4589016 \times 10^{-3}$	$B_3 = -3.0493 \times 10^{-5}$
$A_4 = -4.035101 \times 10^{-5}$	$B_4 = -1.0924 \times 10^{-7}$
$A_5 = 1.6878206 \times 10^{-7}$	
$A_6 = -2.652014 \times 10^{-10}$	
$A_7 = 1.5534675 \times 10^{-13}$	

Range 260–350 nm; 200–400 K

Table 4B-3-3. Recommended Absorption Cross Sections of H₂O₂ Vapor at 298 K

λ (nm)	$10^{20} \sigma$ (cm ² molecule ⁻¹)
190	67.2
195	56.4
200	47.5
205	40.8

260–350 nm: Nicovich and Wine,¹¹ parameterization

Photolysis Quantum Yields and Product Studies. The photodissociation quantum yield is thought to be unity. At and above 248 nm, the major photodissociation process is that leading to OH, i.e., the quantum yield for OH production is 2 (Vaghjiani and Ravishankara,¹⁹ Vaghjiani et al.,²⁰ Riffault et al.¹²). At 248 nm Vaghjiani and Ravishankara¹⁹ reported $\Phi(\text{OH}) = 2.09 \pm 0.36$, $\Phi(\text{O}) < 0.002$, and $\Phi(\text{H}) < 0.0002$. Schiffman et al.¹³ reported a slightly lower value for $\Phi(\text{OH})$ at 248 nm of 1.58 ± 0.23 ; at 193 nm they obtained $\Phi(\text{OH}) = 1.22 \pm 0.13$. At 222 nm Vaghjiani et al.²⁰ measured $\Phi(\text{OH}) = 2.02 \pm 0.35$, $\Phi(\text{O}) < 0.002$, and $\Phi(\text{H}) = 0.024 \pm 0.012$. At 193 nm they obtained $\Phi(\text{OH}) = 1.51 \pm 0.18$, $\Phi(\text{O}) < 0.02$, and $\Phi(\text{H}) = 0.16 \pm 0.04$. Riffault et al.¹² reported $\Phi(\text{OH})$ values of 1.93 ± 0.39 at 308 nm and 1.96 ± 0.50 at 320 nm. In addition, Gerlach-Meyer et al.³ reported $\Phi(\text{H}) = 0.12 \pm 0.01$ and Schiffman et al.¹³ reported $\Phi(\text{OH}) = 1.22 \pm 0.13$ for 193 nm photolysis in reasonable agreement with Vaghjiani et al.²⁰ An OH quantum yield of 2 for $\lambda > 230$ nm is recommended. For 193 nm $\Phi(\text{OH}) = 1.7$ and $\Phi(\text{H}) = 0.15$ are recommended.

SECTION 4C. NO_x PHOTOCHEMISTRY

C1. NO (nitric oxide)

[Back to Index](#)

NO + hν → Products

(New)

Absorption Cross Sections: VUV/UV absorption cross sections of NO (nitric oxide) have been measured at room temperature by Bertrand et al.¹ (123.6 nm), Chan et al.² (41.32–228.55 nm, graphical data), Chung et al.³ (90–134 nm, graphical data), Guest and Lee⁴ (106.4–196.3 nm, graphical data), Iida et al.⁵ (6.5–207 nm), Sun and Weissler⁶ (37–131 nm), Thompson et al.⁷ (186–227 nm, graphical data), Wang et al.⁸ (197–235 nm), and Watanabe et al.⁹ (58–135 nm). At wavelengths >150 nm, there are large discrepancies in the magnitude of the reported cross sections of Chan et al., Guest and Lee, Iida et al., Thompson et al., and Wang et al., which are due primarily to differences in the spectral resolution and pressure at which the spectra were obtained. No recommendation is given for this wavelength region.

For VUV wavelengths ≤135 nm, the available studies typically agree to within 50%. At the Lyman-α wavelength (121.567 nm), the cross section of Chung et al. is high relative to the other available studies, which all agree to within 25%. The recommended Lyman-α (121.567 nm) cross section given in Table 4C-1 is an average of the data of Chan et al., Guest and Lee, Iida et al., Sun and Weissler, and Watanabe et al. and has an estimated uncertainty factor (2σ) of 1.25.

Photolysis Quantum Yield and Product Studies: No recommendation.

C2. NO₂ (nitrogen dioxide)

[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV/vis absorption spectrum of nitrogen dioxide, NO₂, in the 200–800 nm region can be separated into two principal systems: the D-X band below 250 nm and the broad B-X and A-X bands between 300 and 800 nm with a maximum around 400 nm. The forbidden C-X transition also contributes to the visible spectrum. There is enormous spectral fine structure superimposed on the broad visible system. Due to the complexity of the electronic states of NO₂, it is not presently possible to predict its spectrum from molecular quantum theory within the accuracy of the experimental measurements. The absorption spectrum and cross sections of NO₂ have been extensively studied during the last century as summarized in Table 4C-2-1.

Table 4C-2-1. Summary of NO₂ Absorption Cross Section Studies

Study	Year	λ Range (nm)	Type*	Resolution (nm)	Temperature (K)

* The studies summarized in Table 4C-2-1 are organized into three measurement categories: *Type A*, absolute cross section measurements over a broad spectral region (typically covering a few hundred nm); *Type B*, absolute cross section measurements at specific wavelengths or over narrow spectral ranges; and *Type C*, relative NO₂ absorption spectrum measurements over broad spectral region (typically a few hundred nm) that have been scaled to absolute cross section values using results from other studies.

In the earlier studies, the NO₂ ultraviolet-visible absorption cross section measurements were limited to lower spectral resolution. Since 1992, however, several sets of high resolution measurements, including temperature and pressure dependence studies, have been reported by several groups, which mainly aimed at improving the accuracy of atmospheric measurements, in particular, for the atmospheric remote sensing of NO₂. However, a number of laboratory measurements were also obtained at spectral resolutions that are limited by instrumental techniques.

The NASA/JPL 97-04¹⁰ recommendation for the absorption cross sections of NO₂ was based on the work of Bass et al.,² Schneider et al.,³⁹ and Davidson et al.⁹ Although at room temperature the agreement between these three sets of measurements is good (within 5% between 305 and 345 nm and within 10% at the longer wavelengths), serious non-uniform wavelength calibration errors are apparent in the wavelength range 400–500 nm as described by Schneider et al.³⁹ At shorter wavelengths and for temperatures below 298 K the agreement among these three sets of data is poor. A possible cause for the discrepancies is the presence of N₂O₄, which is the weakly bound NO₂ dimer present in equilibrium with the monomer. The ratio of the abundance of the two species is concentration and temperature dependent. Corrections were needed to account for the presence of N₂O₄ at wavelengths below 400 nm and especially near 200 nm where N₂O₄ absorbs strongly.

Kirmse et al.²⁶ analyzed the spectra reported between 1976 and 1995 and concatenated selected (and corrected) cross sections to create a “new standard” spectrum in the range 300–708 nm at a resolution of 0.05 nm, and another spectrum extending to 908 nm at a lower resolution of 1 nm. This high resolution “new standard” spectrum consisted of the Mérienne et al.³⁰ cross sections from 300 to 500 nm, the Corcoran et al.⁷ cross sections from 500 to 600 nm, and the Schneider et al.³⁹ cross sections from 600 to 710 nm. A critical review and evaluation of the cross section studies was performed by Orphal³⁴ and Orphal,³⁷ covering most studies published since 1995. In his evaluations Orphal^{34,37} considered baseline problems, wavelength calibration and integrated cross sections (after convolution of high resolution cross sections of 0.1 nm or better). In addition, Vandaele et al.⁴² derived temperature and pressure dependent parameters from high resolution spectral data obtained since 1995.

At room temperature (295 ± 3 K) there is agreement to better than 2–3% among the absolute cross sections over the wavelength range covered by the measurements of Mérienne et al.,³⁰ Coquart et al.,⁶ Vandaele et al.,⁴³ Jenouvrier et al.,²² Yoshino et al.,⁴⁷ Mérienne et al.,²⁹ Vandaele et al.,⁴⁴ Bogumil et al.,³ and Nizkorodov et al.³³ Many of these studies differ in spectral resolution, an issue relevant to atmospheric remote sensing applications. The cross sections of Harwood and Jones¹⁹ are 6–8% below most of the other studies, while the data of Harder et al.¹⁷ are systematically 2–5% higher than the data of Vandaele et al.⁴⁴ (1998) and show a systematic baseline drift of up to 10% at the lowest temperature.

The high pressure cross section data of Vandaele et al.⁴¹ (2002) and Vandaele et al.⁴² (2003) are nearly 4% smaller than the Vandaele et al.⁴³ (1996) and Vandaele et al.⁴⁴ (1998) data. The cross sections of Burrows et al.⁴ are about 6–8% lower than most recent high resolution studies (Mérienne-95, Mérienne-97, Harder, Vandaele-96, Vandaele-98). The data of Voigt et al.⁴⁵ show several artificial peaks (probably Xenon lamp stray light) of a few percent and baseline shifts up to 10% (partly due to residual N₂O₄ absorption) at lower

temperatures. The spectra of Bogumil et al.³ were scaled to absolute values using the integrated cross section of Vandaele et al.⁴⁴ (1998).

The temperature effect on the NO₂ absorption cross sections has been studied by only a few research teams, as given in Table 4C-2-1. The variation of the absorption consists mainly in an increase of the differential absorption cross sections with decreasing temperature. In his analysis of the temperature dependence of the cross sections in the 300–700 nm region, Orphal³⁵ (2003) observed a tilt in the baseline with decreasing temperature in the data of Davidson et al.,⁹ Burrows et al.,⁴ and Bogumil et al.³ but less pronounced in the data of Harwood and Jones,¹⁹ Harder et al.,¹⁷ and Vandaele et al.⁴¹ (2002). This is due to a change in the thermal population of the lower vibrational and rotational states causing large discrepancies in the relative change and the absolute magnitude of the absorption cross sections. The comparison of the high resolution absolute cross sections at temperatures below ambient reveals significant discrepancies in absolute magnitude of cross sections due to spectral resolution, baseline differences and possible wavelength calibration. For the temperatures 242 ± 2 and 220 ± 3 K, the overall agreement is within 15% in the region 350–500 nm, however outside this range the discrepancies are much larger. The integrated cross sections for the range 400–500 nm were calculated by Orphal³⁵ (2003) to be $(4.50 \pm 0.10) \times 10^{-17}$ cm² molecule⁻¹ nm and are independent of temperature, as recently shown by Nizkorodov et al.³³ for the temperature range 215–298 K.

Orphal³⁵ (2003) and Vandaele et al.⁴² (2003) compared the spectra after degrading the high resolution spectra to a lower resolution. At 220 K the best agreement (within 1.6%) is obtained between the data of Coquart et al.,⁶ Mérienne et al.²⁹ (1997), and Vandaele et al.⁴⁴ (1998). The data of Harder et al.¹⁷ differ by 3.7% from the Vandaele et al.⁴⁴ (1998) data below 500 nm but seem to contain more noise at longer wavelengths. The data of Voigt et al.⁴⁵ show larger disagreement, which is different in every temperature data set. At 223 K their data are 22% lower than the Vandaele et al.⁴⁴ (1998) values.

The temperature dependence of the NO₂ cross sections in the entire ultraviolet and visible regions can be reproduced within the experimental uncertainties using analytical expressions, at least at low and moderate spectral resolutions (i.e., 0.05 nm and less). Linear functions were proposed by Davidson et al.,⁹ Kirmse et al.,²⁶ and Vandaele et al.⁴¹ (2002), a quadratic polynomial by Burrows et al.,⁴ and a double exponential function by Voigt et al.⁴⁵ For the high resolution spectra Nizkorodov et al.³³ concluded that a linear temperature dependence is not valid and a successful parameterization requires further work.

The NO₂ cross sections vary as a function of total pressure but these effects are only observed at high spectral resolution, i.e., better than 0.01 nm, as investigated by Harder et al.,¹⁷ Wennberg et al.,⁴⁶ Vandaele et al.⁴⁴ (1998), Voigt et al.,⁴⁵ Vandaele et al.⁴¹ (2002), and Nizkorodov et al.,³³ using NO₂/N₂ (or air) mixtures at total pressures up to 1 atm. Nizkorodov et al.³³ showed that a simple Lorentzian broadening model with linear dependence of the Lorentz width on pressure provides an adequate description of the pressure broadening effects in NO₂.

The current recommendation is based on the data of Vandaele et al.⁴⁴ (1998). Table 4C-2-2 lists recommended cross sections for 294 and 220 K averaged over atmospherically relevant intervals.

Photolysis Quantum Yield and Product Studies: A number of NO₂ photolysis quantum yield studies in the atmospherically important 300–470 nm region have been reported: Jones and Bayes²⁴ for the wavelength range 295–445 nm and at 492 nm, 546 nm and 579 nm; Gaedtke and Troe¹³ in the range 313–416 nm; Harker et al.¹⁸ for the range 375–420 nm at 1 nm intervals; Davenport⁸ for the range 390–420 nm at 223 and 300 K; Gardner et al.¹⁴ for the range 334–404 nm at 298 K, and at 404 nm at 273 and 370 K; and Roehl et al.³⁸ in the range 388–411 nm at 248 and 298 K. In the range 360–398 nm the Φ_1 values show a wide scatter, with differences of as much as 60%, especially for the data of Harker et al.¹⁸ Although Gardner et al.¹⁴ obtained values of Φ_1 between 0.89 ± 0.05 and 0.97 ± 0.06 in the range 379–397 nm, they made a critical assessment of the quantum yield data and recommended that Φ_1 is near unity at wavelengths up to and slightly beyond the dissociation limit of $\lambda_0 = 397.95$ nm (Jost et al.²⁵) and then rapidly decreases to near zero at 424 nm. However, Roehl et al.³⁸ determined $\Phi_1 = (0.93 \pm 0.10)$ in the range 388–398 nm at 298 K, and $\Phi_1 = (0.90 \pm 0.10)$ at 248 K. Troe⁴⁰ conducted a critical reanalysis of the quantum yield data of Gardner et al.¹⁴ and Roehl et al.³⁸ below λ_0 and concluded that certain secondary reactions were not correctly accounted for, and recommended corrections for both data sets. The recommended quantum yield values in Table 4C-2-3 are based on the data of Roehl et al.³⁸ as corrected by Troe.⁴⁰

Table 4C-2-2. Recommended Absorption Cross Sections of NO₂ at 220 and 294 K

(Recommendation: 06-2; Note: 10-6; Evaluated: 10-6)

Absorption Cross Sections: The visible absorption spectrum of the NO₃ radical contains ~20 diffuse bands between 400 and 700 nm, Figure 4C-3-1. The most intense features are the bands for the 0-0 and 1-0 transitions in the symmetric N-O stretching vibration in the excited state that are centered at 662 and 623 nm, respectively. The absorption cross section of the 0-0 band at 662 nm is of special interest, since it is commonly used to monitor NO₃ both in the laboratory and in the atmosphere.

The absorption cross sections of NO₃ have been the subject of many laboratory studies. The spectroscopy of NO₃ has been reviewed by Wayne et al.²¹ Although there is good agreement for the positions of the absorption features, the range in reported absolute cross sections is nearly a factor of two. The studies and reported cross sections values at the 662 nm peak are summarized in Table 4C-3-1.

Table 4C-3-1. Summary of NO₃ Absorption Cross Section Studies

	Study	Year	NO ₃ source Technique	T (K)	λ (nm)	Resolution (nm)	$\sigma(662 \text{ nm})$ (10 ⁻¹⁷ cm ²)

^a Estimate for 300 K by Wayne et al.²¹ from the data of Schott and Davidson.¹⁹

^b Improvement by Graham and Johnston⁶ using their more actual kinetic data.

^c The overall uncertainty (± 15%) includes the uncertainty of the absorbance measurement (± 5%) and the uncertainty of σ(ClONO₂) (± 10%). The value for σ(662 nm) obtained by the flash photolysis method is preferred by Sander¹⁷ over that obtained by the discharge flow method.

^d Recommendation by Wayne et al.²¹

The NASA/JPL 02-25¹⁸ evaluation recommended a cross section value of $(2.00 \pm 0.25) \times 10^{-17}$ cm² molecule⁻¹ at 662 nm derived from an average of the results from studies 5, 6, and 8-12 given in Table 4C-3-1. The recommendation by Wayne et al.²¹ averaged the data of the more recent studies, studies 9-12, and resulted in a slightly higher value of $(2.10 \pm 0.20) \times 10^{-17}$ cm² molecule⁻¹. Higher values for the absorption cross section at 662 nm were obtained in the more recent studies by Yokelson et al.²² and Orphal et al.¹³ Here, the results from Sander¹⁷ and Yokelson et al.²² are averaged to derive a recommended cross section of $(2.25 \pm 0.15) \times 10^{-17}$ cm² molecule⁻¹ at 662 nm. The recommended absorption cross sections at other wavelengths in Table 4C-3-2 are taken from Sander¹⁷ after normalization to this value, which is actually only a reduction of 1.3% from the originally reported data.

The studies of the absorption spectrum temperature dependence indicate an increase of the 662 nm peak absorption cross section with decreasing temperature. Ravishankara and Mauldin¹⁵ reported an increase of 42% between 298 and 220 K. Sander¹⁷ reported an increase of 17% between 298 and 230 K. Yokelson et al.²² reported increases of 34% between 298 and 200 K and 24% between 298 and 230 K. Osthoff et al.¹⁴ reported a decrease of 48% between 298 and 388 K. Cantrell et al.³ reported a temperature independent cross section over the temperature range 210–348 K of 2.06×10^{-17} cm² molecule⁻¹ that is in disagreement with the findings from the other studies. Osthoff et al.¹⁴ combined their data with the data from Yokelson et al.²² and modified the parameterization given by Yokelson et al.²² for the peak cross section temperature dependence slightly as:

$$\sigma(662 \text{ nm}, T) = (4.582 \pm 0.096) - [(0.00796 \pm 0.0031) \times T] \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$$

for the range 220–388 K. Orphal et al.¹³ interpreted the temperature dependence as resulting from changes in the ground vibrational state population of NO₃ (D_{3h} symmetry) and derived a formula for the cross section ratio as function of temperature:

$$\sigma(T)/\sigma(298 \text{ K}) = [1 - \exp(-1096.4/T) - 2 \exp(-529.5/T)] / [1 - \exp(-1096.4/298.0) - 2 \exp(-529.5/298.0)]$$

where the values of 1096.4 K and 529.5 K are the vibrational energies of 762 cm⁻¹ and 368 cm⁻¹ divided by the Boltzmann constant. There is excellent agreement between the calculated temperature dependence using the Orphal model and the empirical relationships from Yokelson et al.²² and Osthoff et al.¹⁴

Photolysis Quantum Yield and Product Studies: The quantum yields Φ₁ and Φ₂ have been measured by Graham and Johnston,⁶ and at higher spectral resolution by Magnotta and Johnston,⁹ who report the product of the cross section times the quantum yield in the 400 to 630 nm range. The total quantum yield value, Φ₁ + Φ₂, computed from the results of Magnotta and Johnston⁹ and the cross sections of Graham and Johnston,⁶ is about 1.5 for λ < 585 nm, based on the nearly constant yield of the major product O(³P), and a quantum yield for the NO production Φ₁ near zero. Because systematic errors seem to exist in these data, in their review Wayne et al.²¹ normalized Φ₂ quantum yields to unity at λ < 585 nm. The quantum yield for the NO production, Φ₁, increases from zero at 585 nm to a maximum of Φ₁ = 0.35 at 595 nm, where Φ₂ = 0.65. At longer wavelengths both Φ₁ and Φ₂ decrease to a value of zero at λ = 640 nm. Orlando et al.¹² measured the O(³P) and NO quantum yields in the photolysis of NO₃ between 570 and 635 nm. They qualitatively confirm the earlier measurements by Johnston and coworkers but provide more accurate data for both channels. The O(³P) quantum yield was found to be unity in the wavelength range 570–585 and to decrease to 0.1 at 635 nm. They observed anomalously low O(³P) yields in the region of the strong absorption band near 623 nm. The quantum yields for NO formation were < 0.10 at 580 nm and 0.20 ± 0.10 near 590 nm. The wavelength dependence of Φ₁ and Φ₂ are similar to those recommended in the review of Wayne et al.²¹

In a molecular beam study, Davis et al.⁵ investigated the photodissociation processes of NO₃ over the wavelength range 532–662 nm and determined a sharp threshold for the dissociation of internally cold NO₃ into NO₂ and O(³P) at 587 nm. At shorter wavelengths, e.g. 585 nm, the NO + O₂ yield dropped to <0.05. At excitation energies just below this threshold, i.e., $\lambda = 588$ nm, a large quantum yield (0.70 ± 0.10) for a concerted three-center rearrangement was observed, resulting in NO + O₂(³ Σ_g^- , ¹ Δ). The yield of this NO + O₂ process decreases at longer wavelengths to zero at 613 nm. At $\lambda > 588$ nm the O + NO₂ channel yield arises from vibrational excitation of the ground electronic state of NO₃. These results imply that for thermally equilibrated NO₃ the branching ratios for dissociation of both channels (1) and (2) will strongly depend on temperature, especially near the threshold wavelength.

Johnston et al.⁷ re-analyzed the available laboratory data relevant to NO₃ photolysis, including quantum yield data for NO and NO₂ formation, fluorescence, and threshold energies reported in the molecular beam study. Their model reproduces the wavelength dependent quantum yield values for $\Phi(\text{O} + \text{NO}_2)$, $\Phi(\text{NO} + \text{O}_2)$ and $\Phi(\text{fluorescence})$ at 190, 230, and 298 K. At 298 K the calculated $\Phi(\text{O} + \text{NO}_2)$ quantum yields agree reasonably well with those obtained by Orlando et al.,¹² but shows a systematic offset in the wavelength range 605–620 nm. The calculated $\Phi(\text{NO} + \text{O}_2)$ product yield agrees with those reported by Magnotta and Johnston⁹ within the scatter of the experimental data.

The recommended quantum yields in Table 4C-3-3 over the wavelength range 685–640 nm at 190, 230, and 298 K are taken from Johnston et al.⁷ For $\lambda < 585$ nm, $\Phi(\text{O} + \text{NO}_2) = 1$, and $\Phi(\text{NO} + \text{O}_2) = 0$ and for $\lambda > 640$ nm $\Phi(\text{O} + \text{NO}_2)$ and $\Phi(\text{NO} + \text{O}_2)$ are zero. Photodissociation rates have been calculated by Johnston et al.⁷ for overhead sun in the stratosphere to be

$$J(\text{NO} + \text{O}_2) = 0.0201 \text{ s}^{-1}$$

$$J(\text{NO}_2 + \text{O}) = 0.156 \text{ s}^{-1}$$

→ N(⁴ S) + NO(² Π)	482 kJ mol ⁻¹	248 nm	(3)
→ N ₂ + O(¹ S)	571 kJ mol ⁻¹	210 nm	(4)

(Recommendation: 06-2; Note: 15-10; Evaluated: 15-10)

Absorption Cross Sections: The VUV/UV absorption spectrum of nitrous oxide, N₂O, has been measured in numerous studies covering the wavelength range 108–315 nm at temperatures between 194 and 302 K. A summary of the available spectroscopic studies is given in Table 4C-4-1.

Table 4C-4-1. Summary of N₂O Cross Section Studies

Study	Year	Temperature (K)	Wavelength range (nm)	Resolution (nm)

Rontu Carlon et al. ²²	2010	210–350	184.95, 202.206, 206.200, 213.857, 228.8	atomic lines
SPARC Evaluation ¹³	2013	–	–	–

The N₂O spectrum has a broad absorption band between 160 and 260 nm with the peak near 182 nm ($\sigma_{\text{max}} = (1.24\text{--}1.47) \times 10^{-19} \text{ cm}^2 \text{ molecule}^{-1}$) and a stronger but weaker band between 137 and 160 nm with the maximum near 145 nm ($\sigma_{\text{max}} = (5\text{--}6) \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1}$). There is good agreement between the results from Selwyn et al.²³ and Hubrich and Stuhl.¹⁰ The agreement over the entire 160–260 nm band is better than 15% and the difference at 182 nm is 5% with the data of Selwyn et al.²³ being greater. The results of Mérienne et al.¹⁴ and Rontu Carlon et al.²² are in excellent agreement, better than 5% and 3%, respectively, with those of Selwyn et al.²³ The results of Cantrell et al.³ and Creasey et al.⁵ at 184.9 nm are also in good agreement with the results of Selwyn et al.²³ The high resolution absorption spectrum reported by Yoshino et al.²⁹ shows the diffuse vibrational structure around the maximum and their absolute cross sections are close to those reported by Hubrich and Stuhl.¹⁰ At wavelengths >250 nm, there are large discrepancies between the results from Bates and Hayes¹ and Johnston and Selwyn.¹² The recommended cross sections listed in Table 4C-4-2 are based on the room temperature results at 160, 165, and 170 nm of Hubrich and Stuhl¹⁰ and the room temperature data between 173–240 nm from Selwyn et al.²³

The VUV absorption spectrum of N₂O has been measured by Hitchcock et al.⁹ (16.8–155 nm) and Chan et al.⁴ (6.1–168 nm). The absorption cross section at 123.6 nm was measured by Bertrand et al.² The cross section results from Chan et al. and Hitchcock et al. agree to within 6% at 124 nm, while the value reported by Bertrand et al. is less by nearly a factor of 3. The reason for the difference is unknown. The recommended Lyman- α cross section is adopted from SPARC,¹³ which used a linear interpolation of the Chan et al. cross section data at 118 and 124 nm to obtain a Lyman- α cross section of $2.4 \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$ with an uncertainty factor of 1.5 (2 σ).

The temperature dependence of the N₂O absorption cross section in the atmospherically relevant wavelength region has been measured by Selwyn et al.,²³ Hubrich and Stuhl,¹⁰ Mérienne et al.,¹⁴ and Rontu Carlon et al.²² These studies report a decrease in absorption cross section with decreasing temperature. The Hubrich and Stuhl data has considerable scatter in the spectrum wavelength dependence and is not considered in the recommendation. The Rontu Carlon et al. study is in excellent agreement, to within 3%, with the NASA/JPL 10-6 recommendation at 202.206, 206.200, and 213.857 nm. There is a systematic difference in the cross section temperature dependence at 228.8 nm between the Mérienne et al. and Rontu Carlon et al. data and that of NASA/JPL 10-6, where the difference is ~18% at 210 K. The empirical cross section parameterization given by Selwyn et al.²³ given in Table 4C-4-3 is recommended.

On the basis of the Selwyn et al., Mérienne et al., and Rontu Carlon et al. studies, an uncertainty factor of 1.08 (2σ) is recommended for the 298 K absorption cross sections over the wavelength range 185–220 nm. The uncertainty factor at lower temperatures is estimated to be slightly greater with a value of 1.12 (2σ) at 200 K.

Isotopomer specific cross sections for ¹⁴N¹⁴NO, ¹⁵N¹⁴NO, ¹⁴N¹⁵NO, ¹⁵N¹⁵NO over the wavelength range 181–218 nm have been reported by von Hessberg et al.²⁸ at 233 and 283 K. They observed a slight decrease in the absorption cross sections of ¹⁴N¹⁵NO and ¹⁵N⁵NO compared to those of ¹⁴N¹⁴NO and ¹⁵N¹⁴NO. They also observed a systematic decrease in absorption cross section with decreasing temperature.

Photolysis Quantum Yield and Product Studies: The quantum yield for photodissociation is unity in the range 140–230 nm and the photoproducts are almost exclusively N₂ and O(¹D) (Zelikoff and Aschenbrand,³¹ Greiner,⁷ Paraskevopoulos and Cvetanovic,¹⁶ Preston and Barr,¹⁷ and Simonaitis et al.²⁵). The yield of N(⁴S) and NO(²II) is less than 1% (Greenblatt and Ravishankara⁶). Nishida et al.¹⁵ reported the yield of O(³P) at 193 nm to be 0.005 ± 0.002.

Several groups have investigated the isotopic fractionation of N₂O resulting from photolysis in the UV. Fractionation factors have been measured following photolysis at select wavelengths in the 193–213 nm range by Turatti et al.²⁷ (using high resolution FTIR spectroscopy), Röckmann et al.¹⁹ (using a modified isotope ratio mass spectrometric technique), Rahn et al.¹⁸ (utilizing isotope ratio mass spectrometry), and Zhang et al.³³ (using low resolution FTIR spectroscopy). Röckmann et al.²⁰ utilized a broadband photolysis source centered around 200 nm that simulated stratospheric actinic fluxes. The results are in reasonably good agreement and indicate that the fractionation factors increase with increasing wavelength between 193 and 213 nm. Furthermore, the fractionation factors show a clear dependence on the position of the ¹⁵N atom, in agreement with the theoretical zero point energy model of Yung and Miller.³⁰ However, the Yung and Miller calculations underestimate the laboratory results by about a factor of two. A more detailed Hermite propagation model used by Johnson et al.¹¹ achieved better agreement with experimental enrichment factors. Analysis of the isotopic composition of stratospheric air samples yields results that are in qualitative agreement with the laboratory results, confirming that photolysis is the predominant sink for N₂O.^{8,20} On the other hand, the fractionation factors measured in the atmospheric samples are smaller than those reported from the laboratory studies, indicating the influence of atmospheric diffusion and mixing (Röckmann et al.²⁰).

C5. N_2O_3 (dinitrogen trioxide)

[Back to Index](#)

(1)

(Recommendation: 19-5; Note: 19-5; Evaluated: 19-5)

Absorption Cross Sections: UV absorption cross sections of N_2O_3 (dinitrogen trioxide) have been reported at 298 K by Stockwell et al.² (300–400 nm). The Stockwell et al. measurements are the only UV absorption data currently available for this molecule; however, the identification of the measured spectrum as $\text{N}_2\text{O}_3(\text{g})$ was considered tentative in the original paper and has not been confirmed. The reader is referred to the Stockwell et al. paper for further information and the Mainz spectral atlas¹ for the digitized cross section data. No recommendation for the absorption cross sections of N_2O_3 is made.

Photolysis Quantum Yield and Product Studies: No recommendation.

C6. N_2O_4 (dinitrogen tetroxide)

[Back to Index](#)

57 kJ mol⁻¹

2090 nm

(1)

(Recommendation: 06-2; Note: 10-6; Evaluated: 10-6)

Absorption Cross Sections: The UV/vis absorption spectrum of dinitrogen tetroxide, N_2O_4 , has been derived from absorption measurements of NO_2 - N_2O_4 mixtures. The available studies are summarized in Table 4C-6-1. The N_2O_4 absorption spectrum consists of a band between 300 and 400 nm with a maximum at ~340 nm, a second less pronounced maximum near ~265 nm, and a strong absorption at shorter wavelengths with a maximum near 190 nm. For the wavelength region 185–360 nm, there is good agreement for the shape of the absorption spectrum but there are discrepancies in the absolute absorption cross sections. In the region below 240 nm, there is good agreement between the absorption cross sections of Bass et al.¹ and Schneider et al.⁸ whereas the values reported by Mérienne et al.⁶ are lower by ~30%. In the region between 250 and 300 nm, the results of Vandaele et al.⁹ are systematically lower than the results of Mérienne et al.⁶ by ~15% whereas the results of Bass et al.¹ are higher by ~30%. In the region 300–380 nm, Harwood and Jones³ reported a systematic study of the temperature dependence of the N_2O_4 absorption spectrum. The absorption cross sections near the peak at 340 nm show a weak dependence on temperature over the range 213–253 K. There is good agreement between the results of Hall and Blacet,² the low-temperature data of Harwood and Jones,³ and the results of Vandaele et al.⁹ with the absorption cross sections at 340 nm agreeing to within 5%. Bass et al.¹ and Mérienne et al.⁶ report cross section values at 340 nm that are 25% and 15% higher, respectively. The recommended cross section values in Table 4C-6-2 are averages over 2 nm intervals of the high resolution (0.01–0.03 nm) spectrum reported by Vandaele et al.⁹ between 252 and 390 nm at 220 K.

Photolysis Quantum Yield and Product Studies: No recommendation.

Table 4C-6-1. Summary of N₂O₄ Absorption Cross Section Studies

C7. N₂O₅ (dinitrogen pentoxide)

[Back to Index](#)

(Recommendation: 06-2; Note: 15-10; Evaluated: 15-10)

Absorption Cross Sections: The UV/vis absorption spectrum of dinitrogen pentoxide, N₂O₅, exhibits an absorption maximum at 160 nm with continuously decreasing absorption cross sections toward longer wavelengths. The absorption cross sections of N₂O₅ have been measured in a number of studies that are summarized in Table 4C-7-1. The room temperature values from Yao et al.¹⁴ and Harwood et al.³⁻⁵ agree to within 10-20% at wavelengths above 250 nm. Below 250 nm, the cross sections reported by Yao et al.¹⁴ that were recommended in the NASA/JPL 1997 evaluation are systematically higher than those reported by Harwood et al.³ by up to a factor of ~2 at 208 nm. A possible explanation for this discrepancy was proposed by Harwood et al.³ as due to contributions to the measured absorption by HNO₃ impurities. Harwood et al.³ used N₂O₅ samples containing less than a 1% HNO₃ impurity. This explanation was later confirmed by the measurements of Osborne et al.¹¹ who also used thoroughly purified N₂O₅ samples and reported absorption cross sections in agreement with those of Harwood et al.³ at 210–240 nm, but at a lower temperature.

The recommended absorption cross sections listed in Table 4C-7-2 are the mean of the data from Yao et al.¹⁴ and Osborne¹¹ for 200–208 nm, the mean of the data from Yao et al.,¹⁴ Osborne et al.,¹¹ and Harwood et al.³ for 210–240 nm, the data of Harwood et al.³ for 242–398 nm, and the data of Harwood et al.⁴ for 400–420 nm.

The temperature dependence of the absorption spectrum was measured by Harwood et al.³ and Yao et al.¹⁴ and found to be significant for wavelengths >280 nm. The absorption cross sections decrease with decreasing temperature and the magnitude of the effect increases with increasing wavelength. Harwood et al.⁴ parameterized the temperature dependence using the relationship

$$\log_{10}(\sigma) = A(\lambda) + 1000 \times B(\lambda)/T$$

which is valid over the temperature range 233–295 K. The A and B coefficients are given in Table 4C-7-2.

Table 4C-7-1. Summary of N₂O₅ Absorption Cross Section Studies

Study	Year	Temperature (K)	Wavelength (nm)
Holmes and Daniels ⁶	1934	273	265, 280
Jones and Wulf ⁹	1937	273	285–380
Johnston and Graham ⁸	1974	298	210–290
Johnston et al. ⁷	1974	298	200–360
Graham ²	1975	298	205–310
Yao et al. ¹⁴	1982	225, 243, 263, 277	290–380
Yao et al. ¹⁴	1982	298-300	200–380
Harwood et al. ⁵	1992	273, 295	280–380
Harwood et al. ⁴	1993	233–295	240–420
Harwood et al. ³	1998	295	208–398
Osborne et al. ¹¹	2000	195	152–240

Photolysis Quantum Yield and Product Studies: There are several studies of N₂O₅ primary photolysis products for wavelengths between 248 and 352.5 nm as summarized in Table 4C-7-3. The NO₃ radical is produced with unity quantum yield at wavelengths >300 nm. At shorter wavelengths the NO₃ quantum yield decreases to a value of ~0.71 at 248 nm and the O(³P) atom quantum increases. The study of Oh et al.¹⁰ indicates that the primary photolysis products other than NO₃ are a wavelength dependent mixture of NO₂, NO₂* and NO + O, where NO₂* represents electronically excited NO₂ that is most likely the ²B₁ state. For atmospheric model calculations unit photolysis quantum yields of NO₃ and NO₂ are recommended for wavelengths >300 nm.

C8. HONO (nitrous acid)

[Back to Index](#)

(Recommendation: 06-2; Note: 10-6; Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of nitrous acid, HONO, consists of a highly structured absorption band between 300 and 400 nm due to vibrational progressions in the $A^1A'' \leftarrow X^1A'$ transition, with a maximum intensity near 354 nm and a stronger continuous absorption band at shorter wavelengths with a maximum near 205 nm. A summary of the HONO room temperature absorption cross section studies for the near UV band is given in Table 4C-8-1.

Table 4C-8-1. Summary of HONO Absorption Cross Section Studies

Study	Year	Wavelength Range (nm)	Resolution (nm)	$10^{20} \sigma$ (354 nm) (cm ²)
Johnston and Graham ⁸	1974	300–399	0.87	12.3
Cox and Derwent ⁵	1976	200–394	<0.1	56.0
Perner ¹²	1977	310–388	0.6	55.2
Stockwell and Calvert ¹³	1978	310–396	<1	49.6
Platt et al. ¹¹	1980	336–376	0.8	47
Kenner et al. ⁹	1986	184–274	0.38	—
Vasudev ¹⁵	1990	310–393	—	(49.7)*
Bongartz et al. ³	1991	300–400	0.1 ($\lambda < 375$ nm) 0.8 ($\lambda < 375$ nm)	64.2**
Bongartz et al. ²	1994	300–400	0.1 ($\lambda < 375$ nm) 0.8 ($\lambda < 375$ nm)	54.9**
Febo et al. ⁶	1996	50–380	1	49.7**
Pagsberg et al. ¹⁰	1997	348–376	0.06	50.2
Brust et al. ⁴	2000	323–394	0.5	38.9
Stutz et al. ¹⁴	2000	291–404	0.061 ± 0.003	52.2
Wang and Zhang ¹⁶	2000	352.2 354.2 357.0	<0.1	48.9
Gratien et al. ⁷	2009	300–400	0.18	—

Notes:

* Normalized to the spectrum of Stockwell and Calvert¹³

** Bongartz et al.² corrected their 1991 results by a factor of 0.855

There is good agreement among the various data sets for the peak positions and discrepancies in the peak cross sections are generally a consequence of the differences in measurement spectral resolution. Stutz et al.¹⁴ normalized the cross section data from earlier studies to a resolution of 1 nm, resulting in an agreement of better than 10% between their results and those of Bongartz et al.,² Pagsberg et al.,¹⁰ and Vasudev.¹⁵ The measurements of Stockwell and Calvert¹³ are in reasonable agreement with the more recent studies. The cross sections from Cox and Derwent⁵ are greater by ~26% (presumably due to uncorrected NO₂ absorption) and those from Johnston and Graham⁸ are less by 70% (presumably due to non-equilibrium of the NO/NO₂/H₂O mixture during the measurement) than the more recent studies. The source of the discrepancy with the measurements of Brust et al.⁴ is unknown. Gratien et al.⁷ performed simultaneous measurements of HONO absorption spectra in the IR and UV and confirmed that the UV cross sections of Bongartz et al.² and Stutz et al.¹⁴ are consistent to within 5% with independent infrared studies and that the UV cross sections of Brust et al.⁴ are underestimated by ~22%.

The short wavelength absorption band was measured by Cox and Derwent⁵ (200–300 nm, <0.1 nm resolution) and Kenner et al.⁹ (184–274 nm, 0.38 nm resolution). The reported spectra are in quantitative agreement over the wavelength range 220–270 nm. The sharp peak at 215 nm reported by Cox and Derwent⁵, however, was not observed by Kenner et al.,⁹ who provide a number of arguments for the correctness of their results.

The recommended absorption cross sections in Table 4C-8-2 are a combination of data as follows: for the wavelength region 184–274 nm data was taken from Kenner et al.⁹ as read from a figure in their paper; for the wavelength region 296–396 nm data was taken from Stutz et al.,¹⁴ for the wavelength regions 296–325 nm and

371–396 nm averages over 1 nm intervals of the Stutz et al.¹⁴ high resolution spectrum are reported; and for the highly structured region 326–370 nm averages over 0.5 nm intervals were used.

Photolysis Quantum Yield and Product Studies: The photolysis quantum yield of HONO at wavelengths above the dissociation threshold are unity. The OH radical quantum yield at 365 ± 5 nm was determined by Cox and Derwent⁵ to be (0.92 ± 0.16) . Wollenhaupt et al.¹⁷ determined an upper limit of 0.01 for the quantum yield of H atom formation for photolysis at 351 nm. The OH(A) quantum yield from HONO laser photolysis at 193 nm was measured to be 1.8×10^{-5} by Kenner et al.⁹ The H + NO₂ (X²A₁, A²B₂, B²B₁, C²A₂) product channels in the photodissociation of HONO at 193.3 nm were examined by Amaral et al.¹ and branching ratios of the NO₂ electronic states estimated to be X²A₁ : A²B₂ : B²B₁/C²A₂ $\approx$ 0.13 : 0.21 : 0.66, respectively.

(Recommendation: 06-2; Note: 15-10; Evaluated: 15-10)

Absorption Cross Sections: The UV absorption spectrum of nitric acid, HNO_3 , consists of a strong absorption band between 150 and 240 nm with the maximum near 183 nm and a second band near 270 nm that appears as a shoulder on the long wavelength wing of the strong band. The recommended absorption cross sections and their temperature dependence for the region 192–350 nm listed in Table 4C-9 are taken from the work of Burkholder et al.³ The temperature effect is very important for estimates of atmospheric photodissociation rate coefficients. The results of Burkholder et al.³ agree well (to within 10% above 200 nm) with those of Rattigan et al.^{15,16} at room temperature, whereas Rattigan et al.^{15,16} report significantly smaller cross section values at 239 K (15–30% smaller in the range 220–330 nm and ~50% smaller at 330 nm). The recommended room temperature absorption cross sections are also in very good agreement with the data of Molina and Molina¹² (<15% difference up to 310 nm) and in good agreement with the values reported by Biaueme¹ and Johnston and Graham,⁸ except at long wavelength. Okabe¹⁴ reported cross sections in the 110–190 nm range that are 20–30% lower than those of Burkholder et al.,³ Biaueme,¹ and Johnston and Graham⁸ in the region 185–190 nm. Suto and Lee¹⁹ reported cross sections between 105 and 210 nm that are 10–20% higher than those of Burkholder et al.,³ Biaueme,¹ and Johnston and Graham⁸ in the region 185–190 nm, but show excellent agreement with the results of Molina and Molina¹² above 185 nm and Burkholder et al.³ above 189 nm.

On the basis of the results from the Biaueme, Burkholder et al., Johnston and Graham, and Rattigan et al. studies, uncertainty factors for the HNO_3 room temperature absorption cross sections in the wavelength regions 190–200 nm, 205–330 nm, and 335–350 nm are 1.1, 1.06, and 1.2 (2σ), respectively. The uncertainty factors at temperatures <298 K are expected to be greater in the 335–350 nm region, but are difficult to estimate without additional studies.

Photolysis Quantum Yield and Product Studies: There have been a number of room temperature HNO_3 photolysis studies conducted at wavelengths between 193 and 320 nm from which quantum yields have been derived. On the basis of end-product analysis, Johnston et al.⁷ reported a quantum yield of ~1 for the OH + NO_2 channel in the 200–315 nm range. Margitan and Watson¹¹ used atomic resonance fluorescence to determine the quantum yield for O atom production at 266 nm to be 0.03 and that for H atom production to be ≤ 0.002 . Jolly et al.⁹ measured a quantum yield for OH production of 0.89 ± 0.08 at 222 nm. Turnipseed et al.²⁰ reported OH quantum yields of (0.95 ± 0.09) at 248, (0.90 ± 0.11) at 222 nm, and 0.33 ± 0.06 at 193 nm. Turnipseed et al.²⁰ also reported quantum yields for production of O atoms, $\text{O}(^3\text{P}) + \text{O}(^1\text{D})$, to be 0.031 ± 0.01 , 0.20 ± 0.03 and 0.81 ± 0.13 at 248, 222, and 193 nm, respectively. Both $\text{O}(^3\text{P})$ and $\text{O}(^1\text{D})$ atom formation was observed at 222 and 193 nm but only $\text{O}(^3\text{P})$ was detected at 248 nm. At 193 and 222 nm the $\text{O}(^1\text{D})$ yield was determined to be 40% of the total O atom yield, yielding $\Phi(\text{O}(^1\text{D})) = 0.28 \pm 0.07$ at 193 nm. Turnipseed et al.²⁰ reported upper limits for $\Phi(\text{H}(^2\text{S}))$ of ≤ 0.002 at 238 nm, ≤ 0.01 at 222 nm, and ≤ 0.012 at 193 nm. Riffault et al.¹⁷ reported $\Phi(\text{OH})$ values of 0.88 ± 0.09 at 248 nm and 1.05 ± 0.29 at 308 nm. Schiffman et al.¹⁸ reported $\Phi(\text{OH}) = 0.47 \pm 0.06$ at 193 nm, which is larger than the value reported by Turnipseed et al.²⁰ At 248 nm they report $\Phi(\text{OH}) = 0.75 \pm 0.10$, which is a smaller value than reported in other studies.

Felder et al.⁶ used molecular beam/photofragment translational spectroscopy and reported the yield for (OH + NO_2) to be $\Phi(\text{OH}) = 0.6 \pm 0.1$ and for (O + HONO) to be $\Phi(\text{HONO}) = 0.4 \pm 0.1$ at 193 nm. Myers et al.¹³ also used this technique to measure the primary processes in the photolysis at 193 nm from the different photofragment ions and found evidence for all channels except 4. They determined the branching ratio (OH + NO_2)/(O+HONO) to be 0.50 ± 0.05 , $\Phi(\text{OH}) = 0.33 \pm 0.04$ (in excellent agreement with the value obtained by Turnipseed et al.²⁰). They also reported $\Phi(\text{O}(^3\text{P}) + \text{O}(^1\text{D})) = 0.67 \pm 0.04$, which is lower than the 0.81 ± 0.13 value reported by Turnipseed et al.²⁰ but the latter authors included the contribution of the secondary dissociation of NO_2 produced in channel (1). Their primary yield of $\text{O}(^1\text{D})$ formation of 0.54 ± 0.04 is much larger than the $\Phi(\text{O}(^1\text{D}))$ yield of 0.28 ± 0.07 measured by Turnipseed et al.²⁰ and this discrepancy remains unexplained. In a study using LIF and REMPI-TOF techniques, Li et al.¹⁰ found evidence for the ($\text{O}(^3\text{P}) + \text{HONO}$) channel with a yield of ~0.06.

Band strengths for the OH stretch vibrational overtones of HNO_3 have been reported by Donaldson et al.,⁵ Zhang et al.,²¹ and Brown et al.² Photodissociation of HNO_3 by excitation of the $3\nu_{\text{OH}}$ (~983 nm), $4\nu_{\text{OH}}$ (~755 nm) and $5\nu_{\text{OH}}$ (~618 nm) overtones is a possible source of atmospheric OH radicals. There is good agreement among the various studies. Band strengths (in units of $10^{-20} \text{ cm}^2 \text{ molecule}^{-1} \text{ cm}^{-1}$) of 2.63 for $3\nu_{\text{OH}}$ and 0.237 for $4\nu_{\text{OH}}$ were reported by Donaldson et al.⁵ Zhang et al.²¹ obtained band strengths of (2.9 ± 0.7) for $3\nu_{\text{OH}}$ and (0.28 ± 0.10) for $4\nu_{\text{OH}}$. Brown et al.² measured the band strengths for $4\nu_{\text{OH}}$ to be (0.225 ± 0.015) at 296 K and (0.223 ± 0.015) at 251 K and for $5\nu_{\text{OH}}$ to be (0.0257 ± 0.015) at 296 K and (0.0241 ± 0.035) at 251 K. Although the contribution to the overall atmospheric OH production rate from HNO_3 overtone photodissociation is small, it is larger than estimated by Donaldson et al.⁴

(Recommendation: 06-2; Note: 15-10; Evaluated: 15-10)

Absorption Cross Sections: The gas-phase UV absorption spectrum of peroxynitric acid, HO₂NO₂, has been reported by Cox and Patrick¹ (195–265 nm; 284 K), Morel et al.⁹ (200–290 nm; 298 K), Graham et al.³ (190–330 nm; 269 K), Molina and Molina⁸ (190–330 nm; 298 K), Singer et al.¹³ (210–329 nm; 253, 273, and 298 K), and Knight et al.⁵ (220–350 nm; 273, 296, 318, and 343 K). There is very good agreement (to within 5%) between the results of Molina and Molina⁸ and Singer et al.¹³ over the range 210–290 nm, but differences of ~15–60% exist in the wavelength range critical for atmospheric photodissociation (λ ≥ 290 nm). The cross section values from Cox and Patrick,¹ Graham et al.,³ and Morel et al.⁹ are systematically greater than those of Molina and Molina⁸ at wavelengths >200 nm. Knight et al.⁵ used the data of Molina and Molina⁸ and Singer et al.¹³ in the 250–270 nm region for normalization to provide absolute cross section data for the long wavelength region. The recommended room temperature absorption cross section data in Table 4C-10-1 are a combination of data from Molina and Molina⁸ in the region 190–205 nm, the mean of the data from Molina

and Molina⁸ and Singer et al.¹³ in the region 210–275 nm, and the data from Knight et al.⁵ in the region 280–350 nm.

The temperature dependence of the absorption spectrum was examined by Singer et al.,¹³ who found no temperature dependence between 253 and 298 K, and by Knight et al.,⁵ who reported a systematic increase of the absorption cross sections with increasing temperature. Knight et al.⁵ parameterized the temperature dependence using a two component model

$$\sigma(T, \lambda) = \sigma_0(\lambda)/Q + \sigma_1(\lambda) (1-1/Q)$$

where the partition function is given by $Q = 1 + \exp(-\Delta E/(0.69T))$ with $\Delta E = 988 \text{ cm}^{-1}$ (O-O stretching vibration) and T is in K. The Knight et al. parameterization is recommended.

On the basis of the results from the Molina and Molina, Singer et al., and Knight et al. studies, an uncertainty factor for the HO₂NO₂ room temperature absorption cross sections in the wavelength region 190–350 nm, is estimated to be 1.2 (2σ). The uncertainty factor at temperatures <298 K is expected to be greater in the long wavelength region, but is difficult to estimate without additional studies.

Photolysis Quantum Yield and Product Studies: HO₂NO₂ photodissociates in the UV with a unit quantum yield. MacLeod et al.⁶ measured the quantum yield of OH radicals at 248 nm as $\Phi(\text{OH}) = 0.34 \pm 0.16$ (the sum of channels 2 and 5), relative to the OH yield in the photolysis of H₂O₂. Roehl et al.¹⁰ determined the quantum yield of NO₂ in the photolysis at 248 nm (relative to the NO₂ yield in the photolysis of HNO₃) to be $\Phi(\text{NO}_2) = 0.56 \pm 0.17$ (the sum of channels 1,4 and 5). Jimenez et al.⁴ measured the yield of OH and HO₂ (from channels 1 and 6) at 193 and 248 nm (relative to the photolysis of H₂O₂) and the yield of NO₃ (relative to the photolysis of ClONO₂) at 193, 248 and 308 nm over a pressure range of 10 to 84 Torr. Jimenez et al.⁴ reported $\Phi_{193}(\text{OH}) = 0.21 \pm 0.12$, $\Phi_{248}(\text{OH}) = 0.085 \pm 0.08$, $\Phi_{193}(\text{HO}_2) = 0.56 \pm 0.02$, $\Phi_{248}(\text{HO}_2) = 0.89 \pm 0.26$, $\Phi_{193}(\text{NO}_3) = 0.35 \pm 0.03$, $\Phi_{248}(\text{NO}_3) = 0.08 \pm 0.03$ and $\Phi_{308}(\text{NO}_3) = 0.05 \pm 0.02$. Assuming that only channel (2) contributes to OH and NO₃ production, these results imply that at 248 nm the yields of OH and NO₃ are nearly identical, 0.08. This lower yield is in disagreement with the earlier 248 nm results of MacLeod et al.⁶ and Roehl et al.¹⁰ The high HO₂ yield (0.89 ± 0.26) measured at 248 nm by Jimenez et al.⁴ overlaps within the experimental uncertainties with the NO₂ yield (0.56 ± 0.17) of Roehl et al.,¹⁰ assuming that the HO₂ arises from channel (1). It cannot however not be excluded that the difference in NO₂ yields reflects the contribution of channel (6). The recommended quantum yields are given in Table 4C-10-2 where the values below 200 nm are taken from Jimenez et al.⁴ and the values above 200 nm represent an average of the results from Jimenez et al., Roehl et al. and MacLeod et al. The estimated uncertainty in the recommended quantum yields is ± 0.2 .

The photodissociation of HO₂NO₂ via excitation of the OH stretch vibrational overtones $2\nu_1$, $3\nu_1$, and $4\nu_1$ in the near IR and visible is a possible atmospheric HO_x source.^{15 12 2} The band strengths (in units of $10^{-20} \text{ cm}^2 \text{ molecule}^{-1} \text{ cm}^{-1}$) of (3.8 ± 0.11) for $3\nu_1$ and (0.30 ± 0.18) for $4\nu_1$ have been reported by Zhang et al.¹⁶ and (3.3 ± 0.7) for $3\nu_1$ by Roehl et al.¹¹ Stark et al.¹⁴ report greater values for the $3\nu_1$ and $4\nu_1$ band strengths of (5.7 ± 1.1) and (0.49 ± 0.09) , respectively. Roehl et al.¹¹ also measured absolute integrated band strengths and photodissociation quantum yields for 3 dissociative bands in the infrared region: $2\nu_1 + \nu_3$ (8242 cm^{-1}), $2\nu_1$ (6900 cm^{-1}) and $\nu_1 + 2\nu_3$ (6252 cm^{-1}) as a function of temperature. Matthews et al.⁷ photolysed HO₂NO₂ at 390 nm in its first OH-stretching overtone ($2\nu_1$) and reported a quantum yield of 0.30 at 298 K. The temperature dependent cross sections and dissociation quantum yields from Roehl et al.¹¹ are summarized in Table 4C-10-3.

SECTION 4D. ORGANIC PHOTOCHEMISTRY

D1. CH₃ (methyl radical)

[Back to Index](#)

(New)

Absorption Cross Sections: UV absorption cross sections of CH₃ (methyl radical) have been measured at room temperature by Adachi et al.¹ (215.2–217.0 nm, graphical data), Basco et al.² (216.4 nm), Cameron et al.³ (216.4 nm; 200–240 nm, graphical data), Khamaganov et al.⁴ (214.4–218.6 nm), MacPherson et al.⁵ (216.36 nm), Parkes and Quinn⁶ (216.5 nm), and Slagle et al.⁷ (216.36 nm). There are no reported measurements below room temperature, but several absorption measurements have been obtained of shock-heated methyl radicals at much higher temperatures (up to 2510 K).

The methyl radical has a narrow absorption band centered at 216.4 nm (~2 nm fwhm). All 7 room temperature studies agree to within 16% near the absorption peak. Of the studies that report data over a range of wavelengths, the shape of the absorption band differs significantly in the studies of Khamaganov et al. and Cameron et al., which Khamaganov et al. attribute to the lower spectral resolution of the Cameron et al. study (0.5 and 1.2 nm, respectively). The spectrum of Adachi et al. is blue shifted by ~0.2 nm relative to the studies of Khamaganov et al. and Cameron et al. The recommended cross section given in Table 4D-1 is for the absorption peak at 216.4 nm and is based on an average of all 7 studies. The recommended uncertainty factor (2σ) is 1.15.

Photolysis Quantum Yield and Product Studies: No recommendation.

Table 4D-1. Recommended Absorption Cross Section of CH₃ (methyl radical) at 298 K

λ (nm)	10 ²⁰ σ (cm ²)

D2. CH₄ (methane)

[Back to Index](#)

(1)

(Recommendation: 15-10; Note: 15-10; Evaluated: 15-10)

Absorption Cross Sections. CH₄ (methane) has negligible UV absorption. Its VUV absorption spectrum has been extensively studied at and around Lyman- α , 121.567 nm, including studies by Watanabe et al.¹⁵ (120–144 nm), Ditchburn⁶ (27–151 nm), Sun and Weissler¹³ (37–131 nm), Laufer and McNesby⁹ (113–143 nm), Backx et al.² (13.8–144 nm), Mount et al.¹² (137–160 nm), Lee and Chiang¹¹ (106–142 nm), Lee et al.¹⁰ (120–153 nm), Au et al.¹ (5.6–165 nm), Brownsword et al.³ (121.6 nm), Vatsa and Volpp¹⁴ (121.567 nm), Kameta et al.⁷ (52–125 nm), and Chen and Wu⁵ (120–142 nm). The measured, or interpolated, values are in reasonable agreement at 121.567 nm, to within 20%. The recommended Lyman- α cross section at 298 K, adopted from Chapter 3⁴ in the SPARC⁸ (2013) lifetime report, is $1.85 \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$ with an uncertainty factor of 1.3 (2σ).

D3. CH₂O (formaldehyde)

[Back to Index](#)

CH ₂ O + hν	→ H + HCO	363 kJ mol ⁻¹	330 nm	(1)
	→ H ₂ + CO	331 kJ mol ⁻¹	361 nm	(2)
	→ H + H + CO	423 kJ mol ⁻¹	283 nm	(3)

(Recommendation: 15-10, Note: 15-10, Evaluated: 15-10)

Absorption Cross Sections. The UV absorption spectrum of formaldehyde (CH₂O) displays a highly structured absorption band (the formally electric-dipole forbidden S₁ ← S₀ transition gives rise to the $\tilde{A}^1A_2 - X^1A_1$ band system, which becomes allowed through vibronic coupling) between 240 and 380 nm. The absorption spectrum of formaldehyde has been measured in many studies at temperatures between 222 and 353 K as summarized in Table 4D-3-1.

Table 4D-3-1. Summary of CH₂O Absorption Cross Section Studies

Study	Year	Temperature (K)	Wavelength range (nm)	Resolution (nm)	Medium
McMillan ⁵	1966	348	202–374	1	air
McQuigg and Calvert ²²	1969	300	220–370	1	air

Pope et al. ²⁹	2005	263, 294	313–320	0.1 cm ⁻¹ (~0.001)	air/vacuum
Pope et al. ³⁰	2005	294	308–320	0.1 cm ⁻¹	air/vacuum
Co et al. ¹¹	2005	220, 298	351–356	0.0003	vacuum
Smith et al. ³²	2006	245, 294	300–340	0.0035	air/vacuum
Gratien et al. ¹⁷	2007	296	240–370	0.15	air
Gratien et al. ¹⁸	2007	294	300–360	0.18	air
Gorrotxategi Carbajo et al. ¹⁶	2008	245, 294	300–330	0.0035	air/vacuum
Tatum Ernst et al. ³⁵	2012	294 ± 2	304–330	0.09 cm ⁻¹ (~0.001)	air

Meller and Moortgat²³ have reviewed the cross section studies prior to 2000 including descriptions of the techniques, experimental details of CH₂O generation and the absorption measurements, and a comparison of the various results. The CH₂O absorption cross sections are a strong function of the measurement resolution and this needs to be considered when comparing results from the various studies. Low resolution spectra were obtained by McMillan⁵ and Moortgat et al.²⁵ whereas medium resolution measurements were reported by Bass et al.,¹ Rogers,³¹ and Bogumil et al.² The spectrum reported by Cantrell et al.⁶ was measured with a resolution of 0.011 nm over the 300–358 nm region in the temperature range 223–293 K using Fourier transform spectroscopy. Meller and Moortgat²³ reported a spectrum at ~0.025 nm resolution over the entire UV absorption band (224–373 nm) at 298 and 223 K using diode array spectroscopy. In general, the agreement between the medium and higher resolution data is good, although the cross section data of Bass et al.¹ and Rogers³¹ are systematically lower than those of Meller and Moortgat²³. The spectrum reported by Bogumil et al.² that was obtained using the SCIAMACHY pre-flight satellite instrument agrees with the data of Meller and Moortgat.²³ The low resolution absorption cross sections reported by Chen and Zhu^{7,8} and Chen et al.⁹ in the 280–330 nm region deviate substantially, up to 50%, from those reported by Meller and Moortgat.²³

A high resolution CH₂O spectrum, near the Doppler broadening limit of 0.07 cm⁻¹, was measured by Pope et al.^{29,30} in the range 308–320 nm using tunable UV laser absorption spectroscopy at 263 and 294 K. In a later study from the same laboratory, Smith et al.³² extended the high resolution measurements (0.35 cm⁻¹) from 300 to 340 nm at 294 and 245 K. The high resolution CH₂O spectrum measured by Pope et al.^{29,30} is in excellent

agreement with the spectral features reported by Cantrell et al.⁶ and Meller and Moortgat²³ after convolution with the lower resolution instrument functions. Rotationally resolved absorption cross sections in the narrow spectral region 351–356 nm were measured by Co et al.¹¹ using Fourier Transform spectroscopy with an apodized resolution of 0.027 cm⁻¹. They observed a strong pressure dependence of the rotational lines over the pressure range 75 to 400 Torr and determined a pressure broadening coefficient in dry air of 1.8×10^{-4} cm⁻¹ Torr⁻¹ for several isolated lines in the 2⁰₀4¹₀ band.

Gratien et al.^{17,18} measured UV (0.15 nm resolution) and IR absorption cross sections simultaneously and compared the Integrated Band Intensities (IBI) of the main vibronic bands with previously published UV and IR data. The IBIs measured by Gratien et al.¹⁸ in the region 300–360 nm compare well (within ~7%) with the IBI data derived from Meller and Moortgat,²³ but are ~20% lower than the IBIs calculated from the Cantrell et al.⁶ and Rogers³¹ data. Gratien et al.¹⁸ attribute the difference to the IR band strength given in the HITRAN database, which is based on the data from Cantrell et al.⁶ In a second study, Gratien et al.¹⁷ compared the IBIs of 9 different band sections in the 300 to 360 nm region with more recent studies. In general, the IBI data of Gratien et al.¹⁷ are in excellent agreement (within 2%) with the high resolution results of Smith et al.³² It was also shown that the IBI data for 8 band sections measured by Smith et al.³² are 2 to 14% larger than the data of Meller and Moortgat.²³ The IBIs for the bands studied by Pope et al.^{29,30} (313.5–316.5 and 316.5–319.7 nm) are 4 and 13% larger, respectively, than the data of Meller and Moortgat.²³ On the other hand the IBI for the 351.7–355.5 nm band studied by Co et al.¹¹ is 12% larger than the values of Cantrell et al.⁶ and Rogers,³¹ but in excellent agreement with those of Meller and Moortgat²³ and Gratien et al.¹⁷

The study by Tatum Ernst et al.³⁵ used tunable UV laser absorption to measure the CH₂O spectrum at high resolution (0.09 cm⁻¹) over the wavelength range 304–330 nm at 294 K. Significant differences exist in the resolved line peak heights and depth between lines obtained in this study and the high resolution studies of Pope et al.,^{29,30} and Smith et al.³² (the Tatum Ernst et al. dataset shows greater spectrum structure). This leads to discrepancies in the band strengths between this work and previous high resolution studies that is not presently understood. Tatum Ernst et al.³⁵ estimate the cross section uncertainty in their study to be ~10% (1σ).

In general, the consistency between the absorption cross section data of Smith et al.,³² Gratien et al.,¹⁷ and Pope et al.^{29,30} in the range 300 to 360 nm demonstrate that the previously recommended absorption cross sections reported by Meller and Moortgat²³ are too low by about 7–10%. The presently recommended cross sections in Table 4D-3-2 were taken from Meller and Moortgat²³ averaged over 1 nm intervals and scaled up by 8%. Table 4D-3-3 includes the scaled data averaged over intervals used in atmospheric modeling. Higher resolution cross section data can be obtained from the (studies cited in Table 4D-3-1). The estimated cross section uncertainty is expected to be a function of wavelength and measurement resolution. The recommended uncertainty factor for the band strengths is estimated to be 1.1 (2σ).

The temperature dependence of the CH₂O absorption cross sections has been studied by Bass et al.,¹ Moortgat et al.,²⁵ Cantrell et al.,⁶ Meller and Moortgat,²³ Pope et al.,^{29,30} Co et al.,¹¹ and Smith et al.³² (see Table 4D-3-1). Temperature effects are the strongest at the maximum of the absorption bands where the lower temperatures result in larger absorptions. This effect is reversed in the wings of the absorption bands where higher temperatures result in a higher absorption. A linear parameterization of the absorption cross section temperature dependence between 223 and 323 K was derived by Meller and Moortgat:²³

$$\sigma(\lambda, T) = \sigma(\lambda, 298 \text{ K}) + \Gamma(\lambda) \times (T - 298)$$

Values of $\Gamma(\lambda)$ from Meller and Moortgat²³ were scaled up by 8% and the values averaged over 1 nm intervals and intervals used in atmospheric modeling are listed in Table 4D-3-2 and Table 4D-3-3, respectively.

VUV absorption cross sections for the wavelength region 60–185 nm have been obtained by Gentieu and Mentall,¹⁴ Mentall et al.,²⁴ and Glicker and Stief¹⁵ using optical methods and by Cooper et al.¹² for the region 6–261 nm using (e,e) dipole spectroscopy.

Photolysis Quantum Yields and Product Studies: The quantum yield studies by McQuigg et al.²² and Calvert et al.⁴ established that over the wavelength range 290–360 nm the radical yield increases with decreasing wavelength. More precise wavelength dependent quantum yield studies using monochromatic light sources were performed by Lewis et al.,²⁰ Marling,²¹ Horowitz and Calvert,¹⁹ Clark et al.,¹⁰ Moortgat et al.,²⁷ and Tang et al.³⁴ Moortgat and Warneck²⁸ and Moortgat et al.^{25,26} measured the yields of CO and H₂ in air (giving $\Phi_1(\text{H} + \text{HCO}) + \Phi_2(\text{H}_2 + \text{CO})$ and $\Phi_2(\text{H}_2 + \text{CO})$) as a function of wavelength (253–353 nm) and pressure (380–800 Torr) at 300 K and 220 K. These studies showed that the yield of CO was essentially unity between 290 and 330 nm at all pressures with no systematic temperature dependence. For $\lambda > 330$ nm, both temperature and pressure have a significant effect on $\Phi_2(\text{H}_2 + \text{CO})$ but a negligible effect on $\Phi_1(\text{H} + \text{HCO})$. At $\lambda < 290$ nm the total CO yield was found to decrease to a value of 0.76 at 240 nm.

Smith et al.³³ measured relative quantum yields at 50 mbar for the production of the radical products H and HCO using NO-chemical amplification and subsequent detection of NO₂ with chemical ionization mass spectrometry. These authors measured the quantum yields in the range 269 to 339 nm with sufficient resolution (± 0.62 nm) to observe structure in the wavelength dependence, that was previously unreported, that is believed to provide evidence for a competition among the various dissociation pathways. The measured $\Phi_1(\text{H} + \text{HCO})$ yields were normalized to a value of 0.753 at 303.75 nm based on the NASA/JPL 97-4 recommendation¹³ and agree with the previous determinations reported by Horowitz and Calvert¹⁹ and Moortgat et al.²⁶ However at $\lambda > 320$ nm the $\Phi_1(\text{H} + \text{HCO})$ yields reported by Smith et al.³³ are larger than the values recommended by DeMore et al.¹³ resulting in a larger ($\sim 8\%$) overall rate of radical production.

Pope et al.^{29,30} and Gorrotxategi Carbajo et al.¹⁶ used cavity ring-down spectroscopy to measure HCO radical absorption coefficients and CH₂O absorption cross sections from which absolute HCO quantum yields were calculated. The absolute HCO radical signal was calibrated against the HCO radical produced from the $\text{Cl} + \text{HCHO} \rightarrow \text{HCO} + \text{Cl}_2$ reaction following the photolysis of $\text{Cl}_2/\text{CH}_2\text{O}/\text{N}_2$ mixtures. In the 303–309 nm range $\Phi_{\text{HCO}} \sim 0.6 \pm 0.1$ was obtained, which is 25% lower than the NASA/JPL 06-2 recommendation and the data reported by Smith et al.³³ In the wavelength range 314–330 nm the Φ_{HCO} values (0.06 to 0.11) agree to within the quoted uncertainties with the NASA/JPL 06-2 recommendation.

The experimental technique used by Gorrotxategi Carbajo et al.¹⁶ measured the product of the high resolution absolute absorption cross section (identical as measured by Smith et al.³²) and the absolute HCO quantum yield, $\Phi_{\text{HCO}}(\lambda)\sigma_{\text{CH}_2\text{O}}(\lambda)$, in the interval 302.6–331.0 nm with a wavelength resolution of 0.005 nm. It is important to note that a separate calculation of the product $\Phi_{\text{HCO}}\sigma_{\text{CH}_2\text{O}}$ using single data of Φ_{HCO} and $\sigma_{\text{CH}_2\text{O}}$ at a given wavelength result in much lower $\Phi_{\text{HCO}}\sigma_{\text{CH}_2\text{O}}$ values (up to a factor 2) than obtained by the direct combined technique.

Tatum Ernst et al.³⁶ used pulsed laser photolysis combined with pulsed laser induced fluorescence detection of OH radicals (conversion of $\text{H} + \text{HCO}$ to OH by reaction with NO₂) to determine a high resolution action spectrum, i.e., the product of the CH₂O cross section and $\text{H} + \text{HCO}$ quantum yield, over the wavelength range 304 to 329 nm. $\Phi_1(\text{H} + \text{HCO})$ yields were determined using the CH₂O cross section data reported in Tatum Ernst et al.³⁶ and an absolute value of 0.69 at 31750 cm⁻¹. The quantum yields for the individual absorption bands in this region are in reasonable agreement with previous determinations and earlier NASA/JPL recommendations, although differences between individual absorption bands that were not noted in previous studies were reported.

Troe³⁷ used theoretical calculations to evaluate the quantum yields for the molecular and radical photolysis processes at $\lambda > 310$ nm. An analytical representation was provided that enables extrapolation into temperature and pressure ranges that are not easily accessible experimentally.

The recommended quantum yields at standard pressure (1 atmosphere) and 300 K are listed in Table 4D-2-4 are based on a polynomial fit over the wavelength range 250–338 nm of the data for $\Phi_1(\text{H} + \text{HCO})$ from Lewis et al.,²⁰ Marling,²¹ Horowitz and Calvert,¹⁹ Clark et al.,¹⁰ Tang et al.,³⁴ Moortgat et al.,²⁶ Smith et al.,³³ Pope et al.,^{29,30} Gorrotxategi Carbajo et al.,¹⁶ and Tatum Ernst et al.³⁶

$$\Phi_1(\text{H} + \text{HCO}) = a_0 + a_1\lambda + a_2\lambda^2 + a_3\lambda^3 + a_4\lambda^4$$

where

$$a_0 = 557.95835182$$

$$a_1 = -7.31994058026$$

$$a_2 = 0.03553521598$$

$$a_3 = -7.54849718 \times 10^{-5}$$

$$a_4 = 5.91001021 \times 10^{-8}$$

$\Phi_2(\text{H}_2 + \text{CO})$ was optimized using the quantum data for CO from Moortgat et al.²⁶ and the relation $\Phi_2(\text{H}_2 + \text{CO}) = \Phi_{\text{tot}} - \Phi_1(\text{H} + \text{HCO})$. The pressure and temperature dependence of $\Phi_2(\text{H}_2 + \text{CO})$ for wavelengths > 330 nm is based on the algorithm cited in Calvert et al.³ The pressure dependence of $\Phi_2(\text{H}_2 + \text{CO})$ is represented in Stern-Volmer form:

$$\Phi_2(\text{H}_2 + \text{CO}) = \left[\frac{1}{\frac{1}{(1 - \Phi_1(\lambda))} + \alpha(\lambda, T) \times P} \right]$$

where pressure, P, is in atmospheres and $\alpha(\lambda, T)$ is the quenching coefficient whose values at 300 K are calculated from Φ_1 and Φ_2 :

$$\alpha(\lambda, 300 \text{ K}) = \frac{1}{\Phi_2(\lambda, 300 \text{ K})} - \frac{1}{(1 - \Phi_1(\lambda))}$$

At temperatures between 220 and 300 K the quenching coefficient $\alpha(\lambda, T)$ can be calculated using:

$$\alpha(\lambda, T) = \alpha(\lambda, 300 \text{ K}) \times \left[1 + 0.05 \times (\lambda - 329) \times \left(\frac{(300 - T)}{80} \right) \right]$$

The formulae given above for the pressure and temperature dependence of the quantum yields are recommended.

D4. CH₂OO (formaldehyde oxide)

[Back to Index](#)

(Recommendation: 19-5; Note: 19-5; Evaluated: 19-5)

Absorption Cross Sections: UV absorption cross sections of the simplest Criegee intermediate CH₂OO (formaldehyde oxide) have been reported at room temperature by Beames et al.¹ (281–410 nm), Sheps et al.⁴ (295.156–449.421 nm), Buras et al.² (375 nm), Ting et al.⁵ (280–483.8 nm), and Foreman et al.³ (362–476 nm). The cross section values of Ting et al., Foreman et al., and Buras et al. are in good agreement at wavelengths less than 400 nm, and are substantially lower than the values of Beames et al. and Sheps et al. At wavelengths greater than 410 nm, the cross sections of Foreman et al. are significantly greater than those of Ting et al. The discrepancy is approximately a factor of 2 at 420 nm and increases at longer wavelengths.

Ting et al. used SO₂ scavenging and self-reaction of CH₂OO to measure the shape of the absorption spectrum and assigned absolute cross sections at 308.4 and 351.8 nm based on molecular beam laser-depletion measurements. Their use of a reference molecule to effectively calibrate the laser fluence leads to more accurate results relative to the estimated laser fluence (without correction for beam non-uniformity) used for the Beames et al. action spectrum. Ting et al. also postulate that a temperature dependence of the CH₂OO cross sections at wavelengths greater than 360 nm could explain why the Beames et al. spectrum is weaker there.

The recommended cross sections given in Table 4D-4 are from Ting et al. and are 5 nm averages of their data (reported every ~0.6 nm) between 285–350 nm, 1 nm averages between 350–425 nm, and 5 nm averages between 425–450 nm. The wavelength-dependent averaging serves to maintain the vibrational structure on the long wavelength side of the peak cross section, which can be important for spectroscopic identification.

Estimated uncertainty factors (2σ) are recommended to be 1.2 at wavelengths less than 400 nm and increase linearly to 3.0 at 450 nm, primarily due to the discrepancy with Foreman et al. Although cross section data exist out to 484 nm, no recommendation is made for wavelengths longer than 450 nm due to the large uncertainties.

Photolysis Quantum Yield and Product Studies: No recommendation.

Table 4D-4. Recommended Absorption Cross Sections of CH₂OO (formaldehyde oxide) at 295 K

λ (nm)	$10^{20} \sigma$ (cm ²)	λ (nm)	$10^{20} \sigma$ (cm ²)	λ (nm)	$10^{20} \sigma$ (cm ²)

D5. CH₃O₂ (methylperoxy radical)[Back to Index](#)

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption cross sections of the methylperoxy radical, CH₃O₂, in the 195–310 nm region have been measured at room temperature by Parkes et al.,²¹ Hochanadel et al.,⁸ Parkes,²⁰ Anastasi et al.,² Kan et al.,¹¹ Cox and Tyndall^{3,4} at 250 nm only; Adachi et al.,¹ Sander and Watson²⁴ at 250 nm only, Pilling and Smith²² at 254 nm only, Kurylo et al.,¹² McAdam et al.,¹⁷ Jenkin et al.,¹⁰ Wallington et al.,²⁷ Moortgat et al.,¹⁸ Dagaut and Kurylo,⁵ Simon et al.,²⁵ Jenkin and Cox,⁹ Lightfoot and Jemi-Alade¹⁴ who measured the cross sections up to 777 K, Maricq and Wallington,¹⁶ Wallington et al.,²⁹ Roehl et al.,²³ Fahr et al.,⁶ and Nielsen et al.¹⁹ The absorption cross sections have been evaluated in earlier reviews by Lightfoot et al.¹³ and Wallington et al.,²⁸ who noted significant discrepancies in both the shapes of the spectra and the absolute magnitude of the cross section values. The ultraviolet absorption spectra have recently been reevaluated by Tyndall et al.,²⁶ who fit the absorption spectra to a semi-logarithmic Gaussian distribution function suggested by Lightfoot et al.¹³ and Maric et al..¹⁵

$$\sigma = \sigma_{\text{max}} \exp \left[-a \left(\ln \left(\frac{\lambda_{\text{max}}}{\lambda} \right) \right)^2 \right]$$

Screening of the data suggested that most spectra published before 1987 did not constrain the shape of the spectrum very well as indicated by the large relative uncertainty of the width parameter *a*. The shape was determined by averaging the individual fitting parameters from McAdam et al.,¹⁷ Moortgat et al.,¹⁸ Simon et al.,²⁵ Lightfoot and Jemi-Alade,¹⁴ Jenkin and Cox,⁹ and Maricq and Wallington,¹⁶ which were judged to be most reliable by Tyndall et al.²⁶ Absolute cross sections were based on relative measurements of absorption cross sections of CH₃O₂ and C₂H₅O₂ at 240 nm taken under identical conditions (Wallington et al.,²⁸ Maricq and Wallington,¹⁶ Fenter et al.,⁷ and Roehl et al.²³), combined with independent calibrations by Dagaut and Kurylo,⁵ Simon et al.,²⁵ and Lightfoot and Jemi-Alade.¹⁴ The fit parameters are: $\sigma_{\text{max}} = 4.26 \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1}$; *a* = 44.4; $\lambda_{\text{max}} = 237.3 \text{ nm}$. Table 4D-5 lists the recommended cross sections, which are taken from the review by Tyndall et al.²⁶ The shape of the UV spectrum measured by Nielsen et al.¹⁹ is in excellent agreement with the recommendation of Tyndall et al.²⁶

Photolysis Quantum Yield and Product Studies: No recommendation. The loss of CH₃O₂ due to photolysis in the stratosphere and troposphere is expected to be negligible.

Table 4D-5. Recommended Absorption Cross Sections of CH₃O₂, C₂H₅O₂, and CH₃C(O)O₂ at 298 K

D6. CH₃OH (methanol, methyl alcohol)

[Back to Index](#)

(New)

Absorption Cross Sections: VUV/UV absorption cross sections of CH₃OH (methanol) have been measured at room temperature by Burton et al.¹ (15.5–207 nm), Cheng et al.² (107–219.5 nm), Dillon et al.³ (185 nm), Harrison et al.⁵ (161–197.1 nm, graphical data), Jiménez et al.⁶ (185 nm), Lange et al.⁷ (115–220.5 nm), Nee et al.⁸ (106.1–197.6 nm, graphical data), Ogawa and Cook⁹ (50.8–174.9 nm), Person and Nicole¹⁰ (105.25–124.35 nm, graphical data), Salahub and Sandorfy¹¹ (120–204.6 nm), and Tsubomura et al.¹² (164–185 nm, graphical data). Flowerday et al.⁴ have also reported very small absorption cross sections of CH₃OH in the visible region

(445–456 nm and 505–516 nm) at room temperature using a cavity-enhanced technique. The data of Cheng et al., Dillon et al., Harrison et al., Lange et al., Nee et al., and Salahub and Sandorfy are in good agreement between 165–192 nm. Over this same range, the studies of Burton et al., Ogawa and Cook, and Tsubomura et al. disagree substantially with other studies. At UV wavelengths >192 nm, fewer studies are available, and the cross section data generally diverge as wavelength increases.

For VUV data in the 110–165 nm range, the studies of Cheng et al., Harrison et al., Lange et al., Person and Nicole, and Salahub and Sandorfy are generally in good agreement. At wavelengths shorter than 110 nm, the data of Ogawa and Cook are consistently 10–20% higher than the cross sections of Burton et al.

The recommended cross sections given in Table 4D-6 for 166–219 nm are from Cheng et al. at 1 nm intervals, interpolated to integer wavelengths. For the range 220–230 nm, the recommended values were obtained from a log-linear fit (209–219 nm) and extrapolation of the Cheng et al. data, $\log \sigma(\lambda) = 10.5034 - 0.14807 \lambda$. Estimated uncertainty factors (2σ) of 1.1 for $\lambda = 166$ –192 nm, 1.2 for $\lambda = 193$ –208 nm, and 1.3 for $\lambda = 209$ –219 nm are recommended. The recommended Lyman- α (121.567 nm) cross section is an average of the data of Lange et al., Cheng et al., Person and Nicole, Salahub and Sandorfy, and Nee et al. and given an estimated uncertainty factor (2σ) of 1.05.

Photolysis Quantum Yield and Product Studies: No recommendation.

D7. CH₃OOH (methylhydroperoxide)

[Back to Index](#)

CH ₃ OOH + hν → CH ₃ O + OH	185 kJ mol ⁻¹	645 nm	(1)
→ CH ₃ + HO ₂	292 kJ mol ⁻¹	410 nm	(2)
→ CH ₃ O ₂ + H	358 kJ mol ⁻¹	334 nm	(3)
→ CH ₃ OH + O(³ P)	179 kJ mol ⁻¹	670 nm	(4)

(Recommendation: 10-6, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The absorption spectrum of CH₃OOH (methylhydroperoxide) was measured at room temperature by Cox and Tyndall² (210–280 nm), Nozière et al.⁵ (220–250 nm), Molina and Arguello⁴ (210–350 nm), Vaghjiani and Ravishankara⁸ (210–365 nm), Blitz et al.¹ (210–355 nm), Matthews et al.³ (365–405 nm), and Roehl et al.⁶ (305–365 nm).

Vaghjiani and Ravishankara⁸ measured the cross sections of CH₃OOH by monitoring the CH₃OOH concentration via trapping and titration. These results are recommended and are listed in Table 4D-7. The earlier results of Molina and Arguello⁴ are consistently 40% higher than the values shown in Table 4D-7. This difference is believed to be due to difficulty in trapping CH₃OOH and measuring its concentration. The results of Blitz et al.¹ are consistently 30% smaller than the data of Vaghjiani and Ravishankara⁸ in the range 225–325 nm and are unreliable above 325 nm due to baseline problems during their measurements. The absorption cross sections of Roehl et al.⁶ determined using action spectroscopy are 8-21 % greater than those measured by Vaghjiani and Ravishankara.⁸ Similar absorption measurements were performed by Matthews et al.³ in the weak tail of the absorption band up to 405 nm. Their cross sections were normalized to the value of Vaghjiani and Ravishankara⁸ at 355 nm and are included in the recommendation in Table 4D-7.

Matthews et al.³ also measured the absorption of the 5_{VOH} overtone band near 620 nm as $(3.6 \pm 0.4) \times 10^{-24}$ cm² molecule⁻¹.

Photolysis Quantum Yields and Product Studies: CH₃OOH dissociates to give CH₃O with unit quantum yield $\Phi_1 = 1.00 \pm 0.18$ (Vaghjiani and Ravishankara⁹). These authors also observed some production of H (quantum yield of 0.038 ± 0.007) and O atoms (quantum yield <0.007) at shorter wavelengths (i.e., 193 nm).

Thelen et al.⁷ report unit quantum yields for OH production at 248 and 193 nm that are in agreement with the results of Vaghjiani and Ravishankara.⁸ Quantum yields for OH and CH₃O were also measured by Blitz et al.¹ in the wavelength range 223–355 nm. These authors have shown that the quantum yield for both OH and CH₃O production is unity across this range of wavelengths.

Table 4D-7. Recommended Absorption Cross Sections of CH₃OOH at 298 K

→ H ₂ + CO ₂ + HCOOH	(8)

(Recommendation: 25-1, Note: 25-1, Evaluated: 25-1)

Absorption Cross Sections: The UV absorption spectrum of formic acid, HC(O)OH, and formic acid dimer, (HC(O)OH)₂, have been measured near 300 K for a range of sample pressures by McMillan² (200–249 nm; 35.2, 16.4, and 2.45 Torr), Singleton et al.¹⁰ (195–250 nm; 29 pressures between 0.5 and 22 Torr), Singleton et al.,¹² and Nagakura et al.⁸ (154–191 nm). Jolly et al.⁶ reported cross sections at 222 nm in connection with their quantum yield measurements. Singleton et al.¹² also measured spectra at 356.2 K. The absorption spectrum of the dimer has a broad maximum near 205 nm and a monotonic decrease in intensity with increasing wavelength. The absorption maximum of the monomer is shifted to longer wavelengths, with a peak cross section near 215 nm, about one third the magnitude of the peak cross section for the dimer. The decrease in cross sections with increasing wavelength is more rapid for the dimer than for the monomer, resulting in monomer cross sections being greater at 250 nm by approximately a factor 10. The absorption spectra reported by McMillan² were derived assuming monomers only in spite of undefined amounts of monomer and dimer contributions, resulting in a reported spectra that lies between those reported by Singleton et al.¹⁰ for the monomer and the dimer. The recommended absorption cross sections in Table 4D-8 are taken from Singleton et al.¹⁰ measured with a resolution of 1 nm.

The VUV spectrum of HC(O)OH has been measured by several groups.^{1,3,4,7,9,13} The recommended Lyman- α (121.567 nm) absorption cross section for HC(O)OH of 1.31×10^{-17} cm² molecule⁻¹ is an average of the measurements in this wavelength region by Suto et al.,¹³ Leach et al.,⁷ and Randi et al.⁹

Photolysis Quantum Yield and Product Studies: In the pre-1966 studies considered in Calvert and Pitts,² yields of final products CO, CO₂, H₂, H₂O (suggested as due to the molecular elimination channels 4 and 5) were determined. However, in the experiments considered it would be difficult to distinguish between primary photolytic products and products formed by subsequent secondary free-radical reactions. Jolly et al.⁶ determined the quantum yield of OH formation at 222 nm for the monomer to be 1.05 ± 0.14 and essentially zero for the dimer. In a follow-up study, Singleton et al.¹² re-determined the OH quantum yields at 222 nm to be 0.704 ± 0.048 at 298 K and 0.771 ± 0.030 at 356.2 K for the monomer, and 0.153 ± 0.028 at 298 K for the dimer (the OH yield for the dimer at elevated temperatures was assumed to be zero). Photodissociation into the other radical channels, 2 and 3, is minor and has been discussed by He and Fang.⁵ Photodissociation quantum yields for the dimer were determined at 222 nm by Singleton et al.¹¹ to be $\Phi_6 = 0.15$, $\Phi_7 = 0.81$ and $\Phi_8 = 0.04$.

D9. HC(O)OOH (peroxyformic acid, performic acid, PFA)

[Back to Index](#)

(Recommendation: 19-5; Note: 19-5; Evaluated: 19-5)

Absorption Cross Sections: UV absorption cross sections of HC(O)OOH (peroxyformic acid) have been reported at room temperature by Indulkar et al.¹ at 282 and 355 nm. The Indulkar et al. measurements are the only UV absorption data currently available for this molecule. The absorption cross sections in this study were estimated by comparing the OH yield from PFA to that from H₂O₂ for which the cross sections at 282 and 355 nm are known. Indulkar et al. used a Gaussian function to interpolate between the two measured points and estimated the absorption cross sections for PFA over the entire 282–355 nm range. The recommended cross sections given in Table 4D-9 are the 282 nm and 355 nm values from Indulkar et al. An estimated uncertainty factor (2σ) of 1.5 is recommended.

Photolysis Quantum Yield and Product Studies: The quantum yield for OH formation from PFA was assumed to be unity by Indulkar et al.¹ at 282 and 355 nm. At 282 nm, this assumption was based on molecular orbital calculations indicating that O–O bond breakage is dominant, and at 355 nm, the OH fragmentation channel is the only one energetically open.

Table 4D-9. Recommended Absorption Cross Sections of HC(O)OOH (peroxyformic acid) at 298 K

λ (nm)	10 ²⁰ σ (cm ²)
282	0.80
355	0.0034

D10. HOCH₂OOH (hydroxymethyl hydroperoxide)

[Back to Index](#)

(Recommendation: 10-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of hydroxymethyl hydroperoxide, HOCH₂OOH, was measured at 298 K by Bauerle and Moortgat¹ in the range 205–360 nm, using a combination of diode array and FTIR spectroscopy. The absorption cross sections were also determined via action spectroscopy of the OH product by Roehl et al.³ in the range 310–360 nm. The cross sections measured by Roehl et al.³ were normalized to the value of Bauerle and Moortgat¹ at 320 nm. Their values are in reasonable agreement (within 20%) between 310 and 340 nm but are lower than those of Bauerle and Moortgat¹ at longer wavelengths (e.g. 33%

at 350 nm). The recommended cross sections listed in Table 4D-10 are taken from Bauerle and Moortgat¹ in the range 205–305 nm, and from the average of the values of Bauerle and Moortgat¹ and Roehl et al.³ for the region 310–380 nm.

Photolysis Quantum Yields and Product Studies: The photolysis process is assumed to occur with unity quantum yield, Φ_1 , at wavelengths greater than 290 nm, in analogy with CH₃OOH. Overtone photodissociation spectrum and quantum yields were obtained in the OH-stretching region for the 4_{VOH} (centered at 750 and 738 nm for the OO–H and RO–H bands, respectively) and 5_{VOH} (centered at 617 and 604 nm for the OO–H and RO–H bands, respectively) transitions by Fry et al.² Overtone photodissociation is not expected to be significant under atmospheric conditions.

D11. CH₃CO (acetyl radical)[Back to Index](#)

(1)

(Recommendation: 10-6, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections. The UV absorption spectrum of the acetyl radical, CH₃CO, has been measured by Adachi et al.,^{1,2} Parkes,⁷ Anastasi and Maw,³ Basco and Parmar,⁴ Maricq and Szenté,⁶ and Cameron et al.⁵ The spectrum has a very broad band in the range 190–270 nm with maximum near 215 nm. The shapes and magnitudes of the reported spectra differ substantially in the different studies. Adachi et al.^{1,2} and Basco and Parmar⁴ report a peak cross section of 3.75×10^{-17} cm² molecule⁻¹ whereas Maricq and Szenté⁶ report a value of 1.07×10^{-17} cm² molecule⁻¹ at 216 nm and Ansatasi and Maw³ a value of 0.7×10^{-17} cm² molecule⁻¹ at 223 nm. Cameron et al.⁵ measured a cross section of $(1.4 \pm 0.2) \times 10^{-17}$ cm² molecule⁻¹ at 220 nm. Cameron et al.⁵ also measured the spectrum using diode array spectroscopy in the range 190–247 nm; the shape of the spectrum being in reasonable agreement with the spectrum measured by Maricq and Szenté.⁶ The spectrum by Cameron et al.⁵ is given by the equation:

$$\sigma = \sigma_{\max} \exp \left[-a \left[\ln \left(\frac{\lambda_{\max}}{\lambda} \right) \right]^2 \right]$$

where

$$\sigma_{\max} = 1.549 \times 10^{-17} \quad a = 129.19 \quad \lambda_{\max} = 213.985$$

The visible absorption spectrum of CH₃CO was measured by Rajakumar et al.⁸ in the wavelength range 490–660 nm using cavity ring-down spectroscopy. The spectrum has a broad continuous band with a broad peak at 535 nm. The spectrum obtained with the H₂O₂ photolysis source (in the presence of CH₃CHO) was used as a reference and fit with an empirical polynomial expression:

$$\sigma(\lambda) = A + B\lambda + C\lambda^2 + D\lambda^3 + E\lambda^4$$

yielding the parameters (σ in units of cm² molecule⁻¹, λ in nm)

$$\begin{aligned} A &= -6.6124 \times 10^{-17} & D &= 1.02141 \times 10^{-24} \\ B &= 4.1946 \times 10^{-19} & E &= -3.93411 \times 10^{-28} \\ C &= -9.865 \times 10^{-22} \end{aligned}$$

The recommended UV absorption cross sections in Table 4D-11-1 were calculated using the equation from Cameron et al.⁵ The recommended cross sections in the visible region in Table 4D-11-2 were calculated using the polynomial expression from Rajakumar et al.⁸

D12. CH₃C(O)O₂ (acetylperoxy radical)[Back to Index](#)

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of the acetylperoxy radical, CH₃C(O)O₂, is continuous with two absorption bands in the 185–300 nm region. The band centered at 245 nm is overlapped by a stronger band that peaks near 207 nm. Absorption cross sections have been measured at room temperature by Addison et al.,¹ Basco and Parmer,² Moortgat et al.,⁵ Maricq and Szenté,⁴ and Roehl et al.⁶ The absorption cross sections have been evaluated in reviews by Lightfoot et al.,³ Wallington et al.,⁸ and Tyndall et al.⁷ and significant discrepancies in the both the shapes of the spectra and the absolute magnitude of the cross section values have been noted. Tyndall et al.⁷ fit the absorption spectrum reasonably well to the sum of two Gaussian shaped absorption bands:

$$\sigma = \sigma_{\text{max1}} \exp^{-a_1 \left[\ln \left(\frac{\lambda_{\text{max1}}}{\lambda} \right) \right]^2} + \sigma_{\text{max2}} \exp^{-a_2 \left[\ln \left(\frac{\lambda_{\text{max2}}}{\lambda} \right) \right]^2}$$

The optimized fit parameters were determined by averaging the fit parameters from Maricq and Szenté⁴ and Roehl et al.,⁶ which were judged to be the most reliable. It should be noted that the data from Maricq and Szenté were adjusted for their overcorrection for the contribution of CH₃O₂. Absolute cross sections were based on relative measurements to the absorption cross sections of C₂H₅O₂ at 240 nm. The fitting parameters are:

$$\begin{array}{ll} \sigma_{\max 1} = 6.29 \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1} & \sigma_{\max 2} = 3.26 \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1} \\ \lambda_{\max 1} = 206.0 \text{ nm} & \lambda_{\max 2} = 246.1 \text{ nm} \\ a_1 = 168.0 & a_2 = 64.2. \end{array}$$

The recommended absorption cross sections in Table 4D-5 are taken from the review by Tyndall et al.⁷

Photolysis Quantum Yield and Product Studies: The loss of CH₃C(O)O₂ in the stratosphere and troposphere due to photolysis is expected to be negligible.

D13. CH₃CHO (acetaldehyde)

[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of acetaldehyde, CH₃CHO, has been measured at room temperature by McMillan⁴ (200–345 nm), Meyrahn et al.¹⁴ (221–345 nm), Schneider and Moortgat¹⁵ (197–362 nm), Libuda et al.^{8,9} (235–360 nm), Martinez et al.¹² (202–365 nm), Limão-Vieira et al.¹⁰ (240–350 nm), and Weaver et al.¹⁶ (290–355 nm). The spectrum at wavelengths >200 nm consists of an absorption band with a peak at 290 nm and diffuse vibrational structure (~12 maxima or shoulders) at wavelengths >260 nm. The agreement between the various cross section studies is very good, mostly 5% or better, except for the results from Meyrahn et al.,¹⁴ which are lower by ~10% in the structured region around the absorption maximum. The recommended cross sections in Table 4D-13-1 are based on the data of Libuda et al.^{8,9} (1 nm averages of 0.6 nm resolution data) and Martinez et al.¹² (4 nm averages of 0.5 nm resolution data at 202–278 nm and 1 nm averages at 280–360 nm), for which the agreement is within 5% between 255 and 325 nm.

Spectrum measurements in the VUV have been reported by Lake and Harrison⁷ (150–180 nm), Lucazeau and Sandorfy¹¹ (118–189 nm), Brint et al.² (120–180 nm), and Limão-Vieira et al.¹⁰ (113–200 nm).

Photolysis Quantum Yield and Product Studies: The photodissociation quantum yield of CH₃CHO and the product quantum yields are wavelength and pressure dependent. Quantum yield measurements have been reported by Calvert and Pitts⁴ and Weaver et al.¹⁶ at isolated wavelengths between 290 and 332 nm. Quantum yields of CO, CH₄ and CO₂ were determined in the photolysis of trace concentrations of CH₃CHO in air and N₂ in the spectral range 250–330 nm at 1 atmospheric pressure by Meyrahn et al.,¹⁴ which allowed the determination of (Φ₁ + Φ₂), Φ₂, and Φ₃. The product quantum yield pressure dependence was also investigated by Meyrahn¹³ at 270, 303.4 and 313 nm. Horowitz et al.⁶ and Horowitz and Calvert⁵ measured the quantum yields of CO, CH₄ and H₂ formation at 290, 300, 313, 320 and 332 nm in the presence of various pressures of O₂ and CO₂ from which Φ₁ and Φ₂ were derived. There is evidence from the studies of Meyrahn et al.^{13,14} and Horowitz et al.⁶ that some CO₂ is formed from secondary reactions of the CH₃CO radical that is produced in channel (3). The quantum yield for channel 3 was estimated to be 0.025 at 300 nm and to decrease to zero at

320 nm. Both Meyrahn et al.^{13,14} and Horowitz et al.^{5,6} observed a pressure dependence of the product yields, from which Stern-Volmer quenching coefficients were derived. These data were summarized by Calvert et al.³

The quantum yield recommendation given in Table 4D-13-2 for room temperature and atmospheric pressure are based on the evaluation by Atkinson and Lloyd¹ and the measurements by Horowitz and Calvert,⁵ Meyrahn et al.,¹⁴ and Meyrahn.¹³

D14. CH₃CHOO (acetaldehyde oxide)

[Back to Index](#)

(Recommendation: 19-5; Note: 19-5; Evaluated: 19-5)

Absorption Cross Sections: UV absorption cross sections of the Criegee intermediate CH₃CHOO (acetaldehyde oxide) have been reported at room temperature by Beames et al.¹ (280–372 nm), Smith et al.³ (280.2–440.6 nm), and Sheps et al.² (300–450 nm). The cross section values of Smith et al. and Beames et al. are in substantial disagreement, with the cross sections of Smith et al. lower by up to a factor of ~4.5. In addition, the spectral shape of these two studies are also significantly different. Smith et al. used SO₂ scavenging and self-reaction of CH₃CHOO to measure the shape of the absorption spectrum and assigned absolute cross sections at 308.4 and 351.8 nm based on molecular beam laser-depletion measurements. Beames et al. also used laser depletion in a molecular beam to determine absolute cross sections, but experimental factors, such as inhomogeneity of the laser beam and laser-molecular beam overlap, led to larger uncertainties (estimated by Beames et al. to be on the order of a factor of 2).

Sheps et al. presented UV absorption spectra for both conformers of acetaldehyde oxide, *syn*- and *anti*-CH₃CHOO, by separating them based on their decay times in the presence of H₂O. The UV spectrum of *syn*-CH₃CHOO is centered at 323 nm with FWHM of ~40 nm, and *anti*-CH₃CHOO is centered at ~360 nm with FWHM ~55 nm. The *syn*-CH₃CHOO conformer is more stable and thus more populated, reported to be 70% relative to 30% for the *anti*-CH₃CHOO.

Sheps et al. did not measure absolute cross sections, rather they scaled their measured spectrum of *syn*-CH₃CHOO to the cross section value of Smith et al. at 308.4 nm (a wavelength where absorption by the *syn*-conformer dominates). Sheps et al. found that their spectral shape was less intense on the low-energy side relative to the spectrum of Smith et al. However, summing the absorptions attributed to both *syn*- and *anti*-conformers in the Sheps et al. study led to good overall agreement with Smith et al., suggesting that the spectrum of Smith et al. contains unresolved contributions from both conformers. Sheps et al. estimated that the peak cross section for *anti*-CH₃CHOO is similar to the *syn*-conformer, but it should be noted that Sheps et al. considered their derivation of the cross sections for *anti*-CH₃CHOO to be a qualitative guide with large uncertainties. Theoretical UV spectra calculated by Sršeň et al.⁴ show the *anti*-conformer to have a peak cross section slightly greater than *syn*-CH₃CHOO. Relative to the experimental spectra of Sheps et al., the calculated spectra of Sršeň et al. are shifted slightly to shorter wavelengths for the *anti*-conformer but are in good agreement for the *syn*-conformer.

The recommended cross sections given in Table 4D-14 are from Smith et al. and represent 5 nm averages of their data (reported every ~0.6 nm) between 285–435 nm. Estimated uncertainty factors (2σ) are recommended to be 1.2 below 390 nm and increase linearly to 1.4 at 435 nm.

Photolysis Quantum Yield and Product Studies: No recommendation.

D15. C₂H₅O₂ (ethylperoxy radical)

[Back to Index](#)

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The absorption cross sections of the ethylperoxy radical, C₂H₅O₂, in the 200–310 nm region have been measured at room temperature by Adachi et al.,¹ Cattell et al.,⁴ Wallington et al.,¹⁴ Bauer et al.,³ Maricq and Wallington,⁹ Fenter et al.,⁶ Munk et al.,¹⁰ and Nielsen et al.¹¹ and as a function of temperature by Anastasi et al.,² Fenter et al.,⁶ and Fauvet et al.⁵ The absorption cross sections have been evaluated in reviews by Lightfoot et al.⁷ and Wallington et al.,¹⁵ who noted significant discrepancies in the both the shapes of the spectra and the absolute magnitude of the cross section values. The ultraviolet absorption spectra have recently been reevaluated by Tyndall et al.,¹³ who fit the absorption spectra to a semi-logarithmic Gaussian distribution function suggested by Lightfoot et al.⁷ and Maric et al.:⁸

$$\sigma = \sigma_{\text{max}} \exp^{-a \left[\ln \left(\frac{\lambda_{\text{max}}}{\lambda} \right) \right]^2}$$

The shape was determined by averaging the individual fitting parameters from Wallington et al.,¹⁵ Bauer et al.,³ Maricq and Wallington,⁹ and Fenter et al.,⁶ which were judged to be most reliable by Tyndall et al.¹³ Absolute cross sections were based on relative measurements of absorption cross sections of CH₃O₂ and C₂H₅O₂ at 240 nm taken under identical conditions (Wallington et al.,¹⁵ Maricq and Wallington,⁹ Fenter et al.,⁶ Roehl et al.¹²) and Nielsen et al.¹¹ combined with independent calibrations. The fitting parameters are $\sigma_{\text{max}} = 4.52 \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1}$, $a = 49.0$, $\lambda_{\text{max}} = 239.4 \text{ nm}$. Table 4D-5 lists the recommended cross sections, which are taken from the review by Tyndall et al.

Photolysis Quantum Yield and Product Studies: No recommendation. The loss of C₂H₅O₂ due to photolysis in the stratosphere and troposphere is expected to be negligible.

D16. CH₃CH₂OH (ethanol, ethyl alcohol)

[Back to Index](#)

(Recommendation: 19-5, Note: 25-1, Evaluated: 25-1)

Absorption Cross Sections: UV absorption cross sections of CH₃CH₂OH (ethanol) have been measured at room temperature by Ogawa and Cook⁵ (50.8–174.9 nm), Harrison et al.⁴ (168 nm, 181 nm), Tsubomura et al.⁹ (164.9–185.6 nm), Salahub and Sandorfy⁷ (120.5–208.3 nm), Han et al.³ (46–200 nm), Feng and Brion² (6.2–248.0 nm), Dillon et al.¹ (184.9 nm), and Orkin et al.⁶ (161.7–216.0 nm). Three studies have continuous wavelength coverage from 165–200 nm: Salahub and Sandorfy, Han et al., and Orkin et al., which are all in good agreement near the peak cross section at 182 nm, but generally diverge toward shorter and longer wavelengths. Three studies report single wavelength cross section measurements near the 182 nm peak: Feng and Brion (177.12 nm), Harrison et al. (181 nm), and Dillon et al. (184.9 nm), which all agree to within 10% with the three studies that have continuous coverage. The measurements of Tsubomura et al. and Ogawa and Cook disagree significantly with the other studies at wavelengths >165 nm.

The recommended cross sections given in Table 4D-16 for 165–216 nm were taken from Orkin et al. at 1 nm intervals (higher resolution data are available in Orkin et al.) after rounding to 3 significant figures. For the range 220–230 nm, the recommended values were obtained from a log-linear fit (206–216 nm) and extrapolation of the Orkin et al. data, $\log \sigma(\lambda) = 11.1187 - 0.15069 \lambda$. Estimated uncertainty factors (2σ) of $F(\lambda) = 1.1 + 6 \times 10^{-23}/\sigma(\lambda)$ are recommended for the 165–216 nm wavelength range.

VUV absorption spectra of CH₃CH₂OH in the Lyman- α (121.567 nm) wavelength region have been reported by Ogawa and Cook,⁵ Salahub and Sandorfy,⁷ Han et al.,³ Feng et al.,² and Souza Barbosa et al.⁸ The agreement among these studies at Lyman- α is reasonably good, although the Ogawa and Cook cross sections are systematically high. The recommended Lyman- α (121.567 nm) cross section is an average of the data of Salahub and Sandorfy and Han et al. with an estimated uncertainty factor (2σ) of 1.2.

Photolysis Quantum Yield and Product Studies: No recommendation.

Table 4D-16. Recommended Absorption Cross Sections of CH₃CH₂OH (ethanol) at 295 K

λ (nm)	$10^{20} \sigma$ (cm ²)	λ (nm)	$10^{20} \sigma$ (cm ²)	λ (nm)	$10^{20} \sigma$ (cm ²)

D17. HOCH₂CHO (glycolaldehyde, hydroxyacetaldehyde)

[Back to Index](#)

HOCH ₂ CHO + hν	→ CH ₂ OH + HCO	345 kJ mol ⁻¹	347 nm	(1)
	→ CH ₃ OH + CO	6 kJ mol ⁻¹	1910 nm	(2)
	→ OH + CH ₂ CHO	365 kJ mol ⁻¹	328 nm	(3)
	→ HOCH ₂ CO + H	381 kJ mol ⁻¹	314 nm	(4)

(Recommendation: 10-6, Note: 25-1, Evaluated: 25-1)

Absorption Cross Sections: The absorption cross sections of HOCH₂CHO (glycolaldehyde, hydroxyacetaldehyde) have been measured at room temperature by Bacher et al.¹ (205–335 nm), Magneron et al.³ (210–330 nm), Karunanandan et al.² (210–335 nm), and Zhu and Zhu⁴ (280–340 nm). The spectrum consists of a strong absorption below 220 nm and a weaker absorption band centered near 280 nm with evidence of weak diffuse vibrational progressions. The measurements performed by Magneron et al.³ were done at two different laboratories and are nearly identical, but reveal significant differences compared to the spectrum measured by Bacher et al.,¹ being about 20% at the maximum. The spectrum measured by Karunanandan et al.² is in excellent agreement with Magneron et al.³ at the maximum near 282 nm and at longer wavelengths. At shorter wavelengths, the cross sections are consistently larger than those measured by Magneron et al.;³ 15% at 250 nm, 40% at 230 nm and 85% at the minimum near 226 nm. At 184.9 nm, the cross section was measured by Karunanandan et al.² to be $(3.85 \pm 0.2) \times 10^{-18}$ cm² molecule⁻¹. The Zhu and Zhu⁴ measurements were performed using cavity ring-down spectroscopy. Their results are consistent with previous studies between 280 and 325 nm, but show a systematic increase at longer wavelengths relative to the other measurements. The average of the cross sections of Magneron et al.³ and Karunanandan et al.² are recommended and listed in Table 4D-17.

Photolysis Quantum Yields and Product Studies: The broad band photolysis (285 ± 25 nm) of glycolaldehyde in air performed by Bacher et al.¹ revealed an overall quantum yield $\Phi > 0.5$, relative to a quantum yield of $\Phi = 0.3$ for the removal of acetone. Product studies with FTIR detection suggests that channel (1) is the major photolysis channel (65–80%), while channel (2) accounts to 15–20%, and channel (3) contributes up to 15%. The formation of channel (4) was suggested to produce HOCH₂CO as a source for OH radicals, whose presence was indirectly invoked due the formation of glyoxal. Magneron et al.³ also photolysed glycolaldehyde (broadband lamps 275–380 nm) and measured products by FTIR (CO, CO₂, HCHO and CH₃OH). They observed direct evidence for OH production via channel (3) using an OH scavenger and OH tracer species. They performed additional photolysis experiments where glycolaldehyde was used as an OH source to measure rate constants for OH with a series of dienes. The contribution of channel (2) was estimated to be 10% and that of channels (1) + (2) to be 90%. No evidence was found for channel (4). Karunanandan et al.² measured a quantum yield of OH formation at 248 nm of $\Phi_3 = (7.0 \pm 1.5) \times 10^{-2}$. Zhu and Zhu used laser photolysis combined with cavity ring-down spectroscopy to measure HCO quantum yields of 0.61, 0.59, 0.61, 0.66, 0.61, 0.65, 0.47, 0.52, and 0.45 at 280, 285, 290, 295, 300, 305, 308, 310, and 315 nm, respectively. The estimated 1σ absolute error in the measurements were in the 35 to 50% range. They also report a OH quantum yield of 0.11 for 308 nm photolysis. On the basis of the combined product studies the following quantum yields are recommended: $\Phi_1 = 0.83$, $\Phi_2 = 0.10$ and $\Phi_3 = 0.07$ in the range 248–328 nm.

Table 4D-17. Recommended Absorption Cross Sections of HOCH₂CHO at 298 K

λ (nm)	$10^{20} \sigma$ (cm ²)	λ (nm)	$10^{20} \sigma$ (cm ²)	λ (nm)	$10^{20} \sigma$ (cm ²)	λ (nm)	$10^{20} \sigma$ (cm ²)

D18. HC(O)OCH₃ (methyl formate)

[Back to Index](#)

(1)

(Recommendation: 25-1, Note: 25-1, Evaluated: 25-1)

Absorption Cross Sections: The UV absorption spectrum of methyl formate, HC(O)OCH₃, has been measured at room temperature by Barnes and Simpson¹ (118–242 nm), McMillan³ (201–260 nm), Suto et al.⁷ (106–247 nm), Vésine and Mellouki⁸ (211–260 nm), Benayadal and Leila² (211–252 nm), Rocha et al.⁶ (200–238 nm), Nunes et al.⁵ (115–315 nm), and by Doner et al.⁴ (128–240 nm) at 323 K. The UV spectrum consists of a continuous absorption band with a maximum near 215 nm and weak diffuse structure. The Suto et al. and Doner et al. spectra are in poor agreement with the other studies and are not considered in the recommendation. For the other studies, the agreement is better than 10%. The recommended cross sections in Table 4D-18 are taken from Calvert³ for the region 202–210 nm (read from a figure) and Vésine and Mellouki⁸ for the region 211–260 nm. The Vésine and Mellouki⁸ data given here are obtained from their high resolution (0.04 nm) spectrum over 1 and 2 nm intervals in the ranges 211–230 and 230–260 nm, respectively.

VUV absorption cross sections in the Lyman- α (121.567 nm) wavelength region have been reported by Barnes and Simpson,¹ Suto et al.,⁷ and Nunes et al.⁵ These studies are in good agreement and a Lyman- α cross section of 2.38×10^{-17} cm² molecule⁻¹ is recommended.

Photolysis Quantum Yield and Product Studies: No recommendation.

D19. CHOCHO (glyoxal)

[Back to Index](#)

CHOCHO + hν → HCO + HCO	300 kJ mol ⁻¹	399 nm	(1)
→ H ₂ + 2 CO	-8 kJ mol ⁻¹	All	(2)
→ HCHO + CO	-7 kJ mol ⁻¹	All	(3)
→ H + CO + HCO	364 kJ mol ⁻¹	329 nm	(4)

(Recommendation: 10-6, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV/vis absorption spectrum of glyoxal, CHOCHO, has been measured in a number of studies. The spectrum has two absorption bands in the wavelength region >220 nm; a weak band with evidence of diffuse vibrational structure in the 220–350 nm region, and a stronger and highly structured band at wavelengths >360 nm with a maximum near 455 nm. The absorption cross sections, particularly in the visible absorption band, are resolution dependent and comparison of results from the various studies need to take this into consideration. The room temperature absorption spectrum of glyoxal has been reported by Plum et al.¹¹ (230–460 nm), Langford and Moore⁶ (308 nm), Zhu et al.¹⁵ (193, 248, 308, and 351 nm), Chen and Zhu³ (290–420 nm, in 10 nm intervals), Orlando and Tyndall⁹ (210–450 nm, 0.6 nm resolution), Horowitz et al.⁵ (210–480 nm, 0.25 nm resolution), Zhu and Johnston¹⁴ (436–442 nm), and Volkamer et al.¹³ (250–526 nm).

Orlando and Tyndall⁹ and Horowitz et al.⁵ reported absorption spectra obtained using diode array spectroscopy and their spectra are in good agreement, i.e., to better than 10% between 240 and 440 nm. The absorption cross sections from Chen and Zhu³ differ from these studies by 10 to 50% depending on the wavelength. However, the absorption cross sections reported by Zhu et al.¹⁵ at 248, 308, and 351 nm agree very well with the data of Horowitz et al.⁵ and Orlando and Tyndall.⁹ A strong absorption feature at wavelengths <200 nm indicated by the 193 nm measurement of Zhu et al.¹⁵ ($\sigma = 4.8 \times 10^{-19} \text{ cm}^2 \text{ molecule}^{-1}$) was also reported by Orlando and Tyndall.⁹ The cross section data from Plum et al.¹¹ are systematically less, by roughly 10 to 25%, than reported in the more recent studies with larger differences in the region of the absorption minimum near 350 nm and at the shorter wavelengths.

Volkamer et al.¹³ reported the highest available resolution absorption spectra of glyoxal to date which were obtained using Fourier transform spectroscopy at 1 cm^{-1} (250–526 nm) and 0.06 cm^{-1} (368–526 nm) resolution. The high-resolution spectrum has more pronounced differential vibrational fine structure in the visible absorption band leading to higher absorption cross sections than reported in the lower resolution studies. The absorption cross sections reported by Volkamer et al.¹³ are systematically 10% greater than reported by Horowitz et al.⁵ and Orlando and Tyndall⁹ (where comparison is possible). The differences in the absorption cross sections are most apparent in the short wavelength band. The UV spectrum reported by Volkamer et al.¹³ is consistent with IR spectral parameters which were obtained by simultaneous recording of UV and IR spectra using the same glyoxal sample fillings of the absorption cell. Zhu and Johnston¹⁴ report an absorption cross section at the absorption maximum near 440.7 nm (440.1 nm in the Volkamer et al. spectrum) of $4.6 \times 10^{-19} \text{ cm}^2 \text{ molecule}^{-1}$ that was obtained at high resolution using cavity ring-down spectroscopy. Their cross section value is in poor agreement with the high resolution data of Volkamer et al.¹³ which is a factor of two greater. The recommended room temperature absorption cross sections in Table 4D-19-1 are averages over 1 nm intervals of the high resolution spectrum from Volkamer et al.¹³ and are appropriate for use in atmospheric photolysis rate calculations. Studies requiring higher resolution data should consult the original literature.

Photolysis Quantum Yield and Product Studies: The photodissociation of CHOCHO as well as the photolysis product channel yields are wavelength and pressure dependent. Calvert and Pitts² have summarized the CHOCHO quantum yield data prior to 1966. On the basis of the work by Calvert and Layne¹ and Parmenter¹⁰ it was established that the HCHO + CO photolysis channel (3) was dominant with yields between 0.84 and 0.6 over the wavelength range 254 to 435 nm. There was little experimental evidence for the HCO + HCO radical channel (1) occurring and it was incorrectly concluded to be negligible. Plum et al.¹¹ has since reported the effective quantum yield for CHOCHO photolysis at wavelengths >290 nm to be 0.029, based on measured photolysis rates in an environmental chamber relative to NO₂ where $J_{\text{CHOCHO}}/J_{\text{NO}_2}$ was found to be 0.008 ± 0.005 . An effective atmospheric photolysis rate was measured using solar radiation in the EUPHORE outdoor chamber to be $J_{\text{obs}} = 1.04 \pm 0.10 \times 10^{-4} \text{ s}^{-1}$, corresponding to an effective quantum yield for glyoxal loss of 0.035 ± 0.007 ^{7,8} in reasonable agreement with the value reported by Plum et al.¹¹

Langford and Moore⁶ measured HCO produced in the photolysis of glyoxal in 1000 Torr N₂ at 305 nm by direct HCO resonance absorption and deduced a total HCO yield of 0.8 ± 0.4 at 305 nm. Using cavity ring-down spectroscopy, Zhu et al.¹⁵ reported HCO quantum yields of 1.5 ($\Phi_1 \approx 0.75$) for photolysis at 351 nm, 0.69 at 308 nm, 0.52 at 248 nm and 0.42 at 193 nm. In a later study Chen and Zhu³ reported zero pressure HCO yields, $\Phi_0(\lambda)$, at 10 nm intervals, that increase from 0.50 ± 0.01 at 290 nm to a maximum of 2.01 ± 0.08 at 390 nm and that decrease to 0.74 ± 0.08 at 400 nm, 0.56 ± 0.04 at 410 nm, and 0.48 ± 0.03 at 420 nm. HCO quantum yields were found to be independent of the N₂ buffer gas pressure (10–400 Torr) for photolysis in the 290–370 nm region. In the wavelength region 380–420 nm the HCO quantum yield decreased with increasing pressure. They reported HCO quantum yields at 760 Torr N₂ to be 0.49 at 380 nm, 0.54 nm at 390 nm, 0.32 at 400 nm, 0.22 at 410 nm and 0.14 at 420 nm. Feierabend et al.⁴ measured quantum yields for the production of HCO at 85 discrete wavelengths in the wavelength range 290–420 nm at pressures between 50 and 550 Torr (N₂) at 298 K using pulsed laser photolysis combined with cavity ring-down spectroscopy detection of HCO. $\Phi_0(\lambda)$ varied smoothly with wavelength with a maximum value of ~ 1.8 in the range 300–385 nm with values decreasing to near 0 at 420 nm and 0.4 at 290 nm. The high precision of the measurements enabled the pressure dependence of the HCO quantum yield to be determined at each wavelength using the Stern-Volmer relationship:

$$\frac{1}{\Phi(\lambda, P)} = \frac{1}{\Phi_0(\lambda)} + \frac{k_q}{k_d}(\lambda)[\text{N}_2]$$

where k_q is the collisional quenching rate coefficient and k_d is the rate coefficient for the dissociation of glyoxal. The wavelength dependence of the rate coefficient ratio was fit to the expression

$$k_q/k_d(\lambda) = 2.3 \times 10^{-20} + 1.5 \times 10^{-19} \exp(-0.4 \Delta E) \quad (\text{cm}^3 \text{ molecule}^{-1})$$

where $\Delta E = ((28571/\lambda) - 72.5)$ (kcal mol⁻¹), λ is the photolysis wavelength (nm), and 72.5 kcal mol⁻¹ is the threshold for glyoxal photodissociation (there is a small barrier to dissociation on the triplet surface). The $\Phi_0(\lambda)$ values from the Feierabend et al.⁴ work are in good agreement with the values reported by Chen and Zhu.³

Tadić et al.¹² photolysed glyoxal with broadband fluorescent lamps, which selectively overlapped with the two absorption bands, and measured the CO, HCHO and HCOOH end products. Using 275–380 nm irradiation, the quantum yield for glyoxal loss was found to be $\Phi_T = 0.97 \pm 0.05$ and independent of pressure. The absolute quantum yields obtained for 390–470 nm radiation, covering the visible absorption band, were found to be pressure dependent with values ranging from $\Phi_T = 0.12$ at 100 Torr to $\Phi_T = 0.04$ at 700 Torr and was described by the Stern-Volmer expression:

$$\frac{1}{\Phi_T} = 6.80 + [251.8 \times 10^{-4} P(\text{Torr})]$$

The direct HCO quantum yield measurements of Feierabend et al.⁴ and Chen and Zhu³ combined with the end product yield results of Tadić et al.¹² indicate that dissociation into 2 HCO radicals is the most important pathway under atmospheric conditions. On the basis of their HCO quantum yield data, Feierabend et al. reported a set of revised wavelength dependent quantum yields for channels (1), (2) and (3) from those of Tadić et al.,¹² which were recommended in NASA/JPL 06-2. The revised quantum yields are recommended and given in Table 4D-19-2. Although glyoxal has a very low effective quantum yield, photolysis is an important removal path in the atmosphere.

	→ CH ₃ COO + H	462 kJ mol ⁻¹	259 nm	(4)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of acetic acid, CH₃C(O)OH, and the acetic acid dimer, (CH₃C(O)OH)₂, have been measured for a range of sample pressures at 300 K by McMillan¹ (200–241 nm; 12.9, 11.0, 8.3, and 3.6 Torr), at 283, 303 and 338 K by Hintze et al.² (195–220 nm), and at 270, 298, 325, and 345 K by Orlando and Tyndall⁴ (210–245 nm; 0.12–3.6 Torr). Singleton et al.⁵ reported cross sections at 222 nm in connection with quantum yield measurements at 298 and 356.2 K. The monomer spectrum reported by Orlando and Tyndall⁴ and Hintze et al.² has a broad maximum near 207 nm and a monotonic decrease in intensity with increasing wavelength. The absorption maximum for the dimer appears at shorter wavelength, below 205 nm, and is twice as intense as that of the monomer. The decrease in cross sections with increasing wavelength is more rapid for the dimer than for the monomer resulting in the monomer cross section being greater at 240 nm by a factor 6. Hinze et al.² determined the absorption cross section at the maximum for the monomer at 206.1 nm and 297 K to be $(1.27 \pm 0.10) \times 10^{-19}$ cm² molecule⁻¹ and for the dimer and at 208.1 nm to be $(2.44 \pm 0.08) \times 10^{-19}$ cm² molecule⁻¹. The absorption spectra reported by Calvert and Pitts¹ were derived assuming monomers only in spite of undefined amounts of monomer and dimer. The absorption spectrum for the greatest pressure is close to the dimer spectrum reported by Orlando and Tyndall⁴, suggesting that the sample was primarily dimer at the higher pressures. The recommended absorption cross sections in Table 4D-20 are taken from Orlando and Tyndall⁴ (measured at 0.6 nm resolution).

Photolysis Quantum Yield and Product Studies: Early photolysis studies reported yields of the end products CO, CO₂, CH₄, and C₂H₆ (Calvert and Pitts¹) and proposed molecular elimination (channel 1) and radical formation (channels 2–4) originating from the monomer. Hunnicutt et al.³ photolysed acetic acid at 218 nm and used photofragment laser fluorescence to determine channel (2) to be the dominant photochemical path. Singleton et al.⁵ determined the OH quantum yield at 222 nm to be 0.546 ± 0.097 at 298 K and 0.692 ± 0.024 at 356.2 K for the monomer and 0.038 ± 0.026 at 298 K for the dimer (a dimer quantum yield of zero was assumed at elevated temperatures).

D21. CH₃C(O)OOH (peracetic acid)

[Back to Index](#)

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of peracetic acid, CH₃C(O)OOH, was measured at 248 and 298 K by Orlando and Tyndall¹ (205–340 nm). The absorption cross sections decrease in a monotonic near-exponential fashion with increasing wavelength. The spectrum recorded at 248 K shows a faster fall-off with increasing wavelength than that recorded at room temperature. The recommended absorption cross sections in Table 4D-21 are taken from Orlando and Tyndall (the only study available) (measured at 0.6 nm resolution).

Photolysis Quantum Yield and Product Studies: No recommendation.

→ CH ₃ + CH ₂ CHO	343 kJ mol ⁻¹	349 nm	(4)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of propionaldehyde (C₂H₅CHO, propanal) has been measured at room temperature by Lucazeau and Sandorfy⁵ (118–190 nm), McMillan² (220–342 nm), and Martinez et al.⁶ (262–365 nm). Absorption cross sections have also been reported for isolated wavelengths by Blacet and Crane¹ (187–313 nm), Heicklen et al.⁴ (293–325 nm), and Chen and Zhu³ (280–330 nm). The spectrum at wavelengths >200 nm consists of an absorption band with structured features (~9 maxima or shoulders) at wavelengths >260 nm and maximum absorption at 285 and 293 nm. The agreement between the results from Martinez et al.⁶ and McMillan² is excellent, i.e., ≤5% differences, between 238 and 322 nm. At shorter (longer) wavelengths the differences increase to ~30% (~50%). The data points reported by Heicklen et al.⁴ fit well to these studies although the value reported at 293 nm is 20% smaller. The cross sections reported at 5 nm intervals by Chen and Zhu³ agree to within 10% with those reported by Martinez et al.,⁶ except the data at 285 and 330 nm which are 20% and 30% larger. The recommended absorption cross sections listed in Table 4D-22 are taken from Martinez et al.⁶ and are 4 nm averages of the 0.5 nm resolution data in the region 202–278 nm and 1 nm averages in the region 280–360 nm.

Photolysis Quantum Yield and Product Studies: Quantum yield measurements have been performed by Heicklen et al.⁴ and Chen and Zhu.³ Heicklen et al.⁴ measured the quantum yield of HO₂ and C₂H₅O₂ radicals (in air bath gas) using laser photolysis at 294, 302, 312, and 325 nm combined with UV absorption to determine Φ₁. Quantum yields of CO and C₂H₆ were obtained in steady-state photolysis (at 254, 312, and 334 nm) experiments in O₂ where Φ₁ = Φ(CO) - Φ(C₂H₆) and Φ₂ = Φ(C₂H₆). A Stern-Volmer pressure dependence of the quantum yields was observed at all wavelengths, i.e., lower quantum yields at higher pressures. At atmospheric pressure, values of Φ₁ = 0.22, 0.89, 0.85, 0.50, 0.26, and 0.15 were derived at 254, 294, 302, 313, 325, and 334 nm, respectively. Heicklen et al.⁴ reported Φ₂ = 0.33 for 254 nm photolysis and Φ₂ = 0 at longer wavelengths. The contribution of other primary processes (Φ₃ and Φ₄) was found to increase at wavelengths <265 nm from earlier studies as cited in Calvert and Pitts.²

Chen and Zhu³ measured the quantum yield of HCO radicals (Φ_1) over the wavelength range 280–330 nm using time-resolved cavity ring-down spectroscopy with detection of HCO at 613.8 nm. The reported HCO yields are 0.85 ± 0.06 at 280 nm, 1.01 ± 0.07 at 285 nm, 0.95 ± 0.06 at 290 nm, 0.98 ± 0.06 at 295 nm, 0.92 ± 0.06 at 300 nm, 0.95 ± 0.08 at 305 nm, 0.98 ± 0.11 at 310 nm, 0.91 ± 0.05 at 315 nm, 1.08 ± 0.07 at 320 nm, 1.07 ± 0.14 at 325 nm, and 0.84 ± 0.08 at 330 nm. These values are quoted for zero-pressure but no pressure dependence to the HCO quantum yield at any wavelength was observed for pressures over the range 10–400 Torr N₂.

The quantum yield studies by Heicklen et al.⁴ and Chen and Zhu³ are only in agreement in the narrow wavelength range 290–305 nm. At $\lambda > 305$ nm, the data of Chen and Zhu do not show the decrease of Φ_1 reported by Heicklen et al.⁴ Because of the discrepancies between these data sets no quantum yield recommendation is given.

D23. C₂H₅CHOO (propionaldehyde oxide)[Back to Index](#)

(Recommendation: 19-5; Note: 19-5; Evaluated: 19-5)

Absorption Cross Sections: UV absorption cross sections of the Criegee intermediate C₂H₅CHOO (propionaldehyde oxide) have been reported at 298 K by Liu et al.¹ (288–368 nm). The Liu et al. measurements are the only UV absorption spectrum data currently available. Experimental factors in the Liu et al. study, such as inhomogeneity of the UV laser beam, led to large uncertainties in the absolute cross sections (estimated ~100% uncertainty in the original paper). Given the large cross sections reported from this research group for other Criegee intermediates using the UV photodissociation action spectrum technique, it is possible that the reported cross sections for C₂H₅CHOO are also over estimated. No recommendation for the absorption cross sections of C₂H₅CHOO is made at this time.

Photolysis Quantum Yield and Product Studies: No recommendation.

D24. (CH₃)₂COO (acetone oxide)[Back to Index](#)

(Recommendation: 19-5; Note: 19-5; Evaluated: 19-5)

Absorption Cross Sections: UV absorption cross sections of the Criegee intermediate (CH₃)₂COO (acetone oxide) have been reported at room temperature by Liu et al.⁴ (288–368 nm), Huang et al.³ (278.5–390.3 nm), Chang et al.¹ (308.4 nm, 351.8 nm), and Chhantyal-Pun et al.² (355 nm). The Huang et al. and Chang et al. studies are from the same research group: Huang et al. measured the spectrum wavelength dependence of (CH₃)₂COO, and Chang et al. scaled that spectrum to their absolute absorption cross section measured at 308.4 nm. The cross section values of Huang et al. / Chang et al. are in substantial disagreement with the cross sections of Liu et al., as the Liu et al. values are greater by more than a factor of 2 at the spectrum peak, 330 nm. Experimental factors in the Liu et al. study, such as inhomogeneity of the UV photolysis laser beam, led to significant uncertainties in their absolute cross sections.

The cross section value of Chhantyal-Pun et al. at 355 nm ($1.45 \pm 0.24 \times 10^{-17} \text{ cm}^2$) is significantly greater than the values from Huang et al. at 355 nm and Chang et al. at 351.8 nm; the uncertainties do not overlap. The reported value of Chhantyal-Pun et al. was not a direct measurement, as it was derived from the fractional loss of (CH₃)₂Cl₂ following photodissociation. The method used by Chang et al. of laser depletion in a molecular beam was previously used by the same research group to measure cross sections for other Criegee intermediates, CH₂OO and CH₃CHOO.

The recommended cross sections given in Table 4D-24 are from Huang et al., scaled to the cross sections of Chang et al. The recommended values represent 5 nm averages of the Huang et al. data (reported every ~0.6 nm) between 290–390 nm. An estimated uncertainty factor (2σ) of 1.5 is recommended, which is substantially larger than the uncertainty reported by Chang et al. but allows for overlapping error limits with the value of Chhantyal-Pun et al. at 355 nm.

Photolysis Quantum Yield and Product Studies: No recommendation.

D25. (CH₃)₂CHOH (isopropanol, 2-propanol, isopropyl alcohol)

[Back to Index](#)

(1)

(Recommendation: 19-5; Note: 19-5; Evaluated: 19-5)

Absorption Cross Sections: UV absorption cross sections of (CH₃)₂CHOH (isopropanol) have been measured at room temperature by Harrison et al.¹ (168 nm, 181 nm), Salahub and Sandorfy³ (120.5–208.3 nm), and Orkin et al.² (163–205 nm). At the local absorption maximum of 181 nm, the reported cross section of Harrison et al. is 7% greater than that reported by Orkin et al., while near the local absorption minimum of 168 nm, the value of Harrison et al. is 13% less. The cross sections of Salahub and Sandorfy agree to within 3%, or better, with Orkin et al. from 173 nm to the 181 nm peak, but the discrepancy increases at shorter and longer wavelengths. The recommended cross sections given in Table 4D-25 for the 163–205 nm wavelength range were taken from Orkin et al. at 1 nm intervals (higher resolution data are available in Orkin et al.). For the range 210–220 nm, the recommended values were obtained from a log-linear fit and extrapolation of the Orkin et al. data, $\log \sigma(\lambda) = 12.2226 - 0.15525 \lambda$. An estimated uncertainty factor of 1.13 (2σ) is recommended for the 163–205 nm wavelength range.

The recommended Lyman-α (121.567 nm) cross section was interpolated from the data of Salahub and Sandorfy³ with an estimated uncertainty factor (2σ) of 1.3.

Photolysis Quantum Yield and Product Studies: No recommendation.

D26. CH₃C(O)CH₃ (acetone)

[Back to Index](#)

(Recommendation: 06-2, Note: 10-6; Evaluated: 10-6)

Absorption Cross Sections: The absorption spectrum of acetone, CH₃C(O)CH₃, has been measured at room temperature by Lake and Harrison¹⁸ (159–203 nm), Calvert⁸ (200–300 nm), Meyrahn et al.^{20,21} (220–368 nm), Schneider and Moortgat (196–366 nm) (see Röth et al.²⁴), Hynes et al.¹⁴ (253.7 nm and 260–360 nm), Martinez et al.¹⁹ (202–335 nm), Gierczak et al.¹² (215–349 nm), Wollenhaupt et al.²⁹ (220–346 nm), and Yujing and Mellouki³⁰ (240–350 nm). Absorption cross sections have also been determined at isolated wavelengths by Braun et al.⁶ (193 nm, also for CD₃C(O)CD₃), Seki and Okabe²⁵ (193 nm), Krasnoperov and Mehta¹⁷ (216.51 nm), and Gierczak et al.¹³ (184.9 nm, also for CD₃C(O)CD₃).

The spectrum below 200 nm is highly structured in the wavelength regions 160–170 nm and 180–195 nm. A broad absorption band was observed between 210 and 340 nm for which higher resolution measurements give evidence for band maxima at ~273 and ~278 nm. The reported absorption cross sections are in excellent agreement with the range of deviations being ≤8% in the 240–320 nm region. The absorption cross section at the spectrum maximum range between 5.2×10^{-20} and 4.8×10^{-20} cm² molecule⁻¹. In the tails of the absorption band, the various data sets become more divergent with decreasing wavelength with differences of up to ~50% at 220 nm and with increasing wavelength up to more than 100% at 340 nm. The data measured by Meyrahn et al.^{20,21} are systematically higher at wavelengths >320 nm than the other studies. The absorption cross sections from Martinez et al.,¹⁹ Gierczak et al.,¹² Wollenhaupt et al.,²⁹ and Yujing and Mellouki³⁰ agree to within 2.5% in the region of the absorption maximum and to within 50% in the short and long wavelength tails of the band.

The absorption spectrum temperature dependence has been studied by Hynes et al.¹⁴ (300–340 nm) over the range 261–362 K, Gierczak et al.¹² (215–349 nm) over the range 235–298 K, and Gierczak et al.¹³ (184.9 nm, also for CD₃C(O)CD₃) over the range 222–296 K. The absorption spectrum has modest temperature dependence at wavelengths >270 nm with the cross sections decreasing with decreasing temperature. At shorter wavelengths the spectrum is essentially independent of temperature, the cross section changes by <5% between 298 and 235 K. Gierczak et al.¹² parameterized the temperature dependent cross sections using the expression:

$$\sigma(\lambda, T) = \sigma(\lambda, 298 \text{ K})[1 + c_1(\lambda)T + c_2(\lambda)T^2]$$

that was later superseded by Burkholder⁷ using the expression:

$$\sigma(\lambda, T) = \sigma(\lambda, 298 \text{ K})[1 + A(\lambda)T + B_2(\lambda)T^2 + C(\lambda)T^3]$$

The recommended absorption cross sections at 298 K in Table 4D-26-1 are taken from Gierczak et al.¹² and the temperature coefficients A, B, and C derived by Burkholder.⁷

The absorption cross section of CH₃C(O)CH₃ at 184.9 nm was observed to decrease very slightly with decreasing temperature between 296 and 222 K leading to an average value of $(2.98 \pm 0.10) \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1}$, whereas that of CD₃C(O)CD₃ increased noticeably from $3.91 \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1}$ (average of six results) at 295 K to $4.61 \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1}$ at 232 K, as reported by Gierczak et al.¹³

Photolysis Quantum Yield and Product Studies: The UV photodissociation of acetone is wavelength, pressure, and temperature dependent. Since NASA/JPL 06-2 there has been a number of acetone photodissociation laboratory studies published [Khamaganov et al.¹⁵ (248 and 266 nm), Khamaganov et al.¹⁶ (248 nm and 266 nm), Nádasdia et al.²² (248 nm and 308 nm), Rajakumar et al.²³ (248 nm), Somnitz et al.^{26,27} (248 nm)]. The focus of these studies has been on the determination of the pressure and temperature dependence of the acetone loss and product (CH₃, CH₃CO, CO, and CO₂) photolysis quantum yields as described further below.

Gardner et al.¹¹ measured acetone loss (Φ_{AC}) and formation of the products CO₂, CO, CH₃OH and H₂CO following the photolysis of dilute acetone-air mixtures at four wavelengths in the range 279–313 nm as a function of pressure (25–745 Torr) and temperature (271–301 K). At pressures >300 Torr, they observed a near constant quantum yield, $\Phi_{AC} \approx \Phi_{CO_2} = \Phi_1 = 0.077$, for photolysis wavelengths in the range 279–313 nm with a slight increase at lower pressures. Meyrahn et al.^{20,21} measured the quantum yields of CO and CO₂ in the photolysis of dilute mixtures of acetone in air at nine wavelengths over the range 250–330 nm. At 1 atm, Φ_{CO_2} decreased from 1.59 at 250 nm to 0.11 at 310 nm and increased to 0.27 at 330 nm. Φ_{CO} decreased from 0.45 at 250 nm to 0.02 at 310 nm and increased to 0.09 at 330 nm. A CO₂ quantum yield larger than unity was explained to result from secondary reactions. Meyrahn et al.^{20,21} measured the quantum yield of peroxyacetyl nitrate, Φ_{PAN} , (which is assumed to be a direct measure of Φ_1) in the photolysis of acetone /air/NO₂ mixtures to decrease from ~0.78 in the region 250–260 nm to 0.03 at 330 nm. Meyrahn et al.^{20,21} observed Φ_{CO_2} to increase at lower pressures (Stern-Volmer mechanism) at 330 nm. Emrich and Warneck^{9,10} also determined Φ_{PAN} following the photolysis of acetone /air/NO₂ mixtures at six wavelengths between 280 and 330 nm at total pressures in the range 10–760 Torr. At 760 Torr, Φ_{PAN} decreased from a value of 1.00 at 280 nm to 0.06 at 320 nm and increased to 0.13 at 330 nm. A Stern-Volmer type pressure dependence was observed at all wavelengths. The results were explained in terms of the rate of photodissociation from the excited singlet ¹[AC]* state of acetone and the competing intersystem crossing to the triplet ³[AC]*, both relative to that of collisional quenching, as a function of energy above the dissociation threshold. It was proposed that:

Gierczak et al.¹² determined Φ_{AC} and Φ_{CO_2} in the laser photolysis of acetone at nine wavelengths in the range 248–337 nm as a function of pressure (25–760 Torr, syn. air) and temperature (195–298 K). For photolysis wavelengths >270 nm, Φ followed a Stern-Volmer type pressure dependence and the zero-pressure quantum yield was found to increase with decreasing wavelength to a value of unity near 290 nm. Gierczak et al.¹² observed a temperature dependence for the 308 nm quantum yield except for the lowest temperature included in their study, 195 K, and choose to report a temperature independent quantum yield. The studies of Blitz et al.^{4,5} and Nádasdia et al.²² have since reported temperature dependent quantum yields at 308 nm. The results from these studies are in good agreement. The Gierczak et al.¹² results are also in reasonable agreement. The Gierczak et al.¹² results at 298 K are nearly identical to those of Emrich and Warneck.⁹ Gierczak et al.¹² and Warneck²⁸ have reported parameterizations for the quantum yields for the photodissociation of acetone dependence on wavelength and pressure.

Aloisio and Francisco¹ measured the quantum yield of acetone photodissociation at 248 and 308 nm in the presence and absence of water vapor. The apparent acetone quantum yield decreased from unity to 0.73 ± 0.07 for 248 nm photolysis and from 0.28 ± 0.07 to 0.06 ± 0.04 for 308 nm photolysis with the addition of 9 Torr of H₂O. Nádasdia et al.²² performed a similar quantum yield study (with and without H₂O) at 298 K and a total pressure of 133 mbar. They studied the effect for the same photolysis wavelengths and report quantum yields for the loss of acetone to be independent of H₂O vapor to within their measurement accuracy; 0.945 ± 0.222 (without H₂O) and 1.021 ± 0.124 (with 12 mbar H₂O) at 248 nm and two sets of measurements at 308 nm using different acetone and H₂O concentrations, 0.342 ± 0.028 (without H₂O) and 0.319 ± 0.018 (with 12 mbar H₂O) and 0.308 ± 0.024 (without) and 0.320 ± 0.024 (with 4 mbar H₂O). There is no explanation for the apparent discrepancy between these studies.

Blitz et al.^{4,5} reported the pressure and temperature (218–295 K) dependent quantum yields of acetone for photolysis wavelengths between 279 and 327.5 nm. Blitz et al.^{4,5} used a spectroscopic technique to indirectly detect the formation of the CH₃CO radical that is based on the detection of the OH radical formed in the reaction:

The time-resolved studies of Blitz et al.^{4,5} are more direct and sensitive than earlier studies. They observed “classical” Stern-Volmer behavior at $\lambda < 302$ nm, but at $\lambda > 302$ nm an extended form of the Stern-Volmer expression was necessary to fit their data for pressures below 15 Torr; reflecting the dissociation and quenching from both ¹[AC]* and ³[AC]* excited states as described in Blitz et al.³ On the basis of the low pressure quantum yield results at wavelengths > 300 nm, Blitz et al.^{4,5} determined that $\Phi_{\text{CH}_3\text{CO}} = 0.65$ and $\Phi_{\text{CO}} = 0.35$ at 248 nm from measurements made relative to this reference photolysis wavelength. Their analysis assumes that the acetone quantum yield in the low-pressure limit is unity in the long wavelength photolysis, the acetone quantum yield at 248 nm is unity, and that the CH₃CO quantum yield at 248 nm is independent of pressure. It has been established that the acetone quantum yield at 248 nm is unity and independent of temperature and pressure [Gierczak et al.,¹² Khamaganov et al.,¹⁶ Aloisio and Francisco,¹ Nádasdia et al.,²² and Somnitz et al.²⁷]. Khamaganov et al.¹⁶ also report that the acetone quantum yield is only weakly pressure dependent (60–760 Torr) at 266 nm. There is strong evidence now that the CH₃CO, CH₃, and CO quantum yields at 248 nm are, however, pressure dependent. For photolysis at 248 nm there is sufficient energy for the nascent energetically excited CH₃CO radical to dissociate via a non-concerted step:

or be collisionally quenched:

Khamaganov et al.¹⁵ (5–1500 Torr), Somnitz et al.^{26,27} (20–900 mbar), and Rajakumar et al.²³ (60–670 Torr) reported pressure dependent quantum yields for CH₃, CO and CO₂, and CH₃CO, respectively, over the range of pressures indicated. The results from these studies are in reasonable agreement and report low pressure quantum yields of $\Phi(\text{CH}_3) = 1.42 \pm 0.15$ (Khamaganov et al.¹⁵), $\Phi(\text{CO}) = 0.51$ (Sommnitz et al.²⁷), and $\Phi(\text{CH}_3\text{CO}) = 0.535 \pm 0.09$ (Rajakumar et al.²³). Somnitz et al.^{26,27} have modeled the dissociation process using RRKM theory with a time-dependent master equation approach. The impact of a pressure dependence for the CH₃CO quantum yield at 248 nm on the interpretation of the Blitz et al. quantum yield data at longer wavelengths is at present unclear.

At $\lambda < 310$ nm and 1 atm, there was very good agreement with the data of Gierczak et al.¹² and Emrich and Warneck⁹; however at $\lambda > 310$ nm, the measured quantum yields were significantly smaller. The temperature dependence of Φ_{TOTAL} is quite striking at the longer wavelengths: the ratio of the quantum yields at 295 and 218 K reported by Blitz et al.^{4,5} are $\Phi_{\text{TOTAL}}(295 \text{ K}) / \Phi_{\text{TOTAL}}(218 \text{ K}) \approx 4$ and ≈ 20 at 310 nm and 322.5 nm, respectively.

A major difference in the study of Blitz et al.,^{4,5} from several of the earlier studies is that the OH radicals are detected before undergoing secondary reactions, so that the OH yields represent the CH₃CO radicals produced. The quantum yields reported from the Gierczak et al.¹² and Emrich and Warneck⁹ studies were based upon the removal of CH₃C(O)CH₃, which may be affected by the additional loss of acetone due to the OH + acetone reaction where OH radicals are produced in the reaction of CH₃CO with O₂. However, the OH yield in the CH₃CO + O₂ reaction is a strong function of pressure and measurements made at pressures > 50 Torr are expected to have negligible errors.

The quantum yield data of Blitz et al.^{4,5} are recommended. The optimized parameterization of the quantum yields for the wavelength range 279–327.5 nm, temperature range 218–295 K and pressure range 0–1000 mbar is as follows:

$$\Phi_{\text{TOTAL}}(\lambda, [\text{M}], T) = \Phi_{\text{CH}_3\text{CO}}(\lambda, [\text{M}], T) + \Phi_{\text{CO}}(\lambda, T); \quad \text{all } \lambda$$

For $\lambda = 279\text{--}327.5$ nm

$$\Phi_{\text{CO}}(\lambda, T) = 1 / (1 + A_0)$$

where

$$A_0 = [a_0 / (1 - a_0)] \exp[b_0 (\lambda - 248)]$$

$$a_0 = (0.350 \pm 0.003) (T/295)^{(-1.28 \pm 0.03)}$$

$$b_0 = (0.068 \pm 0.002) (T/295)^{(-2.65 \pm 0.20)}$$

For $\lambda = 279\text{--}302$ nm

$$\Phi_{\text{CH}_3\text{CO}}(\lambda, [\text{M}], T) = (1 - \Phi_{\text{CO}}(\lambda, T)) / (1 + A_1[\text{M}])$$

where

$$A_1 = a_1 \exp[-b_1 ((10^7/\lambda) - 33113)]$$

$$a_1 = (1.600 \pm 0.032) \times 10^{-19} (T/295)^{(-2.38 \pm 0.08)}$$

$$b_1 = (0.55 \pm 0.02) \times 10^{-3} (T/295)^{(-3.19 \pm 0.13)}$$

For $\lambda = 302\text{--}327.5$ nm

$$\Phi_{\text{CH}_3\text{CO}}(\lambda, [\text{M}], T) = ((1 + A_4[\text{M}] + A_3) / [(1 + A_2[\text{M}] + A_3) (1 + A_4 [\text{M}])]) (1 - \Phi_{\text{CO}}(\lambda, T))$$

where

$$A_2 = a_2 \exp[-b_2 ((10^7/\lambda) - 30488)]$$

$$a_2 = (1.62 \pm 0.06) \times 10^{-17} (T/295)^{(-10.03 \pm 0.20)}$$

$$b_2 = (1.79 \pm 0.02) \times 10^{-3} (T/295)^{(-1.364 \pm 0.036)}$$

$$A_3 = a_3 \exp[-b_3 ((10^7/\lambda) - c_3)^2]$$

$$a_3 = (26.29 \pm 0.88) (T/295)^{(-6.59 \pm 0.23)}$$

$$b_3 = (5.72 \pm 0.20) \times 10^{-7} (T/295)^{(-2.93 \pm 0.09)}$$

$$c_3 = (30006 \pm 41) (T/295)^{(-0.064 \pm 0.004)}$$

$$A_4 = a_4 \exp[-b_4 ((10^7/\lambda) - 30488)]$$

$$a_4 = (1.67 \pm 0.14) \times 10^{-15} (T/295)^{(-7.25 \pm 0.54)}$$

$$b_4 = (2.08 \pm 0.02) \times 10^{-3} (T/295)^{(-1.16 \pm 0.15)}$$

where [M] is in molecule cm^{-3} , λ in nm and T in K. The equations given above have been used to calculate the quantum yields recommended in Table 4D-26-2.

It is well established that acetone photolysis at wavelengths >300 nm has a strong dependence on pressure and temperature but there remains some uncertainty in the absolute quantum yield values in this wavelength region. The effect of the temperature dependent quantum yields of acetone on the chemistry of the upper troposphere has been modeled by Arnold et al.² and shown to be significant. Additional quantum yield studies are desired at atmospherically relevant photolysis wavelengths, >290 nm, as a function of pressure and temperature to reduce uncertainties in model calculations.

D27. CH₃C(O)CH₂O₂ (acetonylperoxy radical)

[Back to Index](#)

(1)

(Recommendation: 10-6, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of the acetonylperoxy radical, CH₃C(O)CH₂O₂, has been measured at room temperature by Cox et al.,² Bridier et al.,¹ and Nielsen et al.³ The spectra from Cox et al.² and Nielsen et al.³ are in good agreement but differ significantly from the spectrum reported by Bridier et al.¹ The spectrum reported by Cox et al.² and Nielsen et al.³ exhibit two absorption features in the 200–340 nm region; a strong band at wavelengths <260 nm and a fairly weak band centered at 300 nm. Nielsen et al.³ determined the cross section of the acetonylperoxy radical at 240 nm to be $(2.03 \pm 0.22) \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1}$ relative to the well-established absorption cross section of CH₃O₂. The cross sections of Cox et al.,² renormalized to the absolute value at 240 nm of Nielsen et al.,³ are recommended and listed in Table 4D-27.

Photolysis Quantum Yields and Product Studies: No recommendation.

D28. CH₃C(O)C(O)H (methylglyoxal, MGLY)

[Back to Index](#)

CH ₃ C(O)C(O)H + hν	→ CH ₃ CO + HCO	305 kJ mol ⁻¹	422 nm	(1)
	→ CH ₄ + 2CO	-25 kJ mol ⁻¹	All	(2)
	→ CH ₃ CHO + CO	-6 kJ mol ⁻¹	All	(3)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV/vis absorption spectrum of methylglyoxal (MGLY), CH₃C(O)C(O)H, has been measured at room temperature by Plum et al.⁵ (230–470 nm), Meller et al.⁴ (218–494 nm), Chen et al.¹ (290–440 nm), and Staffebach et al.⁷ (205–474 nm). The absorption spectrum exhibits two absorption bands, a slightly structured band between 225 and 335 nm and a stronger band between 335 and 475 nm, which is highly structured in the region above 410 nm. A steep increase of the absorption cross sections was observed at shorter wavelengths going from 225 to 200 nm by Staffebach et al.⁷

The room temperature values of Meller et al.⁴ and Staffebach et al.⁷ are in good agreement at wavelengths >230 nm. In the weaker absorption band the data of Meller et al.⁴ are greater by up to 10–15%. In the strong absorption band up to 400 nm, the data of Staffebach et al.⁷ are greater by up to ~10% than the data of Meller et al.⁴ and at higher wavelengths the peak values reported by Meller et al.⁴ are higher (due to the higher resolution used in their study) than those measured by Staffebach et al.⁷ The data points of Chen et al.¹ determined at 10 nm intervals fit well to the absorption curves of Meller et al.⁴ and Staffebach et al.⁷ except at 380 and 400 nm where the differences are ~20%. The cross sections reported by Plum et al.⁵ are approximately only the half of the cross sections reported Meller et al.⁴ and Staffebach et al.⁷ The recommended absorption cross sections in Table 4D-28 are from Staffebach et al.⁷ in the region 200–218 nm, the mean of the values from Meller et al.⁴ and Staffebach et al.⁷ in the region 219–235 nm, and averages over 1 nm intervals of the data from Meller et al.⁴ in the region 236–493 nm.

The temperature dependence of the absorption spectrum is relatively weak with differences on the order of 10% observed in the spectra measured by Staffebach et al.⁷ at 298 and 248 K. The largest changes occur in the structured region between 410 and 450 nm where the fine structure becomes more pronounced at lower temperatures.

Photolysis Quantum Yield and Product Studies: Quantum yields have been measured in several studies. Kyle and Orchard³ reported products formed in the photolysis of methylglyoxal at 387 K and 436 nm. Staffebach et al.⁷ measured the products after photolysis of dilute mixtures of methylglyoxal in air using a Xe arc equipped with different band pass filters to isolate several regions of the spectrum. The observed products (CO, CO₂, HCHO, CH₃COOH, CH₃COOOH, CH₃OH and HCOOH,) led to the conclusion that only channel (1) is important in the photolysis range 240–480 nm. Quantum yields were derived by modeling the products formed using a number of secondary radical reactions. At 760 Torr, the Φ₁ yields were: 0.005 for the wavelength region 410–418 nm, 0.055 for 355–480 nm, 0.07 for 280–240 nm and 0.14 for 240–420 nm. Raber and Moortgat⁶ irradiated methylglyoxal in air at different total pressures using two types of broadband lamps and determined the products (CO, CO₂, HCHO, CH₃OOH, CH₃OH, HCOOH, CH₃CHO, CH₃COOH, CH₃COOOH and CH₃COCOOH). The quantum yield derived by modeling the products of the photolysis in the 275–380 nm region varied from 0.94 ± 0.04 at 54 Torr to 0.64 ± 0.03 at 760 Torr, and in the 390–470 nm region from 0.41 ± 0.04 to 0.23 ± 0.02.

Koch and Moortgat² determined the quantum yields of CO, HCHO and CH₃CHO formation at 298 K as a function of wavelength (260–440 nm) and pressure of synthetic air (30–900 Torr) using “broad” monochromatic light, with an optical resolution of 8.5 nm. For photolysis in the 260–320 nm band, the overall quantum yield was found to be unity, independent of wavelength and pressure. The analysis of the data gave evidence that channel (1) is the predominant photolysis path. In the 380–440 nm band the quantum yield of CO showed a Stern-Volmer pressure dependence and the quantum yield of H₂CO increased with increasing

methylglyoxal pressure, which was attributed to the reaction of excited methylglyoxal with ground state methylglyoxal.

The quantum yield of channel (1) over the wavelength range 250–500 nm was expressed as:

$$1/\Phi_1(\lambda) = 1/\Phi_0(\lambda) + P(\text{Torr}) / k(\lambda)$$

where

$$\Phi_0(\lambda) = 1 \text{ for } \lambda < 380 \text{ nm}$$

$$\Phi_0(\lambda) = (8.15 \pm 0.7) \cdot 10^{-9} [\exp(7131 \pm 267) / \lambda] \quad \text{for } \lambda > 380 \text{ nm}$$

$$k(\lambda) = (7.34 \pm 0.1) \cdot 10^{-9} [\exp(8793 \pm 300) / \lambda]$$

Chen et al.¹ used a tunable dye laser to photolysed methylglyoxal at 10 nm intervals over the range 290–440 nm combined with detection of the primary HCO radical photolysis product using cavity ring-down spectroscopy. The HCO quantum yield was calibrated against HCO produced in the photolysis of HCHO or Cl₂/HCHO mixtures. They report the HCO quantum yield to be unity in the wavelength range 320–360 nm, 0.82 ± 0.06 at 290 nm, and to decrease at wavelengths >370 nm to a value of 0.17 ± 0.02 at 440 nm. The HCO quantum yields were reported to be independent of pressure between 290 and 370 nm for the pressure range 10–400 Torr N₂ but to have a Stern-Volmer pressure dependence at wavelengths ≥ 380 nm given by:

$$1/\Phi_1(\lambda) = 1/\Phi_0(\lambda) + k_Q(\lambda) P(\text{Torr})$$

where

$$\Phi_0(\lambda) = (3.63 \pm 0.32) \times 10^{-7} [\exp(5693 \pm 533) / \lambda]$$

and

$$k_Q(\lambda) = (1.93 \pm 0.24) \times 10^4 [\exp(-(5639 \pm 497) / \lambda)]$$

The zero pressure quantum yields, $\Phi_0(\lambda)$, are in good agreement for wavelengths ≤ 420 nm. However, the quantum yields at 760 Torr from the Chen et al.¹ and Koch and Moortgat² expressions deviate by a factor 4 for wavelengths ≥ 420 nm. The data from the more direct study by Chen et al.¹ are recommended. Additional measurements are needed to establish the quantum yields in the long wavelength tail of the spectrum at atmospherically relevant pressures.

D29. CH₃C(O)CH₂OH (hydroxyacetone, acetol)[Back to Index](#)

CH ₃ C(O)CH ₂ OH + hv	→ CH ₃ C(O) + CH ₂ OH	376 kJ mol ⁻¹	318 nm	(1)
	→ HOCH ₂ C(O) + CH ₃	376 kJ mol ⁻¹	318 nm	(2)
	→ HOCH ₂ + CO + CH ₃	335 kJ mol ⁻¹	357 nm	(3)
	→ HO + CH ₂ C(O)CH ₃	335 kJ mol ⁻¹	357 nm	(4)

(Recommendation: 25-1, Note: 25-1, Evaluated: 25-1)

Absorption Cross Sections: The absorption cross sections of CH₃C(O)CH₂OH (hydroxyacetone, acetol) have been measured by Meller and Crowley⁵ (207–333 nm) at 296 K; by Orlando et al.⁷ (235–340 nm) at 298 K by Butkovskaya et al.² (240–350 nm) at 294 K using a static method, and at 328 K over the range 250–350 nm using a dynamic method; and by Messaadia et al.⁶ (200–360 nm) at 298 K and at 250 and 273 K over the range 200–320 nm. Dillon et al.⁴ measured the cross section at 184.9 nm and 358 K to be $(5.4 \pm 0.1) \times 10^{-18}$ cm² molecule⁻¹, whereas Baasandorj et al.¹ reported a value of $(5.43 \pm 0.08) \times 10^{-18}$ cm² molecule⁻¹ at 298 K, which implies no cross section temperature dependence at 184.9 nm within the precision of the measurements. The spectrum shows an absorption band with the maximum near 266 nm. The shape of the measured spectra are in excellent agreement except for the spectrum obtained by Butkovskaya et al.² using the dynamic method. The maxima cross sections reported by Butkovskaya et al.² are 15% and 24% lower for the static and dynamic methods, respectively, than the values obtained by Orlando et al.⁷; the maximum reported by Meller and Crowley⁵ is 11% lower than that of Orlando et al.⁷ Large discrepancies between the measured spectra exist at $\lambda > 310$ nm.

Table 4D-29 lists the recommended absorption cross sections at 298 K between 200 and 335 nm (see footnote). The spectrum temperature dependence is not well defined by the available data and no recommendation is made.

Photolysis Quantum Yield and Product Studies: Quantum yields for removal of hydroxyacetone were estimated by Orlando et al.⁷ to be 0.65 ± 0.25 for the photolysis in the 240–420 nm band. They also suggested that $0.3 \pm 0.2 < \Phi_1 + \Phi_2 < 0.6$ for wavelengths greater than 290 nm. Products detected were CO, CO₂, CH₂O, CH₃C(O)OH, CH₃C(O)O₂H, HC(O)OH, and CH₃OH. These authors concluded that at most 50% of the photolysis occurred via channel (1). Direct observation of OH radicals, presumably arising from channel (4), was made by Chowdhury et al.³ at 148 nm. Photolysis of hydroxyacetone at 193 nm was performed by Chowdhury et al.³ and appears to occur by process (2) with the initial formation of HOCH₂CO yielding OH and ketene.

Table 4D-29. Absorption Cross Sections of CH₃C(O)CH₂OH at 298 K

D30. CH₂=CHCHO (propenal, acrolein)

[Back to Index](#)

CH ₂ =CHCHO + hν	→ CH ₂ =CH + HCO	–	–	(1)
	→ C ₂ H ₄ + CO	162 kJ mol ⁻¹	741 nm	(2)
	→ CH ₂ =CHCO + H	393 kJ mol ⁻¹	305 nm	(3)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The VUV/UV/vis absorption spectrum of acrolein (CH₂=CHCHO, propenal) has been measured at room temperature by Gardner et al.¹ (227–380 nm), Magneron et al.³ (192–431 nm), and Lee et al.² The UV spectrum displays a broad absorption band between 250 and 400 nm, which is structured at wavelengths above 360 nm. The results of both studies agree to within 10% between 298 and 370 nm (with a few exceptions at 352, 360, 362 and 368 nm). Below 298 nm the differences increase up to ~40% with decreasing wavelength, above 368 nm the differences increase with increasing wavelength up to ~100%. The recommended absorption cross sections in Table 4D-30 are the 2 nm averages from the high resolution data of Magneron et al.³

Photolysis Quantum Yield and Product Studies: The photodecomposition of CH₂=CHCHO was studied by Gardner et al.¹ at 313 and 334 nm over the pressure range 26–760 Torr air. They found photolysis at high pressures to be very inefficient at both wavelengths, but the photolysis quantum yield to increase at low pressure. At 313 nm the quantum yield for photodissociation Φ_d of acrolein was 0.0065 at 1 atm and 0.081 at 26 Torr. The pressure dependence was described by:

$$1/(\Phi_d - 0.004) = 0.086 + 1.613 \times 10^{-17} [\text{M}]$$

for concentrations (M) between 8×10^{17} and 2.6×10^{19} molecule cm⁻³. The major products observed were CO and C₂H₄. Magneron et al.³ used broadband photolysis (275–380 nm) of dilute mixtures of acrolein in air to study CH₂=CHCHO photodissociation but did not observe any products using long-path FTIR spectroscopy. An effective quantum yield for photolysis Φ_{eff} ≤ 0.005 nm was measured by Magneron et al.³ in an outdoor smog chamber.

D31. C₂H₅C(O)OH (propionic acid)[Back to Index](#)

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The absorption spectrum of propionic acid, C₂H₅C(O)OH, and the propionic acid dimer, (C₂H₅C(O)OH)₂, have been measured by Hintze et al.¹ (195–220 nm) at 283, 303 and 338 K and Vicente et al.³ (115–257 nm) at 313 K. The spectrum has a strong absorption band in the region 115–192 nm and a weaker band in the region 192–248 nm with a broad maximum near 207 nm. Hintze et al.¹ determined the absorption cross section for the monomer at 206.1 nm and 297 K to be $(1.52 \pm 0.16) \times 10^{-19}$ cm² molecule⁻¹. The dimer cross section at 208.1 nm was determined to be $(3.24 \pm 0.22) \times 10^{-19}$ cm² molecule⁻¹. Absorption cross sections have also been measured at 298 and 356.2 K and 222 nm by Singleton et al.² These investigators obtained absorption cross sections of 12.2×10^{-20} cm² molecule⁻¹ at 298 K and 10.6×10^{-20} cm² molecule⁻¹ at 356.2 K for the monomer and derived absorption cross sections of 10.6×10^{-20} cm² molecule⁻¹ at 298 K and 25.6×10^{-20} cm² molecule⁻¹ at 356.2 K for the dimer by an extrapolation procedure.

Photolysis Quantum Yield and Product Studies: Quantum yields for the formation of OH radicals at 222 nm have been measured by Singleton et al.² to be 0.148 ± 0.90 and 0.341 ± 0.014 for the monomer at 297.6 and 375.0 K, respectively, and 0.018 ± 0.06 at 297.6 K for the dimer (an OH quantum yield of zero for the dimer was assumed at elevated temperatures).

D32. CH₃C(O)C(O)OH (pyruvic acid)[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of pyruvic acid, CH₃C(O)C(O)OH, has been measured at room temperature by Horowitz et al.² (250–410 nm, 0.25 nm resolution) and Mellouki and Mu³ (290–380 nm). An absorption spectrum of pyruvic acid has also been reported by Yamamoto and Back⁷ (250–400 nm) at 358 K. The continuous absorption band between 275–400 nm peaks near 350 nm and contains significant diffuse vibrational band structure. Absolute cross sections for the relative spectrum reported by Yamamoto and Back⁷ were given in Horowitz et al.² following normalization of the spectrum at 350 nm to 3.82×10^{-20} cm² molecule⁻¹. The general shapes of the reported spectra are qualitatively similar although the spectrum reported by Yamamoto and Back⁷ is red shifted and the cross sections at wavelengths <300 nm are considerably greater. This difference in cross section may in part be ascribed to the effect of temperature on the spectrum. The cross sections measured by Mellouki and Mu³ are systematically greater than those obtained by Horowitz et al.² The difference reaches a factor of two for wavelengths <295 nm and is ~20–30% between 305 and 370 nm. These differences are most likely due to the difficulties in handling the pyruvic acid sample and determining its concentration. The recommended absorption cross sections in Table 4D-32 are 1 nm averages from Horowitz et al.² in the range 252–285 nm, the mean of the data from Horowitz et al.² and Mellouki and Mu³ (both 1 nm averages) in the range 290–380 nm, and the data from Horowitz et al.² in the range 385–399 nm.

Photolysis Quantum Yield and Product Studies: Moortgat⁴ reported an effective quantum yield for pyruvic acid photodissociation under atmospheric conditions from a study in an outdoor photoreactor to be 0.43 ± 0.07 . Vesley and Leermakers⁵ reported quantum yields of CO₂ of 1.02 ± 0.06 and of CH₃CHO of 0.6 for photolysis at 366 nm. Yamamoto and Back⁷ measured quantum yields of CO₂ of 0.9 ± 0.1 and CH₃CHO of 0.45 at 366 nm and 340 K. The CH₃CHO yields obtained for 320 and 345 nm photolysis were more variable. Berges and Warneck¹ measured the quantum yields of CH₃CHO, CO₂ and CH₃COOH at 350 nm to be 0.48 ± 0.01 , 1.27 ± 0.18 and 0.14, respectively. In the presence of NO₂, the quantum yield of CH₃CHO was reduced to 0.30 ± 0.04 and PAN was formed with a quantum yield of 0.15 ± 0.02 . Berges and Warneck¹ established $\Phi_1 = 0.48 \pm 0.01$ and $\Phi_2 = 0.39 \pm 0.10$. Mellouki and Mu³ used a laser flash photolysis system at 355 nm and observed the formation of OH originating via channel (4) with a quantum yield of $\Phi_4 = 0.05 \pm 0.03$. The analysis of the products CH₃CHO, CO, CH₃COOH by Winterhalter et al.⁶ are consistent with the data of Berges and Warneck¹ and lead to a quantum yield of channel (3) $\Phi_3 = 0.08 \pm 0.03$. For the photolysis of pyruvic acid at 366 nm the following quantum yields are recommended $\Phi_1 = 0.48 \pm 0.01$, $\Phi_2 = 0.39 \pm 0.10$, $\Phi_3 = 0.08 \pm 0.03$ and $\Phi_4 = 0.05 \pm 0.03$.

D33. HC(O)OC₂H₅ (ethyl formate)[Back to Index](#)

(1)

(Recommendation: 25-1, Note: 25-1, Evaluated: 25-1)

Absorption Cross Sections: The UV absorption spectrum of ethyl formate, $\text{HC(O)OC}_2\text{H}_5$, has been measured at room temperature by McMillan¹ (201–260 nm), Vésine and Mellouki³ (211–260 nm) and Smialek et al.² (114.5–260 nm). The spectrum exhibits a structured absorption band with the maximum near 215 nm. The data sets agree, to within ~15% from 210 to 240 nm, with the data of Vésine and Mellouki being systematically smaller near the spectrum peak. The recommended absorption cross sections in Table 4D-33 are the high resolution (0.04 nm) data of Vésine and Mellouki averaged over 1 and 2 nm intervals in the ranges 211–230 and 230–260 nm, respectively.

A Lyman- α (121.567 nm) cross section of $4 \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$ from Smialek et al., the only study available, is recommended. An uncertainty factor of 1.5 (2σ) is assigned.

Photolysis Quantum Yield and Product Studies: No recommendation.

D34. $\text{CH}_3\text{C(O)CH}_2\text{CH}_3$ (2-butanone, methyl ethyl ketone, MEK)

[Back to Index](#)

(New)

Absorption Cross Sections: UV absorption cross sections of $\text{CH}_3\text{C(O)C}_2\text{H}_5$ (methyl ethyl ketone) have been measured at room temperature by Brewer et al.² (200–335 nm), Chen and Venables³ (335–376 nm), Hynes et al.⁵ (253.7, 260–360 nm), Ito et al.⁶ (165–200 nm, graphical data), Martinez et al.⁷ (202–355 nm), Nádasdi et al.⁸ (221–351 nm), Raber and Moortgat⁹ (277 nm), Rajakumar et al.¹⁰ (184.9 nm), Schneider and Moortgat¹¹ (196–365 nm), and Yujing and Mellouki¹² (240–343 nm), and at 323 K by Doner et al.⁴ (125–240 nm). Temperature dependent cross sections have been measured over the range 242–320 K by Brewer et al.² (200–335 nm), 261–362 K by Hynes et al.⁵ (300–340 nm), and 253–363 K by Nádasdi et al.⁸ (221–351 nm).

The room temperature values of Brewer et al., Hynes et al., Martinez et al., Nádasdi et al., Raber and Moortgat, Schneider and Moortgat, and Yujing and Mellouki are in excellent agreement between 230–320 nm. The Doner et al. cross sections are higher than these other studies by more than an order of magnitude over most of the overlapping wavelength range from 200–240 nm; however, there is much better agreement between the studies of Doner et al., Ito et al., and Rajakumar et al. at wavelengths <200 nm. At wavelengths >335 nm, the reported cross sections of Chen and Venables, Hynes et al., Martinez et al., Nádasdi et al., Schneider and Moortgat, and Yujing and Mellouki diverge. The recommended cross sections given in Table 4D-34 are 2 nm interval data from Brewer et al. (reported every 1 nm) between 200–334 nm and 2 nm interpolated data of Chen and Venables (reported approximately every 0.12 nm) between 336–340 nm. Estimated uncertainty factors (2σ) of 1.3 for $\lambda = 200$ –206 nm, 1.08 for $\lambda = 208$ –328 nm, and 1.2 for $\lambda = 330$ –340 nm are recommended.

Photolysis Quantum Yield and Product Studies: Raber and Moortgat found the quantum yield for photolysis of $\text{CH}_3\text{C}(\text{O})\text{C}_2\text{H}_5$ over the range 275–380 nm to be 0.34 at 1 atm and 0.89 at 51 Torr, with channel (2) being dominant (80–90%). Photodissociation quantum yields of $\text{CH}_3\text{C}(\text{O})\text{C}_2\text{H}_5$ at specific wavelengths have been reported by Baeza-Romero et al.¹ (308 and 320 nm), Nádasdi et al.⁸ (248 and 308 nm), and Rajakumar et al.¹⁰ (248 nm). There is general agreement between the studies that the photodissociation quantum yield varies with wavelength and has a negative pressure dependence and a positive temperature dependence. All studies agree that channel (2) is the most important. At 308 nm, the quantum yield values as a function of temperature and pressure in Table 2 of Nádasdi et al. are recommended.

Table 4D-34. Recommended Absorption Cross Sections of $\text{CH}_3\text{C}(\text{O})\text{CH}_2\text{CH}_3$ (methyl ethyl ketone) at 298 K

D35. CH₂=C(CH₃)CHO (2-methylpropenal, methacrolein, MACR)

[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The VUV/UV absorption spectrum of methacrolein (2-methylpropenal, MACR), CH₂=C(CH₃)CHO, has been measured using diode array spectroscopy at room temperature by Meller (237–391 nm) (see Keller-Rudek et al.³), Raber and Moortgat⁵ (331 nm), Gierczak et al.² (214, 250–395 nm), and Lee et al.⁴ The spectrum exhibits a broad absorption band between 250 and 390 nm with vibrational structure above 310 nm. A detailed vibrational-electronic analysis was reported by Birge et al.¹ The reported spectra are in very good agreement in the region 261–351 nm where the agreement is between ~1 and 10%. At shorter wavelengths, <260 nm, the differences increase to nearly 100% at 250 nm and the cross sections from Gierczak et al.² are consistently greater than those of Meller³ and Raber and Moortgat.⁵ The cross sections at the peaks in the structured region reported by Meller and Raber and Moortgat are consistently higher than those measured by Gierczak et al. presumably due to the higher resolution used. At the band maximum, Raber and Moortgat reported σ(330.7 nm) = 7.64 × 10⁻²⁰ cm² molecule⁻¹ and Gierczak et al. reported σ(331 nm) = 7.2 × 10⁻²⁰ cm² molecule⁻¹. Gierczak et al. also reported σ(213.86 nm) = (2.21 ± 0.11) × 10⁻¹⁷ cm² molecule⁻¹ (Zn lamp source). The 1 nm averages of the results from Gierczak et al. and Meller are generally (with a few exceptions) within 20% of each other for wavelengths up to 376 nm. Above 380 nm, the results of Gierczak et al. are larger with increasing wavelength by up to nearly 80% than the results of Meller. A wavelength shift of ~1 nm toward longer wavelengths can be observed above 340 nm in the absorption spectrum of Gierczak et al. when compared to the spectrum reported by Meller. The recommended absorption cross sections listed in Table 4D-35 are from Gierczak et al.²

Photolysis Quantum Yield and Product Studies: The photodissociation quantum yield for CH₂=C(CH₃)CHO at atmospherically relevant wavelengths is low. Quantum yields were measured by Raber and Moortgat⁵ using broad band photolysis in the wavelength range 275–380 nm, and determination of the stable products (CO, CO₂, HCHO, C₂H₄, C₃H₆, C₂H₂) by FTIR spectroscopy. An upper limit of 0.05 was reported at 760 Torr. Gierczak et al.² used GC and GC-MS detection of photolysis end-products to determine CH₂=C(CH₃)CHO quantum yields at 308 nm of 0.008 ± 0.001 and 0.005 ± 0.001 at 25 and 650 Torr total pressure, respectively. At 351 nm they reported quantum yields of 0.005 ± 0.002 and 0.003 ± 0.001 at 25 and 650 Torr, respectively. A value of Φ < 0.01 is recommended for wavelengths >308 nm.

D36. CH₃C(O)C(O)CH₃ (biacetyl)[Back to Index](#)

(New)

Absorption Cross Sections: UV absorption cross sections of CH₃C(O)C(O)CH₃ (biacetyl) have been measured by Horowitz et al.² (205.4–494 nm), Plum et al.³ (230.6–472.5 nm), and Rajakumar et al.⁴ (184.9 nm) at room temperature, and by Doner et al.¹ (125–240 nm) at 323 K. The reported values of Horowitz et al. and Plum et al. are generally in good agreement over the wavelength range 230–465 nm with the exception of the Plum et al. values being significantly greater (by as much as a factor of 2) in the 315–350 nm range, where a local minimum between the broad absorption bands occurs. The Doner et al. cross sections are higher than the Horowitz et al. and Plum et al. values by approximately an order of magnitude in the vicinity of 230 nm where the measurement wavelengths overlap. The Doner et al. results are not considered in the recommendation. The recommended cross sections given in Table 4D-36 are from Horowitz et al. and are 4 nm values from their data (reported every 1 nm) between 206–490 nm. Estimated uncertainty factors (2σ) of F(λ) = 1.2 + 5 × 10⁻²³/σ(λ) are recommended.

Photolysis Quantum Yield and Product Studies: Rajakumar et al.⁴ reported the 248 nm quantum yield for CH₃CO formation to be pressure dependent with values of 0.76 at 61 Torr up to 0.96 at 643 Torr. Plum et al.³ reported an average quantum yield for biacetyl photolysis of 0.16 for wavelengths ≥290 nm. Based on the study of Rajakumar et al., a quantum yield for channels 1 plus 2 of 0.76 is recommended at 248 nm for pressures 61 Torr and below.

D37. $\text{CH}_3\text{C}(\text{O})\text{CH}=\text{CH}_2$ (methyl vinyl ketone, MVK)

[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of methyl vinyl ketone (MVK), $\text{CH}_3\text{C}(\text{O})\text{CH}=\text{CH}_2$, has been measured at room temperature by Schneider and Moortgat (240–398 nm) (see Keller-Rudek et al.⁴), Raber and Moortgat⁵ (235–400 nm), Fahr et al.² (160–260 nm), and Gierczak et al.³ (216.86 nm and 250–395 nm). The absorption band peaking at ~330 nm displays some weak vibrational band structure, which is superimposed on a continuum envelope. A detailed vibrational-electronic analysis was reported by Birge et al.¹ The cross sections from Schneider and Moortgat are somewhat smaller around the band maximum at 334 nm (agreement within ~10% between 290 and 365 nm), and larger by up to 50% and smaller by up to ~60% in the short- and long-wavelength tails, respectively, than the results of Gierczak et al.³ Gierczak et al.³ reported $\sigma(213.86 \text{ nm}) = (6.6 \pm 0.04) \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$ (Zn lamp source). They also measured the spectrum at reduced temperatures (range 250–298 K), and observed a small increase in the peak cross section of <2% at 250 K. Fahr et al.² reported $\sigma(193 \text{ nm}) = (3.2 \pm 0.2) \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$. The recommended absorption cross sections in Table 4D-37 are taken from Gierczak et al.³

Photolysis Quantum Yield and Product Studies: Product quantum yields were measured by Raber and Moortgat⁵ using broadband photolysis in the range 275–380 nm combined with FTIR monitoring of the stable photolysis products (major CO, C_3H_6 and HCHO; minor CO_2 , HCOOH, CH_3OH , CH_3COOH). They report a pressure dependent quantum yield with $\Phi = 0.05$ at 760 Torr and $\Phi = 0.12$ at 54 Torr. Fahr et al.² used laser photolysis at 193.3 nm and measured the direct formation of CH_3 radicals at 216.4 nm and final products. They report a quantum yield close to unity for the formation of CH_3 and $\text{CH}=\text{CH}_2$ radicals. Gierczak et al.³ measured quantum yields for photolysis at 308, 337, and 351 nm by monitoring the disappearance of MVK. They reported $\Phi = 0.16$ at 25 Torr and $\Phi = 0.04$ at 760 Torr at 308 nm, $\Phi = 0.04$ at 25 Torr and $\Phi = 0.01$ at 760 Torr at 337 nm; and $\Phi = 0.01$ independent of pressure at 351 nm. The quantum yield data were fit to the empirical Stern-Volmer type expression:

$$\Phi(\lambda, P) = \exp[-0.055(\lambda - 308)] / (5.5 + 9.2 \times 10^{-19} [M])$$

where λ is in nm and $[M]$ in molecule cm^{-3} . This parameterization is recommended.

Table 4D-37. Recommended Absorption Cross Sections of CH₃C(O)CH=CH₂ at 298 K

D38. C₂H₂(CO)₂O (maleic anhydride, 2,5-furandione)[Back to Index](#)

(New)

Absorption Cross Sections: UV absorption cross sections of C₂H₂(CO)₂O (maleic anhydride) have been measured at 420 K by Back and Parsons¹ (250–360 nm, graphical data) and at room temperature by Marshall et al.² (200–360 nm). In the overlapping spectral range of 250–330 nm, the spectra from the two studies generally agree to within 15%, with the cross sections of Marshall et al. being consistently larger. At wavelengths longer than 330 nm, the discrepancy between the studies increases, reaching approximately 60% at 360 nm. The recommended cross sections given in Table 4D-38 are from Marshall et al. and are 2 nm values from their data between 200–360 nm (reported every 0.5 nm). An estimated uncertainty factor (2σ) of 1.2 is recommended.

Photolysis Quantum Yield and Product Studies: Marshall et al.² found the photodissociation quantum yield of C₂H₂(CO)₂O at 248 nm to be 0.85 ± 0.20 independent of pressure, and the products CO, CO₂, and C₂H₂ to be formed with unit molar yield.

Table 4D-38. Recommended Absorption Cross Sections of C₂H₂(CO)₂O (maleic anhydride) at 298 K

D39. CH₂=C(CH₃)CH=CH₂ (2-methyl-1,3-butadiene, isoprene)[Back to Index](#)

(New)

Absorption Cross Sections: UV absorption cross sections of CH₂=C(CH₃)CH=CH₂ (isoprene) have been measured at room temperature by Campuzano-Jost et al.¹ (203–233 nm), Dillon et al.² (184.95, 194–234 nm), Jacobs and Platt³ (173–231 nm, graphical data), Jones and Taylor⁴ (167–228 nm, graphical data), Martins et al.⁵ (116–269 nm), Mui and Grunwald⁶ (258–268 nm, graphical data), Sahay et al.⁷ (261–275 nm), and Wang et al.⁸ (197–235 nm). No temperature-dependent UV cross section data are currently available at atmospherically relevant temperatures. The reported room temperature values of Martins et al. and Dillon et al. agree to within <5% at wavelengths below 226 nm. The values of Wang et al., Campuzano-Jost et al., and Jones and Taylor generally agree with Martins et al. and Dillon et al. to within 10% for the overlapping wavelength regions of the studies, with the exception of Jones and Taylor being significantly lower for wavelengths >218 nm. The study of Jacobs and Platt varies significantly relative to the other five studies in the same wavelength range (typically within 30% but as high as 90% deviation). There are substantial differences between the studies of Martins et al., Mui and Grunwald, and Sahay et al. at wavelengths >260 nm.

The recommended cross sections given in Table 4D-39 are 1 nm values from Martins et al. between 170–258 nm. Higher resolution cross section data (0.1 nm) over a broader wavelength range are available from the Martins et al. study. An estimated uncertainty factor (2σ) of 1.1 is recommended.

The recommended Lyman-α (121.567 nm) cross section is taken from Martins et al. with an estimated uncertainty factor (2σ) of 1.2.

Photolysis Quantum Yield and Product Studies: No recommendation.

D40. CH₃ONO (methylnitrite)

[Back to Index](#)

(Recommendation: 10-6, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections. The UV/vis absorption spectrum of methylnitrite (CH₃ONO) extends over the wavelength range between 190 and 440 nm and has a strong continuous band in the UV (190–300 nm) with a maximum near 214 nm. A sharply banded region exists in the near UV/vis region (300–440 nm) with nine absorption peaks, the strongest at ~339 nm. The spectrum has been measured at room temperature by McMillan,¹ Taylor et al.,⁴ and Maricq and Wallington² while single wavelength absorption measurements have been reported by Napier and Norrish³ at 215 and 339 nm at 298 K and by Wiebe and Heicklen⁵ at 366 nm for temperatures in the range 298–423 K. Good agreement exists among these studies for the shape of the UV part of the spectrum. However, a slight wavelength shift is apparent (up to 4 nm) in the peak absorptions measured by Taylor et al.⁴ and McMillan.¹ Taylor et al.⁴ reported the cross section at the short wavelength band maximum near 215 nm to be $(4.59 \pm 0.58) \times 10^{-18}$ compared to 4.97×10^{-18} by Napier and Norrish,³ 4.2×10^{-18} by McMillan,¹ and 4.47×10^{-18} cm² molecule⁻¹ by Maricq and Wallington.² The cross section of $(3.24 \pm 0.16) \times 10^{-19}$ measured by Taylor et al.⁴ at 339 ± 1 nm is in agreement with the values of 3.4×10^{-19} and 3.1×10^{-19} cm² molecule⁻¹ reported by Napier and Norrish³ and McMillan,¹ respectively. The spectrum measured by Taylor et al.⁴ is recommended and listed in Table 4D-40.

Photolysis Quantum Yields and Product Studies: The quantum yield for the dissociation in the banded region (300–400 nm) was measured by Wiebe et al.⁶ to be $\Phi_1 = 0.76$ at 366 nm.

Table 4D-40. Recommended Absorption Cross Sections of CH₃ONO at 298 K

→ CH ₃ ONO + O(¹ D)	496 kJ mol ⁻¹	241 nm	(8)

(Recommendation: 10-6, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of methylnitrate (CH₃ONO₂) displays a strong continuous band in the region (190–250 nm) and a weaker band in the range (250–345 nm). The spectrum was measured at room temperature by McMillan¹ (201–323 nm), Maria et al.³ (235–305 nm), Taylor et al.⁷ (190–330 nm), Roberts and Fajer⁵ (270–330 nm), Libuda and Zabel² (235–345 nm) and by Rattigan et al.⁴ (220–335 nm) over the range 233–294 K, and Talukdar et al.⁶ (236–334 nm) over the range 240–360 K. Good agreement exists at wavelengths <240 nm between the absorption cross sections measured by Taylor et al.⁷ and Rattigan et al.⁴ In the wavelength range 240–340 nm there is good agreement between the measurements of Roberts and Fajer,⁵ Libuda and Zabel,² Rattigan et al.,⁴ and Talukdar et al.⁶ The values of Taylor et al.⁷ are consistently larger at λ >270 nm. Between 235 and 280 nm the absorption cross sections measured by Talukdar et al.⁶ are nearly independent of temperature but for λ >290 nm the cross sections decrease with decreasing temperature. At 330 nm the cross sections decrease by almost a factor of two between 298 and 240 K. Talukdar et al.⁶ parameterized the absorption cross section temperature dependence using the expression:

$$\sigma(\lambda, T) = \sigma(\lambda, 298 \text{ K}) \times \exp [B(\lambda) (T - 298)]$$

The absorption cross sections measured at 298 K by Taylor et al.⁷ are recommended between 190 and 235 nm and those of Talukdar et al.⁶ in the range 236–344 nm, Table 4D-41. The temperature dependence from Talukdar et al.⁶ is recommended and the B(λ) coefficients are listed in Table 4D-41.

Photolysis Quantum Yields and Product Studies: The photodissociation quantum yield for CH₃ONO₂ to produce NO₂ and CH₃O was measured by Talukdar et al.⁶ to be Φ₁ = 0.91 ± 0.20 at 248 nm. Upper limits for the other channels at 248 nm were determined to be Φ₂ <0.05, Φ₃ <0.005, Φ₄₊₈ <0.1 and Φ₅ <0.015 ± 0.01. It is expected that the quantum yield Φ₁ is unity at wavelengths >248 nm. Oxygen atoms were measured with a quantum yield of 0.65 ± 0.15 at 193 nm and <0.01 at 248 and 308 nm. Yang et al.⁸ studied the photodissociation of jet-cooled CH₃ONO₂ at 193 and 248 nm and found channel (1) to be the principal photolysis product channel with relative yields of 0.7 and 1 at 193 and 248 nm, respectively. They also reported an O(¹D) yield of 0.3 at 193 nm.

Table 4D-41. Recommended Absorption Cross Sections of CH₃ONO₂ at 298 K and Temperature Coefficients

D42. CH₃CH₂ONO₂ (ethyl nitrate)[Back to Index](#)

(New)

Absorption Cross Sections: UV absorption cross sections of C₂H₅ONO₂ (ethyl nitrate) have been measured at room temperature by Clemitshaw et al.¹ (235–340 nm), Higgins et al.² (240–320 nm), Kaya et al.³ (170.6–227.3 nm, graphical data), Roberts⁴ and Roberts and Fajer⁵ (270–330 nm), Talukdar et al.⁶ (236–350 nm), Turberg et al.⁷ (185–330 nm), Wallace-Goodeve⁸ (205.2–319.3 nm, graphical data), and Zhu and Ding⁹ (265–340 nm).

The reported room temperature values of Talukdar et al., Turberg et al., and Zhu and Ding are in excellent agreement between 240–310 nm, with the studies of Clemitshaw et al., Higgins et al., and Roberts and Fajer also generally in good agreement over this range. Near the long wavelength extremes of each respective study, the reported cross sections can deviate significantly high (e.g., Higgins et al. and Clemitshaw et al.) or low (Roberts and Fajer) relative to the other values. The values of Wallace-Goodeve deviate both higher and lower from the other studies, with differences mostly within 15%, but as large as 60%. The study of Kaya et al. is an outlier with values typically 50–100% greater than other studies.

The recommended cross sections given in Table 4D-42 are from the data of Turberg et al. (typically reported every 5 nm) between 185–235 nm, averages of the data of Turberg et al. and Talukdar et al. (reported every 2 nm and interpolated to 5 nm) between 240–320 nm, and 5 nm interpolated data of Talukdar et al. between 325–340 nm. An estimated uncertainty factor (2σ) of 1.15 over the 185–340 nm range is recommended.

Temperature-dependent cross sections have been measured and parameterized to empirical equations over the range 240–360 K by Talukdar et al.⁶ (236–340 nm), over the range 238–298 K by Zhu and Ding⁹ (265–340 nm), and over the range 233–298 K by Clemitshaw et al.¹ (235–335 nm). All three studies are in good agreement. Talukdar et al. parameterized the absorption cross section temperature dependence from 240–360 K using the expression:

$$\sigma(\lambda, T) = \sigma(\lambda, 298 \text{ K}) \times \exp[B(\lambda)(T - 298)]$$

The temperature dependence from Talukdar et al. is recommended and the B(λ) coefficients are listed in Table 4D-42.

Photolysis Quantum Yield and Product Studies: Zhu and Ding⁹ found a quantum yield of 1.0 ± 0.1 for channel (1) at 308 nm, independent of temperature over the narrow temperature range 278–298 K.

Table 4D-42. Recommended Absorption Cross Sections of CH₃CH₂ONO₂ at 298 K and Temperature Coefficients

D43. CH₃O₂NO₂ (methylperoxynitrate)

[Back to Index](#)

(Recommendation: 10-6, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of CH₃O₂NO₂ (methylperoxynitrate) has been measured by Cox and Tyndall² (200–310 nm) at 275 K, Morel et al.³ (200–290 nm) at 296 K, Sander and Watson⁴ (240–280 nm) at 298 K, and Bridier et al.¹ (200–280 nm) at 298 K. The spectrum has a strong absorption band below 225 nm and a moderate band at longer wavelengths. The reported cross sections are in reasonable agreement in the range 230–250 nm but scatter in the cross section data exists at both shorter and longer wavelengths. The recommended cross sections listed in Table 4D-43 are a smoothed average of the data from the four studies.

Photolysis Quantum Yields and Product Studies: No recommendation.

D44. $\text{CH}_3\text{C}(\text{O})\text{O}_2\text{NO}_2$ (peroxyacetyl nitrate, PAN)

[Back to Index](#)

(Recommendation: 06-2, Note 10-6, Evaluated 10-6)

Absorption Cross Sections. The absorption cross sections of $\text{CH}_3\text{C}(\text{O})\text{O}_2\text{NO}_2$ (peroxyacetyl nitrate, PAN) have been measured at room temperature by Stephens¹⁰ (220–450 nm), Senum et al.⁹ (200–300 nm), Basco and Parmar¹ (210–250 nm), and Libuda and Zabel⁶ (219–325 nm) and at 250, 273, and 298 K by Talukdar et al.¹¹ (196–350 nm). The studies are in reasonable agreement. The data of Talukdar et al.¹¹ and Libuda and Zabel⁶ agree within 10% at wavelengths <300 nm. The data of Stephens¹⁰ and Basco and Parmar¹ are greater by up to 20 and 45%, respectively. The Senum et al.⁹ cross sections are systematically less than the data of Talukdar et al.¹¹ Libuda and Zabel⁶ carried out simultaneous UV and IR studies that showed that their measured cross sections needed to be corrected for impurities that are transparent in the UV but contribute to the sample pressure in the absorption cell. The corrections were on the order of 20%. The recommended absorption cross sections listed in Table 4D-44 are taken from Talukdar et al.,¹¹ which are in good agreement with those of Libuda and Zabel⁶ but include a wider spectral coverage and temperature range. The uncertainties in the cross sections are estimated to be of the order of a factor of 2 in the long wavelength region but smaller at shorter wavelengths, decreasing to about 10% at 220 nm.

A systematic decrease of the absorption cross sections with decreasing temperature was observed by Talukdar et al.¹¹ The temperature dependence was parameterized using the expression:

$$\ln \sigma(\lambda, T) = \ln \sigma(\lambda, 298 \text{ K}) + B(\lambda)(T - 298)$$

The temperature coefficients $B(\lambda)$ are listed in Table 4D-44.

Photolysis Quantum Yields and Product Studies. Photolysis quantum yields for the production of NO_2 and NO_3 at 248 nm were reported by Mazely et al.^{7,8}: $\Phi(\text{NO}_2, 248 \text{ nm}) = 0.83 \pm 0.09$ and $\Phi(\text{NO}_3, 248 \text{ nm}) = 0.3 \pm 0.1$. The NO_3 quantum yield was obtained relative to the unity NO_3 quantum yield in the photolysis of N_2O_5 at 248 nm. However, this latter quantum yield was re-measured to be 0.8 ± 0.1 by Harwood et al.,⁴ so that the $\Phi(\text{NO}_3, 248 \text{ nm})$ should be rescaled to 0.24. Quantum yields for the production of NO_3 in the photolysis of $\text{CH}_3\text{C}(\text{O})\text{O}_2\text{NO}_2$ at 248 and 308 nm were also measured by Harwood et al.⁵: $\Phi(\text{NO}_3, 248 \text{ nm}) = 0.19 \pm 0.04$ and $\Phi(\text{NO}_3, 308 \text{ nm}) = 0.41 \pm 0.10$. Flowers et al.² studied the photolysis of PAN at 289 nm and detected NO_3 using cavity ring-down spectroscopy. They obtained $\Phi(\text{NO}_3, 289 \text{ nm}) = 0.31 \pm 0.08$ relative to the unity NO_3 quantum yield in the photolysis of N_2O_5 at that wavelength. In a second study, Flowers et al.³ measured the wavelength dependence of $\Phi(\text{NO}_3)$: at 294 nm (0.29 ± 0.07), 299 nm (0.28 ± 0.07), 308 nm (0.28 ± 0.05), and 312 nm (0.39 ± 0.07). These results indicate that between 289 and 308 nm the NO_3 quantum yield is nearly constant with $\Phi(\text{NO}_3) = 0.29 \pm 0.07$. An increase of $\Phi(\text{NO}_3)$ at longer wavelengths cannot be ruled out. The recommended quantum yields are $\Phi(\text{NO}_2) = 0.7$ and $\Phi(\text{NO}_3) = 0.3$ for $\lambda > 300 \text{ nm}$.

D45. C₂H₅C(O)O₂NO₂ (peroxypropionyl nitrate, PPN)

[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The absorption cross sections of C₂H₅C(O)O₂NO₂ (peroxypropionyl nitrate, PPN) have been measured at room temperature by Senum et al.² (200–300 nm) and at 253, 273, and 296 K by Harwood et al.¹ (210–340 nm). The absorption spectrum shows monotonically decreasing absorption cross sections with increasing wavelength over the range 200–340 nm. The absorption cross sections reported by Harwood et al.¹ are larger than those reported by Senum et al.² over the common wavelength range by ~10% at 210 nm up to ~30% at 300 nm. A wavelength dependent systematic decrease of the absorption cross sections with decreasing temperature was reported by Harwood et al.¹ The temperature dependence was parameterized to the empirical expression:

$$\ln \sigma(\lambda, T) = \ln \sigma(\lambda, 296 \text{ K}) + B(\lambda)(T - 296)$$

The recommended absorption cross sections and temperature coefficients in Table 4D-45 are taken from Harwood et al.¹

Photolysis Quantum Yield and Product Studies: Quantum yields for the production of NO₃ in the photolysis of C₂H₅C(O)O₂NO₂ at 248 and 308 nm were measured by Harwood et al.¹ to be Φ₂(248 nm) = 0.22 ± 0.04 and Φ₂(308 nm) = 0.39 ± 0.04.

D46. HCN (hydrogen cyanide)

[Back to Index](#)

(Recommendation 25-1, Note: 25-1, Evaluated: 25-1)

Absorption Cross Sections: The VUV absorption spectrum of hydrogen cyanide, HCN, has been reported by McPherson and Simons³ (131.22–145.73 nm, graphical data), Lee² (105–154.34 nm, graphical data), Nagata et al.⁴ (112.39, 80.6–129.63 nm), and Nuth and Glicker⁵ (62.66–146.92 nm). The Lyman- α (121.567 nm) cross section data from these studies is in poor agreement. A Lyman- α cross section of $4.5 \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$ is recommended with an uncertainty factor of 1.5 (2σ). Herzberg and Innes¹ have reported a vibrational-rotational spectroscopic analysis of the HCN VUV electronic transitions.

Photolysis Quantum Yield and Product Studies: The solar photodissociation rate for HCN is small, even in the upper stratosphere. The photolysis products are expected to be $\text{H} + \text{CN}$.

D47. CH_3CN (methyl cyanide)

[Back to Index](#)

(Recommendation: 82-57, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: Acetonitrile (CH_3CN , methyl cyanide) absorbs weakly at wavelengths $>180 \text{ nm}$ with absorption cross sections $<10^{-20} \text{ cm}^2 \text{ molecule}^{-1}$. Suto and Lee³ (114–178 nm), Zetzsch⁴ (155–185 nm), and Eden et al.¹ (113–320 nm) have reported cross section data. The agreement among the cross section data sets is, however, poor and no cross section recommendation is given.

Photolysis Quantum Yield and Product Studies: McElcheran et al.² studied the photodissociation of CH_3CN at 184.9 nm. On the basis of end-product analysis, channel (1) was identified as the major photolysis pathway.

SECTION 4E. FO_x PHOTOCHEMISTRY

E1. HF (hydrogen fluoride)

[Back to Index](#)

(Recommendation: 06-2, Note: 15-10 Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of hydrogen fluoride, HF, has been measured at 289.5, 326, 373, and 438 K by Safary et al.⁵ and Safary⁴ (153–182 nm) and at room temperature by Nee et al.³ (107–145 nm), Carnovale et al.¹ (8–155 nm), and Hitchcock et al.² (30–200 nm). HF does not absorb significantly at wavelengths >180 nm. On the basis of the Nee et al. VUV spectrum, a Lyman- α (121.567 nm) cross section of $3.1 \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1}$ is recommended.

Photolysis Quantum Yield and Product Studies: Photodissociation should be an unimportant loss process in the stratosphere.

E2. FO₂ (fluoroperoxy radical)

[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The gas-phase UV absorption spectrum of the fluoroperoxy radical, FO₂, has been measured at room temperature by Pagsberg et al.⁶ (206–250 nm; reported in Wayne et al.⁷), Maricq and Szenté⁴ (186–276 nm), Ellermann et al.² (215–254 nm), and at 215 nm by Lyman and Holland.³ In earlier studies, Chegodaev and Tupikov¹ and Matchuk et al.⁵ reported spectra of FO₂ in liquid argon at 87 K. The results from Maricq and Szenté,⁴ Ellermann et al.,² and Lyman and Holland³ are in excellent agreement. The cross sections measured by Pagsberg et al.⁶ are larger by factors of 1.4 to 1.8 between 206 and 245 nm and a factor of 3 at 250 nm. The recommended absorption cross sections in Table 4E-2 are taken from Maricq and Szenté.⁴

Photolysis Quantum Yield and Product Studies: No recommendation.

E3. F₂O (difluorine monoxide)

[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of difluorine monoxide, F₂O, has been measured at 273 K over the wavelength range 210–546 nm by Glissmann and Schuhmacher,¹ the only study available. Their absorption cross section data are recommended and are listed in Table 4E-3.

Photolysis Quantum Yield and Product Studies: No recommendation.

Table 4E-3. Recommended Absorption Cross Sections of F₂O at 273 K

E4. F₂O₂ (dioxygen difluoride)

[Back to Index](#)

(Recommendation: 15-10, Note: 15-10, Evaluated: 10-6)

Absorption Cross Sections: The gas-phase UV/vis absorption spectrum of dioxygen difluoride, F₂O₂, has been measured at 193 K by Chegodaev and Tupikov² (197–260 nm), at 195 K by Matchuk et al.⁵ (350–600 nm), at 273 K by Brodersen et al.¹ (220–522.5 nm), and at 298 K by Lyman and Holland⁴ (215 nm). A measurement of F₂O₂ in liquid freon at 77 K has been reported by Kirshenbaum and Streng³ (200–480 nm). The absorption

spectrum shows decreasing absorption cross sections with increasing wavelength and evidence for several transitions that appear as shoulders in the spectrum. An absorption feature near 405 nm reported by Brodersen et al.¹ does not appear in the spectra reported by Matchuk et al.⁵ and Kirshenbaum and Streng.³ Although measured at significantly different temperatures, the data from Brodersen et al.¹ and Chegodaev and Tupikov² in the wavelength range 220–250 nm agree to within 10–15%, with the Chegodaev and Tupikov data being systematically lower. The recommended absorption cross sections in Table 4E-4 are from Chegodaev and Tupikov² in the region 200–210 nm, Brodersen et al.¹ in the region 220–360 nm, and Matchuk et al.⁵ for the 370–600 nm region.

Photolysis Quantum Yield and Product Studies: No recommendation.

Table 4E-4. Recommended Absorption Cross Sections of F₂O₂ at 193–273 K

λ (nm)	$10^{20} \sigma$ (cm ²)	λ (nm)	$10^{20} \sigma$ (cm ²)	λ (nm)	$10^{20} \sigma$ (cm ²)

E5. FNO (nitrosyl fluoride)

[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of nitrosyl fluoride, FNO, has been measured at room temperature by Burley et al.¹ (180–350 nm) and Pagsberg et al.³ (310.5 nm). Johnston and Bertin² report a cross section at 195 K and 310.5 nm. The FNO spectrum has two similar strength bands centered at 180 nm and 310 nm. The 310 nm band has significant vibronic structure at wavelengths >250 nm. The agreement between the single wavelength measurement of Pagsberg et al.³ and the Burley et al.¹ spectrum is good. The recommended absorption cross sections in Table 4E-5 are at 2 nm intervals for the continuous region of the spectrum (λ <260 nm) and at 1 nm intervals in the structured region (λ >260 nm).

Photolysis Quantum Yield and Product Studies: The quantum yield for decomposition is expected to be unity.

Table 4E-5. Recommended Absorption Cross Sections of FNO at 298 K

E6. CHF₃ (trifluoromethane, HFC-23)[Back to Index](#)

(1)

(Recommendation: 15-10; Note: 15-10; Evaluated: 15-10)

Absorption Cross Sections: Trifluoromethane, CHF₃ (HFC-23), has negligible absorption at wavelengths >190 nm. The VUV absorption spectrum of HFC-23 was measured at 298 K by Sauvageau et al.¹ (62–122 nm) and Suto and Lee² (106–124 nm). The two studies differ by ~50% at Lyman- α (121.567 nm). The recommended Lyman- α cross section is an average of the results from these two studies, 3.5×10^{-19} cm² molecule⁻¹, where the Sauvageau et al. data were linearly interpolated to 121.567 nm. An uncertainty factor of 2 (2 σ) is assigned, which encompasses the results from both studies.

Photolysis Quantum Yield and Product Studies: No recommendation.

E7. CH₂F₂ (difluoromethane, HFC-32)

[Back to Index](#)

(1)

(Recommendation: 15-10; Note: 15-10; Evaluated: 15-10)

Absorption Cross Sections: Difluoromethane, CH₂F₂ (HFC-32), has negligible absorption at wavelengths >190 nm. The VUV absorption spectrum of HFC-32 at 298 K was measured by Sauvageau et al.¹ (60–142 nm; reported in 0.1 to 0.5 nm intervals) and Seccombe et al.² (60–152 nm; reported in ~0.015 nm intervals). The cross sections reported in these studies agree at Lyman- α (121.567 nm) to within ~30%. An average Lyman- α cross section from these studies, $5.5 \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1}$, is recommended. An uncertainty factor of 1.4 (2 σ) is recommended, which covers the range of experimental data.

Photolysis Quantum Yield and Product Studies: No recommendation.

- (1) Sauvageau, P.; Gilbert, R.; Berlow, P. P.; Sandorfy, C. Vacuum ultraviolet absorption spectra of fluoromethanes. *J. Chem. Phys.* **1973**, *59*, 762-765, doi:10.1063/1.1680086.

E8. CHF₂CF₃ (pentafluoroethane, HFC-125)

[Back to Index](#)

(1)

(Recommendation: 15-10; Note: 15-10; Evaluated: 15-10)

Absorption Cross Sections: Pentafluoroethane, CHF₂CF₃ (HFC-125), has negligible absorption at wavelengths >190 nm. The VUV absorption spectrum of HFC-125 has not been reported to date. The recommended Lyman- α cross section of HFC-125 is assumed to be similar to that of CHF₃ (HFC-23) with an estimated value of $3.5 \times 10^{-19} \text{ cm}^2 \text{ molecule}^{-1}$. An uncertainty factor of 3.0 (2 σ) is assigned due to the lack of experimental data.

Photolysis Quantum Yield and Product Studies: No recommendation.

E9. CH₂FCF₃ (1,1,1,2-tetrafluoroethane, HFC-134a)

[Back to Index](#)

(1)

(Recommendation: 15-10; Note: 15-10; Evaluated: 15-10)

Absorption Cross Sections: 1,1,1,2-tetrafluoroethane, CH₂FCF₃ (HFC-134a), has negligible absorption at wavelengths >190 nm. The VUV absorption spectrum of HFC-134a has not been reported to date. The Lyman- α cross section of HFC-134a is expected to be less than that of CH₃CF₃ (HFC-143a) and comparable to that of CH₂F₂ (HFC-32). An estimated value of $5 \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1}$ is recommended. An uncertainty factor of 2.0 (2 σ) is assigned based on the lack of experimental data.

Photolysis Quantum Yield and Product Studies: No recommendation.

E10. CH₃CF₃ (1,1,1-trifluoroethane, HFC-143a)

[Back to Index](#)

(1)

(Recommendation: 15-10; Note: 15-10; Evaluated: 15-10)

Absorption Cross Sections: 1,1,1-trifluoroethane, CH₃CF₃ (HFC-143a), has negligible absorption at wavelengths >190 nm. The VUV absorption spectrum of HFC-143a was measured by Sauvageau et al.¹ between 61 and 132 nm at 298 K with a Lyman- α cross section of $1.75 \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$, which is

recommended. The uncertainty factor for the Lyman- α cross section is assigned a value of 2.0 (2 σ) based primarily on the limited available data.

Photolysis Quantum Yield and Product Studies: No recommendation.

- (1) Sauvageau, P.; Doucet, J.; Gilbert, R.; Sandorfy, C. Vacuum ultraviolet and photoelectron spectra of fluoroethanes. *J. Chem. Phys.* **1974**, *61*, 391-395, doi:10.1063/1.1681649.

E11. CH₃CHF₂ (1,1-difluoroethane, HFC-152a)

[Back to Index](#)

(1)

(Recommendation: 15-10; Note: 15-10; Evaluated: 15-10)

Absorption Cross Sections: 1,1-difluoroethane, CH₃CHF₂ (HFC-152a), has negligible absorption at wavelengths >190 nm. The VUV absorption spectrum of HFC-152a was measured by Sauvageau et al.¹ between 60 and 134 nm at 298 K with a Lyman- α cross section of 3.2×10^{-17} cm² molecule⁻¹, which is recommended. The uncertainty factor for the Lyman- α cross section is assigned a value of 2.0 (2 σ) based primarily on the limited available data.

Photolysis Quantum Yield and Product Studies: No recommendation.

- (1) Sauvageau, P.; Doucet, J.; Gilbert, R.; Sandorfy, C. Vacuum ultraviolet and photoelectron spectra of fluoroethanes. *J. Chem. Phys.* **1974**, *61*, 391-395, doi:10.1063/1.1681649.

E12. CF₄ (carbon tetrafluoride)

[Back to Index](#)

(Recommendation: 90-1, Note: 15-10, Evaluated: 10-6)

Absorption Cross Sections: The VUV spectrum of carbon tetrafluoride, CF₄, consists of a strong absorption band between 6 and 120 nm with several broad features assigned to a Rydberg series with maxima near 54, 68, 78, 90 and 99 nm. The spectrum also has discrete vibrational structure in the region 56 to 63 nm. The absolute absorption cross sections have been studied extensively in the VUV by a number of groups as summarized in Table 4E-12. General agreement (to within a factor of 2) exists in the wavelength range 6–100 nm among the data of Rebbert and Ausloos,¹⁰ Sauvageau et al.,¹¹ Lee et al.,⁷ Cole and Dexter,³ Lee et al.,⁸ Au et al.,¹ Cook and Ching,⁴ Hatherly and Flaxman,⁵ and Chim et al.²

The absorption cross section at Lyman- α (121.567 nm) was reported to be $(5.73 \pm 0.97) \times 10^{-21}$ cm² molecule⁻¹ by Inn,⁶ $<1 \times 10^{-20}$ cm² molecule⁻¹ by Lee et al.,⁸ and $<8 \times 10^{-22}$ cm² molecule⁻¹ by Ravishankara et al.⁹ A value of 5.5×10^{-21} cm² molecule⁻¹ with an uncertainty factor of 2 (2 σ) is recommended for the cross section at Lyman- α .

Photolysis Quantum Yield and Product Studies: No recommendation. CF₄ does not absorb strongly at wavelengths >120 nm and therefore it is not expected to photodissociate until it reaches the mesosphere.

Table 4E-12. Summary of CF₄ Absorption Cross Section Studies

Reference	Year	Wavelength Range (nm)	Temperature (K)

E13. C₂F₆ (hexafluoroethane)

[Back to Index](#)

C₂F₆ + hν → Products

(1)

(Recommendation: 10-6, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The VUV absorption spectrum of hexafluoroethane, C₂F₆, consists of a strong absorption band between 6 and 120 nm with several broad features and maxima near 58, 68, 79, 87 and 93 nm. Absolute absorption cross sections have been reported by Sauvageau et al.⁴ (60–117 nm), Lee et al.² (18–74 nm), and Cole and Dexter¹ (6.5–10.0 nm). The cross section data from Sauvageau et al. over the range 60 to 75 nm are much smaller than those of Lee et al.

The absorption cross section at Lyman-α (121.567 nm) was determined by Ravishankara et al.³ to be $(9.87 \pm 0.35) \times 10^{-21}$ cm² molecule⁻¹, which is recommended.

Photolysis Quantum Yield and Product Studies: No recommendation. C₂F₆ does not absorb significantly at wavelengths >120 nm and therefore it is not expected to photodissociate until it reaches the mesosphere.

- (1) Cole, B. E.; Dexter, R. N. Photoabsorption cross sections for chlorinated methanes and ethanes between 46 and 100 Å. *J. Quant. Spectrosc. Radiat. Transf.* **1978**, *19*, 303-309, doi:10.1016/0022-4073(78)90063-8.

E14. *c*-C₄F₈ (perfluorocyclobutane)[Back to Index](#)

(1)

(Recommendation: 15-10, Note: 15-10, Evaluated: 15-10)

Absorption Cross Sections: The spectrum of perfluorocyclobutane, *c*-C₄F₈, consists of a strong absorption band in the VUV with a maximum at 117 nm and shows further weak absorption bands at 137 and 174 nm up to about 200 nm. The absolute photoabsorption cross sections have been measured at high resolution in the VUV by Limão-Vieira et al.¹ in the range 115–204 nm, although the data in the wavelength range >190 nm is scattered. They estimated a stratospheric photolysis lifetime of ~400 years at 20 km decreasing to a few days at 40–50 km.

The absorption cross section at Lyman- α (121.567 nm) was determined by Limão-Vieira et al.¹ to be $7.98 \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1}$ and Ravishankara et al.² reported a value of $(8.76 \pm 0.49) \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1}$. An average of the Lyman- α cross sections from these studies is recommended, $8.37 \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1}$ with a 1.05 uncertainty factor (2σ), which encompasses the results from both studies.

Photolysis Quantum Yield and Product Studies: No recommendation.

E15. C₅F₁₂ (perfluoropentane)[Back to Index](#)

(1)

(Recommendation: 10-6, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: No absorption spectrum of perfluoropentane, C₅F₁₂, is known. An absorption cross section at Lyman- α (121.567 nm) was determined by Ravishankara et al.¹ to be $(5.32 \pm 0.30) \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1}$, which is recommended.

Photolysis Quantum Yield and Product Studies: No recommendation.

- (1) Ravishankara, A. R.; Solomon, S.; Turnipseed, A. A.; Warren, R. F. Atmospheric lifetimes of long-lived halogenated species. *Science* **1993**, *259*, 194-199, doi:10.1126/science.259.5092.194.

E16. C₆F₁₄ (perfluorohexane)[Back to Index](#)

(1)

(Recommendation: 10-6, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections. No absorption spectrum of C₆F₁₄, perfluorohexane, is known. An absorption cross section at Lyman- α (121.567 nm) was determined by Ravishankara et al.¹ to be $(9.82 \pm 0.53) \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1}$, which is recommended.

Photolysis Quantum Yield and Product Studies: No recommendation.

- (1) Ravishankara, A. R.; Solomon, S.; Turnipseed, A. A.; Warren, R. F. Atmospheric lifetimes of long-lived halogenated species. *Science* **1993**, *259*, 194-199, doi:10.1126/science.259.5092.194.

E17. (CF₃)₂*c*-C₄F₆ (perfluoro-1,2-dimethylcyclobutane)[Back to Index](#)

(1)

(Recommendation: 10-6, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: No absorption spectrum of perfluoro-1,2-dimethylcyclobutane, (CF₃)₂*c*-C₄F₆, is known. An absorption cross section at Lyman- α (121.567 nm) was determined by Ravishankara et al.¹ to be $(1.22 \pm 0.07) \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$, which is recommended. The large cross section implies a local lifetime of only a few days in the mesosphere.

Photolysis Quantum Yield and Product Studies: No recommendation.

- (1) Ravishankara, A. R.; Solomon, S.; Turnipseed, A. A.; Warren, R. F. Atmospheric lifetimes of long-lived halogenated species. *Science* **1993**, 259, 194-199, doi:10.1126/science.259.5092.194.

E18. CF₂O (carbonyl difluoride)

[Back to Index](#)

(Recommendation: 06-2, Note: 15-10, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of carbonyl difluoride (difluorophosgene), CF₂O, has been measured at room temperature by Chou et al.¹ (185–226 nm), Molina and Molina² (186–224 nm), and Nölle et al.³ (199–232 nm). The high resolution spectrum reported by Nölle et al.³ is highly structured. The cross section data from Nölle et al.³ are somewhat larger than those from Molina and Molina² with differences in the averaged values over 500 cm⁻¹ intervals ranging between 1.5 and 22%. The cross section data of Chou et al.¹ are in good agreement with the data from Molina and Molina² in the region 186–197 nm. At longer wavelengths the cross sections from these studies diverge with the Chou et al. results being larger, ~200% near 225 nm. The recommended absorption cross sections in Table 4E-18 are the 500 cm⁻¹ averages of the data from Molina and Molina² in the range 186–199 nm and the data from Nölle et al.³ at longer wavelengths. The recommended uncertainty factor in the room temperature spectrum is 1.30 (2σ) for all wavelengths included in Table 4E-18.

Photolysis Quantum Yield and Product Studies: The photodissociation of CF₂O has been studied by Nölle et al.⁴ at 193, 210, and 220 nm and Molina and Molina² at 206 nm. Nölle et al.⁴ determined the COF + F quantum yields by combining FTIR detection of products with excimer laser photolysis at 193 nm and Hg lamp photolysis at 210 and 220 nm. The “apparent” quantum yields for CF₂O were 0.47 ± 0.03, 0.57 ± 0.05, and 0.11 ± 0.02 at 193, 210 and 220 nm, respectively. In the case of the laser photolysis at 193 nm, where high concentrations of COF are formed, the self-reaction of the COF photodissociation product regenerates CF₂O via COF + COF → CF₂O + CO. Assuming that all COF radicals react quantitatively in this way, the actual quantum yield at 193 nm is 0.94 ± 0.06. The quantum yields at 210 and 220 nm obtained using the Hg lamp photolysis generated much lower COF radical concentrations and are reported as the actual quantum yields. Molina and Molina² report a quantum yield of 0.26 at 206 nm that is considerably lower than reported by Nölle et al.⁴ On the basis of the Nölle et al. study a CF₂O photolysis quantum yield of unity is recommended for wavelengths less than 210 nm.

Table 4E-18. Recommended Absorption Cross Sections of CF₂O at 298 K

λ (nm)	10 ²⁰ σ (cm ²)	λ (nm)	10 ²⁰ σ (cm ²)	λ (nm)	10 ²⁰ σ (cm ²)
186.0	5.5	199.0	1.6	213.9	0.188
187.8	4.8	201.0	1.32	216.2	0.120
189.6	4.2	203.1	0.987	218.6	0.077
191.4	3.7	205.1	0.754	221.0	0.046
193.2	3.1	207.3	0.508	223.5	0.032
195.1	2.6	209.4	0.392	226.0	0.021
197.0	2.1	211.6	0.272	228.6	0.015

Note:

186–199 nm: Molina and Molina²

201–229 nm: Nölle et al.³

E19. COHF (formyl fluoride)[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of formyl fluoride, COHF, has been measured at room temperature by Giddings and Innes¹ (195–255 nm), Meller (194–267 nm) (see Röth et al.³), and Rattigan et al.² (220–267 nm). The high-resolution measurements show the long-wavelength wing of a highly structured absorption band. The absorption cross sections reported by Giddings and Innes¹ are larger by nearly a factor of two than the high resolution (0.016 nm) data reported by Meller using diode array spectrometry. The cross sections measured by Rattigan et al.² at a resolution of 1.2 nm lie between the Giddings and Innes¹ and Meller data sets in the range 220–230 nm and are closer to the data of Giddings and Innes¹ in the region 230–245 nm. Rattigan et al.² found the absorption cross sections to be independent of temperature over the range 233–318 K. The recommended absorption cross sections in Table 4E-19 are averages over 1 nm intervals of the high-resolution data from Meller.

Photolysis Quantum Yield and Product Studies: No recommendation.

Table 4E-19. Recommended Absorption Cross Sections of COHF at 298 K

E20. CF₃O₂ (trifluoromethylperoxy radical)[Back to Index](#)

(1)

(Recommendation: 10-6, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption cross sections of the trifluoromethylperoxy radical, CF₃O₂, have been measured at room temperature by Maricq and Szenté¹ (186–276 nm) and Nielsen et al.² (215–270 nm). The absorption spectrum displays a broad absorption band with a maximum at 210 nm. The cross sections reported by Nielsen et al.² are in good agreement with those measured by Maricq and Szenté¹ in the range 240–270 nm, but are consistently smaller at shorter wavelengths (by 20% at 215 nm). The recommended absorption cross sections listed in Table 4E-20 are taken from Maricq and Szenté.¹

Photolysis Quantum Yield and Product Studies: No recommendation.

E21. CF₃OH (trifluoromethanol)[Back to Index](#)

(Recommendation: 97-4, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: An upper limit of 10⁻²¹ cm² molecule⁻¹ has been determined experimentally by Molina and Molina¹ for the absorption cross sections of trifluoromethanol, CF₃OH, over the wavelength range 185–300 nm. This upper limit is consistent with estimates based on similarities between CF₃OH and CH₃OH, as well as with quantum chemistry calculations reported by Schneider et al.²

Photolysis Quantum Yield and Product Studies: No recommendation.

E22. CH₂FCH₂OH (2-fluoroethanol)[Back to Index](#)

(1)

(New Entry)

Absorption Cross Sections: UV absorption cross sections of CH₂FCH₂OH (2-fluoroethanol) have been measured at room temperature by Orkin et al.,¹ in 0.5 nm increments over the wavelength range 163–195.5 nm, and Rajakumar et al.² at 184.9 nm. The value of Rajakumar et al. at 184.9 nm is a factor of ~1.8 greater than the corresponding value of Orkin et al. The recommended cross sections given in 1 nm increments in Table 4E-22 for the 163–195 nm range were taken from Orkin et al. after rounding to 3 significant figures. For the range 200–220 nm, the recommended values were obtained from a log-linear fit (185–195 nm) and extrapolation of the Orkin et al. data, $\log \sigma(\lambda) = -1.1939 - 0.09335 \lambda$. An estimated uncertainty factor of 1.15 (2 σ) is recommended for the 163–195 nm wavelength range.

Photolysis Quantum Yield and Product Studies: No recommendation.

E23. CHF₂CH₂OH (2,2-difluoroethanol)[Back to Index](#)

(1)

(New Entry)

Absorption Cross Sections: UV absorption cross sections of CHF₂CH₂OH (2,2-difluoroethanol) have been measured at 295 K by Orkin et al.¹ in 0.5 nm increments over the wavelength range 163–194 nm. The Orkin et al. measurements are the only UV absorption data currently available for this molecule. The recommended cross sections given in 1 nm increments in Table 4E-23 for the 163–194 nm range were taken from this study. For the range 195–220 nm, the recommended values were obtained from a log-linear fit (185–194 nm) and extrapolation of the Orkin et al. data, $\log \sigma(\lambda) = 1.0683 - 0.10785 \lambda$. An estimated uncertainty factor of 1.15 (2 σ) is recommended for the 163–194 nm wavelength range.

Photolysis Quantum Yield and Product Studies: No recommendation.

E24. CF₃CH₂OH (2,2,2-trifluoroethanol)

[Back to Index](#)

(1)

(New Entry)

Absorption Cross Sections: UV absorption cross sections of CF₃CH₂OH (2,2,2-trifluoroethanol) have been measured at room temperature by Orkin et al.¹ in 0.5 nm increments over the wavelength range 163–201 nm and by Salahub and Sandorfy² over the range 119.8–192.3 nm. The cross sections of Salahub and Sandorfy are greater than those of Orkin et al. at all overlapping wavelengths. The discrepancy increases at longer wavelengths, ranging from a 17% difference at 163 nm up to a factor of 6.9 at 192 nm. The Orkin et al. data are considered more reliable at the longer wavelengths, as the Salahub and Sandorfy study was primarily focused on locating absorption features rather than determining absorption cross sections. The recommended cross sections given in 1 nm increments in Table 4E-24 for the 163–201 nm range were taken from Orkin et al. For the range 205–220 nm, the recommended values were obtained from a log-linear fit (191–201 nm) and extrapolation of the Orkin et al. data, $\log \sigma(\lambda) = 4.5910 - 0.12932 \lambda$. Estimated uncertainty factors (2σ) of F(λ) = 1.15 + 4 × 10⁻²³/σ(λ) are recommended for the 163–201 nm wavelength range.

The recommended Lyman-α (121.567 nm) cross section was interpolated from the data of Salahub and Sandorfy² with an estimated uncertainty factor (2σ) of 1.3.

Photolysis Quantum Yield and Product Studies: No recommendation.

E25. CF_3OOCF_3 (hexafluorodimethyl peroxide)

[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of hexafluorodimethyl peroxide, CF_3OOCF_3 , has been measured at room temperature over the wavelength range 200–263 nm by Meller and Moortgat.¹ The continuous spectrum shows part of a broad absorption band with monotonically increasing cross sections with decreasing wavelength. The recommended absorption cross sections in Table 4E-25 are values averaged over 1 nm intervals of the 0.2 nm resolution spectrum from Meller and Moortgat.¹

Photolysis Quantum Yield and Product Studies: No recommendation.

E27. CF₃CHO (trifluoroacetaldehyde)[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of trifluoroacetaldehyde, CF₃CHO, has been measured at room temperature by Lucazeau and Sandorfy⁶ (118–182 and 250–357 nm), Meller et al.⁷ (229–364 nm), Francisco and Williams⁴ (230–400 nm), Sellevåg et al.¹⁰ (200–400 nm), Hashikawa et al.⁵ (200–500 nm), and Chiappero et al.² (230–360 nm). The UV absorption spectrum has an absorption band between 227 and 360 nm with a maximum at 301 nm and weak diffuse structure at wavelengths >250 nm. The absorption cross sections reported by Francisco and Williams,⁴ Meller et al.,⁷ Sellevåg et al.,¹⁰ Hashikawa et al.,⁵ and Chiappero et al.² are in reasonable agreement, generally to within 10% or better, in the wavelength region 245–354 nm. There are larger discrepancies in the long and short wavelength wings of the absorption band. In these regions, the cross sections from Sellevåg et al.¹⁰ are smaller than those from Francisco and Williams⁴ and larger than those from Meller et al.⁷ The data of Lucazeau and Sandorfy,⁶ which are reported in graphical form, are appreciably smaller than those reported in the other studies. The recommended absorption cross sections in Table 4E-27 are taken from Sellevåg et al.¹⁰

The temperature dependence of the absorption spectrum was examined by Chiappero et al.² (230–360 nm) between 249 and 297 K. No discernible variation of the absorption spectrum with temperature was observed. Borkowski and Ausloos¹ (313 and 334 nm) reported absorption cross sections at 329 K that are in agreement with the 298 K recommendation.

Photolysis Quantum Yield and Product Studies: The photolysis quantum yield for CF₃CHO and the product branching ratios are wavelength dependent. Sellevåg et al.¹⁰ determined the effective atmospheric photolysis quantum yield for CF₃CHO using an outdoor photoreactor to be <0.02. Dodd and Watson-Smith³ determined the products following photolysis at 313 nm to be $\Phi_1 = 0.12$ and $\Phi_2 = 0.021$. Pearce and Whytock⁸ reported $\Phi_2 = 0$ for 313 nm photolysis. Richer et al.⁹ studied the products formed following 254 nm photolysis and reported product yields of CHF₃ (14%), CF₂O (80%), CO (65%), CO₂ (45%) and $\Phi_2 = 0.14$. At 366 nm, Richer et al.⁹ observed only a small degree of dissociation after >6 hours of photolysis. Chiappero et al.² reported photolysis quantum yields of $\Phi_1 = 0.41 \pm 0.07$ and $\Phi_2 = 0.38 \pm 0.07$ at 254 nm and $\Phi_1 = 0.17 \pm 0.03$ and $\Phi_2 \sim 0$ at 308 nm. Quantum yields of $\Phi_1 = 0.15 \pm 0.03$ and $\Phi_2 < 0.02$ are recommended at 313 nm.

E28. $CF_3C(O)F$ (trifluoroacetyl fluoride)

[Back to Index](#)

(Recommendation: 06-2, Note: 15-10, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of trifluoroacetyl fluoride, $CF_3C(O)F$, has been measured at room temperature by Meller et al.³ (200–281 nm), Rattigan et al.⁴ (200–295 nm), and Malanca et al.² (200–340 nm). The cross sections from Meller et al.³ and Malanca et al.² are in good agreement in the spectral region 200–260 nm. The position of the absorption maximum near 213 nm reported by Rattigan et al.⁴ is shifted by ~3 nm to longer wavelengths as compared to that reported by Meller et al.³ and Malanca et al.² The cross sections from these studies differ by 20 to 30% at wavelengths >260 nm.

The temperature dependence of the absorption spectrum has been reported by Rattigan et al.⁴ (233–293 K) and Malanca et al.² (238–300 K). For wavelengths >210 nm, the absorption cross section decreases with decreasing temperature. The recommended absorption cross sections in Table 4E-28 are taken from Malanca et al.² in the region 200–260 nm at 300 and 238 K. In the region 265–280 nm, the data of Meller³ are recommended at 297 K and those of Rattigan et al.⁴ at 238 K. An uncertainty factor of 1.2 (2σ) is recommended for the 297 and 300 K cross section data given in Table 4E-28.

Photolysis Quantum Yield and Product Studies: Bierbrauer et al.¹ measured the quantum yield of disappearance of $CF_3C(O)F$ at 240 and 254 nm to be $\Phi_1 + \Phi_2 = 1.02 \pm 0.05$. It is assumed that this applies over the wavelength region 200–300 nm.

Table 4E-28. Recommended Absorption Cross Sections of CF₃C(O)F at 297/300 K and 238 K

λ (nm)	$10^{20} \sigma$ (cm ²) 297 and 300 K	$10^{20} \sigma$ (cm ²) 238 K
200	10.90	10.93

E29. FC(O)C(O)F (oxalyl fluoride)

[Back to Index](#)

(New)

Absorption Cross Sections: UV absorption cross sections of FC(O)C(O)F (oxalyl fluoride) have been measured at room temperature by Balfour¹ (293–309 nm), Cobos et al.² (193, 248 nm), and McGillen et al.³ (190–330 nm). McGillen used two detection methods: a monochromator / photomultiplier tube (PMT) apparatus for wavelengths 190–260 nm and a diode array spectrometer for 210–330 nm; cross sections from both approaches are in good agreement. Relative to McGillen et al., the 248 nm cross section of Cobos et al. agrees within 10%, but the 193 nm value of Cobos et al. is more than 50% larger. The reported values of Balfour were obtained at high resolution and are highly structured, but the general contour agrees with McGillen et al. The recommended cross sections given in Table 4E-29 are from McGillen et al. and are 2 nm values from their data between 190–330 nm (reported every 2 nm for 190–210 nm using their PMT apparatus and every 0.5 nm for 210–330 nm using their diode array spectrometer). An estimated uncertainty factor (2σ) of 1.1 is recommended.

Photolysis Quantum Yield and Product Studies: McGillen et al.³ conducted product studies of FC(O)C(O)F photolysis at 248 nm by reacting the radical products of photolysis with Br₂ to form stable bromides for detection, e.g., FCO radicals from photolysis were efficiently scavenged by Br₂ to form BrC(O)F. The yield for BrC(O)F was found to be greater than ~90%, indicating that the FCO radical is the dominant photolysis product. CF₂O was found to have a primary photolysis yield of ~10%.

E30. FC(O)CF₂C(O)F (difluoromalonyl fluoride)

[Back to Index](#)

(New)

Absorption Cross Sections: UV absorption cross sections of FC(O)CF₂C(O)F (difluoromalonyl fluoride) have been measured at room temperature by McGillen et al.¹ (190–270 nm), the only study available. McGillen used two detection methods: a monochromator/photomultiplier tube apparatus for wavelengths 190–260 nm and a diode array spectrometer for 210–270 nm. Cross sections from both approaches are in good agreement overall (typically to within <10%); however, the diode array spectrometer results usually lie outside the small uncertainty range (0.1–1.8%) with which the PMT results were reported. The recommended cross sections given in Table 4E-30 are from McGillen et al. and are 5 nm values from their data between 190–270 nm (reported every 2 nm for 190–210 nm using their PMT apparatus, every 5 nm for 210–260 nm using their PMT apparatus, and every 0.5 nm for 260–270 nm using their diode array spectrometer). An estimated uncertainty factor (2 σ) of 1.1 is recommended.

Photolysis Quantum Yield and Product Studies: McGillen et al.¹ conducted product studies of FC(O)CF₂C(O)F photolysis at 248 nm by reacting the radical products of photolysis with Br₂ to form stable bromides for detection, e.g., FCO radicals from photolysis were efficiently scavenged by Br₂ to form BrC(O)F. The yield

for BrC(O)F was found to be greater than ~90%, indicating that the FCO radical is the dominant photolysis product.

E31. FC(O)CF₂CF₂C(O)F (tetrafluorosuccinyl fluoride)

[Back to Index](#)

FC(O)CF₂CF₂C(O)F + hν → Products

(New)

Absorption Cross Sections: UV absorption cross sections of FC(O)CF₂CF₂C(O)F (tetrafluorosuccinyl fluoride) have been measured at room temperature by McGillen et al.¹ (190–270 nm), the only study available. McGillen used two detection methods: a monochromator/photomultiplier tube apparatus for wavelengths 190–264 nm and a diode array spectrometer for 210–270 nm. Cross sections from both approaches are in good agreement overall (typically within <10%); however, the diode array spectrometer results usually lie outside the small uncertainty range (0.2–2.5%) with which the PMT results were reported. The recommended cross sections given in Table 4E-31 are from McGillen et al. and are 5 nm values of their data between 190–270 nm (reported every 2 nm for 190–264 nm using their PMT apparatus and every 0.5 nm for 264–270 nm using their diode array spectrometer). An estimated uncertainty factor (2σ) of 1.1 is recommended.

Photolysis Quantum Yield and Product Studies: McGillen et al.¹ conducted product studies of FC(O)CF₂CF₂C(O)F photolysis at 248 nm by reacting the radical products of photolysis with Br₂ to form stable bromides for detection, e.g., FCO radicals from photolysis were efficiently scavenged by Br₂ to form BrC(O)F. The yield for BrC(O)F was found to be greater than ~90%, indicating that the FCO radical is the dominant photolysis product.

Table 4E-31. Recommended Absorption Cross Sections of FC(O)CF₂CF₂C(O)F (tetrafluorosuccinyl fluoride) at 298 K

λ (nm)	$10^{20} \sigma$ (cm ²)	λ (nm)	$10^{20} \sigma$ (cm ²)

E32. CF₃OONO₂ (trifluoromethyl peroxyxynitrate)

[Back to Index](#)

(Recommendation: 15-10, Note: 15-10, Evaluated: 15-10)

Absorption Cross Sections: The UV absorption cross sections of trifluoromethyl peroxyxynitrate, CF₃OONO₂, have been measured at room temperature by Kopitzky et al.¹ (185–340 nm) and over the temperature range 233–300 K by Malanca et al.² (200–340 nm). The UV absorption spectrum over this wavelength range consists of at least two overlapping continuous absorption bands with maxima below 185 nm and near 260 nm. The spectrum exhibits continuously decreasing absorption cross sections over the 185–340 nm wavelength range. The absorption spectra measured at room temperature in these studies are in agreement for wavelengths ≤290 nm, to within 10% or better. At longer wavelengths, significant discrepancies in the reported spectra are evident, which is most likely due to differences in measurement precision and the accuracy of corrections applied to account for the NO₂ impurity absorption. The recommended room temperature cross sections given in Table 4E-32-1 are taken from Kopitzky et al.

Table 4E-32-1. Recommended Absorption Cross Sections of CF₃OONO₂ at 301 K

λ (nm)	$10^{20} \sigma$ (cm ²)	λ (nm)	$10^{20} \sigma$ (cm ²)
185	430	265	8.2
190	370	270	5.8
195	290	275	4.0
200	220	280	2.6
205	150	285	1.7
210	96	290	1.0
215	74	295	0.69
220	54	300	0.45
225	46	305	0.28
230	38	310	0.20
235	32	315	0.13
240	27	320	0.08
245	22	325	0.050
250	18	330	0.037
255	14.3	335	0.024
260	11.1	340	0.014

Note:

Malanca et al.² reported absorption spectra at 300, 294, 273, 253, and 233 K. The measured spectra were corrected for an unspecified contribution from NO₂ and N₂O₄ impurity absorption, which is particularly important at wavelengths >260 nm. A decrease in absorption cross section over the wavelength range 260 to 340 nm with decreasing temperature was reported. The temperature dependence was parameterized using the empirical expression:

$$\log_{10}(\sigma) = B \times T + \log_{10} \sigma_0$$

where σ and σ_0 are the cross sections in cm² molecule⁻¹ at temperatures T and 0 K, respectively. Malanca et al. reported $\sigma(0\text{ K})$ and B parameters at selected wavelengths as given in Table 4E-32-2.

Table 4E-32-2. Recommended CF₃OONO₂ Absorption Spectrum Temperature Dependence

λ (nm)	$10^3 B$ (K ⁻¹)	$10^{20} \sigma_0(0\text{ K})$ (cm ² molecule ⁻¹)
290	6.8	1.2×10^{-2}
295	8.3	2.9×10^{-3}

E33. CF₃C(O)O₂NO₂ (trifluoroperoxyacetyl nitrate)

[Back to Index](#)

(Recommendation: 06-2, Note: 15-10, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of trifluoroperoxyacetyl nitrate (FPAN), CF₃C(O)O₂NO₂, has been measured at room temperature by Libuda and Zabel² (227–305 nm) and Kopitzky et al.¹ (190–295 nm). These studies are in agreement for wavelengths >260 nm, but have systematic differences at shorter wavelengths with the Kopitzky et al. cross sections being lower. Over this wavelength range, the CF₃C(O)O₂NO₂ spectrum is red shifted by ~5 nm from the CH₃C(O)O₂NO₂ spectrum. The recommended absorption cross sections in Table 4E-33 are averages over 5 nm intervals of the 0.6 nm resolution spectrum reported by Libuda and Zabel.² As reported by Libuda and Zabel,² the estimated cross section uncertainties are ~10% for wavelengths <290 nm and 15 to 45% in the region 295–305 nm.

Photolysis Quantum Yield and Product Studies: No recommendation, although excitation in the UV is expected to break the weak O-ONO₂ bond.

E34. CF₃CH₂CHO (3,3,3-trifluoropropionaldehyde)[Back to Index](#)

(Recommendation: 06-2, Note: 15-10, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of 3,3,3-trifluoropropionaldehyde, CF₃CH₂CHO, has been measured at room temperature by Sellevåg et al.³ (200–400 nm), Chiappero et al.² (230–355 nm), and Antiñolo et al. (230–350 nm).¹ The continuous absorption spectrum has weak diffuse band structure between 270 and 343 nm. The reported spectra are in reasonable agreement, with the cross sections from Sellevåg et al. ~6% greater than the values reported by Chiappero et al. and Antiñolo et al. near the peak of the spectrum. The spectrum reported by Antiñolo et al. is blue shifted by ~1 nm relative to the other two studies. The data reported for the wavelength region above 340 nm are in poor agreement. The recommended 298 K absorption cross sections given in Table 4E-34 were taken from Sellevåg et al.³

Chiappero et al.² measured the temperature dependence of the absorption spectrum over the range 249–297 K and reported no discernible variation of cross section with temperature. Antiñolo et al. measured the spectrum over the temperature range 269–323 K and reported a decrease in absorption cross sections with decreasing temperature between 260 and 330 nm. No recommendation is given for the spectrum temperature dependence.

Photolysis Quantum Yield and Product Studies: Sellevåg et al.³ reported the effective atmospheric photolysis quantum yield for CF₃CH₂CHO using an outdoor photoreactor to be <0.02. The quantum yields for channels 1 and 2 were determined by Chiappero et al.² to be $\Phi_1 = 0.38 \pm 0.09$ and $\Phi_2 = 0.36 \pm 0.07$ for 254 nm photolysis and $\Phi_1 = 0.04 \pm 0.01$ and $\Phi_2 \sim 0$ at 308 nm in 700 Torr of N₂ bath gas.

E35. (CF₃)₂CHOH (1,1,1,3,3,3-hexafluoro-2-propanol)[Back to Index](#)

(1)

(New Entry)

Absorption Cross Sections: UV absorption cross sections of (CF₃)₂CHOH (1,1,1,3,3,3-hexafluoro-2-propanol) have been measured at room temperature by Orkin et al.,¹ in 0.5 nm increments over the wavelength range 163–190 nm, and by Salahub and Sandorfy² over the range 121.21–176.99 nm. The cross sections of Salahub and Sandorfy are greater than those of Orkin et al. at all overlapping wavelengths. The discrepancy generally increases at longer wavelengths, ranging from ~20% at 163 nm to ~50% at 177 nm. The Orkin et al. data are considered more reliable, as the Salahub and Sandorfy study was primarily focused on locating absorption features rather than determining absorption cross sections. The recommended cross sections given in 1 nm increments in Table 4E-35 for the 163–190 nm range were taken from Orkin et al. For the range 195–210 nm, the recommended values were obtained from a log-linear fit (180–190 nm) and extrapolation of the Orkin et al. data, $\log \sigma(\lambda) = 2.5762 - 0.12521 \lambda$. Estimated uncertainty factors (2σ) of $F(\lambda) = 1.15 + 7 \times 10^{-23}/\sigma(\lambda)$ are recommended for the 163–190 nm wavelength range.

The recommended Lyman-α (121.567 nm) cross section was interpolated from the data of Salahub and Sandorfy² with an estimated uncertainty factor (2σ) of 1.3.

Photolysis Quantum Yield and Product Studies: No recommendation.

E36. CF₃C(O)OH (trifluoroacetic acid)[Back to Index](#)

(Recommendation: 06-2, Note: 15-10, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of trifluoroacetic acid, CF₃C(O)OH, was measured at room temperature over the wavelength range 200–280 nm by Rattigan et al.,¹ the only study available, using diode array spectroscopy. The spectrum exhibits an absorption band with a broad maximum near 220 nm. The absorption spectrum of CF₃C(O)OH is red shifted from the CH₃C(O)OH spectrum and has lower absorption cross sections. The recommended absorption cross sections in Table 4E-36 are from Rattigan et al.¹

Photolysis Quantum Yield and Product Studies: No recommendation.

E37. CH₃C(O)F (acetyl fluoride)[Back to Index](#)

(Recommendation: 25-1, Note: 25-1, Evaluated: 25-1)

Absorption Cross Sections: The UV absorption spectrum of acetyl fluoride, CH₃C(O)F, has been measured at room temperature by Rattigan et al.¹ (200–310 nm), using diode array spectroscopy, and Song et al.² (201–260 nm) using a scanning spectrometer. There is reasonable agreement between the two studies near the peak of the spectrum, around 206 nm, but significant discrepancies in the long-wavelength limit of the Song et al. spectrum. The Rattigan et al. spectrum shows two absorption bands with a maximum cross section near 206 nm and a shoulder near 260 nm. The recommended absorption cross sections in Table 4E-37 are from Rattigan et al.¹

Photolysis Quantum Yield and Product Studies: Song et al.² have reported a CH₃C(O)F photolysis quantum yield of 0.62 for 248 nm photolysis in 655 mbar total pressure.

E40. CF₂=CF₂ (tetrafluoroethylene)[Back to Index](#)

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The VUV/UV absorption spectrum of tetrafluoroethylene, CF₂=CF₂, has been measured at room temperature by Sharpe et al.³ (185–209 nm), Orkin et al.² (164–220 nm), and Eden et al.¹ (113–330 nm). The spectrum shows a structured absorption band with five maxima between 170 and 200 nm (maximum near 188 nm). The spectra from Orkin et al.² and Eden et al.¹ agree to within 10% in the range 164–182 nm, 20% in the range 182–200 nm, and 10% in the range 203–205 nm. Above 195 nm, the absorption cross sections decrease monotonically toward longer wavelengths. The spectrum reported by Eden et al.¹ deviates from that of Orkin et al.² at wavelengths >200 nm, but the Eden et al. spectrum is very noisy in this region. The absorption spectrum reported by Sharpe et al.³ is systematically shifted by 1 to 2 nm to shorter wavelengths relative to the Orkin et al.² spectrum. The recommended absorption cross sections given in Table 4E-40 are the mean of the data from Orkin et al.² and Eden et al.¹ for the region 164–205 nm and the data from Orkin et al.² in the region 206–220 nm.

Photolysis Quantum Yield and Product Studies: No recommendation.

E41. CF₂=CFCF₃ (hexafluoropropene)

[Back to Index](#)

CF₂=CFCF₃ + hν → Products

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The VUV/UV absorption spectrum of hexafluoropropene, CF₂=CFCF₃, was measured at room temperature by Sharpe et al.³ (185–209 nm), Orkin et al.² (164–222 nm), and Eden et al.¹ (115–330 nm). The spectrum has overlapping absorption bands between 140 and 220 nm with maxima at 155 and 158.5 nm ($\sigma \approx 3 \times 10^{-17}$ cm² molecule⁻¹), 166, and 180 nm. In the wavelength region 164–200 nm, the cross sections from Orkin et al.² and Eden et al.¹ agree to within 15%. In the region 185–200 nm, the cross sections from Orkin et al.,² Eden et al.,¹ and Sharpe et al.³ agree to within 25%. Above 195 nm, the absorption cross sections decrease toward longer wavelengths. The spectrum reported by Eden et al.¹ deviates from that of Orkin et al.² at wavelengths >200 nm, but the Eden et al. spectrum is very noisy in this region. The recommended absorption cross sections given in Table 4E-41 are the mean of the data from Orkin et al.² and Eden et al.¹ for the region 164–199 nm and the data from Orkin et al.² in the region 200–222 nm.

Photolysis Quantum Yield and Product Studies: No recommendation.

E42. NF₃ (nitrogen trifluoride)

[Back to Index](#)

NF₃ + hν → Products

(1)

(Recommendation: 15-10; Note: 15-10; Evaluated: 15-10)

Absorption Cross Sections: The UV absorption spectrum of nitrogen trifluoride, NF₃, has been measured at room temperature by Makeev et al.⁴ (210–240 nm), Molina et al.⁵ (180–250 nm), and Dillon et al.¹ (184–226 nm), and as a function of temperature by Papadimitriou et al.⁶ (184.95–250 nm, 212–296 K). The room temperature spectra reported by Molina et al., Dillon et al., and Papadimitriou et al. are in good agreement over the common wavelength regions. The data from Makeev et al. are significantly greater than the other studies and are not considered in the recommendation. The room temperature spectrum from the Papadimitriou et al. study is given in Table 4E-42-1.

Table 4E-42-1. Recommended Absorption Cross Sections of NF₃ at 296 K

λ (nm)	$10^{20} \sigma$ (cm ²)
184.95	3.44
190	1.16
195	0.393
200	0.132
205	0.0454
210	0.0168
215	0.00698
220	0.00335
225	0.00154
230	0.000801
235	0.000485
240	0.000287
250	0.000111

Note:

184.95–250 nm: Papadimitriou et al.⁶

Papadimitriou et al. measured the spectrum temperature dependence over the range 212–296 K. They observed a systematic decrease in absorption cross section with decreasing temperature at all wavelengths included in their study. The absorption spectrum was parameterized using the empirical formula:

$$\log_{10}(\sigma(\lambda, T)) = \sum_i A_i \lambda^i + (296 - T) \sum_i B_i \lambda^i$$

and the parameters are given in Table 4E-42-2. The parameterization is recommended here. The parameterization reproduces the Molina et al. and Dillon et al. datasets to better than ~10% at all wavelengths. An uncertainty factor of 1.1 (2 σ) for the room temperature absorption spectrum is assigned, which encompasses the range of the available experimental data.

Table 4E-42-2. Recommended NF₃ UV Absorption Spectrum, $\sigma(\lambda, T)$, Parameterization

I	A_i	B_i
0	-218.67	0.9261
1	4.03743	-0.0130187
2	-0.0295605	6.096×10^{-5}
3	9.596×10^{-5}	-9.75×10^{-8}
4	-1.3171×10^{-7}	9.76×10^{-12}
5	4.929×10^{-11}	—

Note:

Papadimitriou et al.⁶

NF₃ VUV absorption cross sections have been measured in the 126.6–178.6 nm wavelength region by La Paglia and Duncan³ and at 147 nm by Inel.² The absorption cross section value reported by Inel is approximately a factor of 2 greater than that reported by La Paglia and Duncan. A recommended Lyman- α cross section of 4.8×10^{-18} cm² molecule⁻¹ was obtained from an extrapolation of the La Paglia and Duncan data. An uncertainty factor of 1.5 (2 σ) is recommended, based primarily on the fact that there are no direct measurements at Lyman- α .

Photolysis Quantum Yield and Product Studies: Dillon et al.¹ measured the F atom quantum yield in the 193 nm photolysis of NF₃ to be 1.03 ± 0.05 . A unit photolysis quantum yield for the loss of NF₃ is recommended over the wavelength range most critical for its atmospheric photolysis, i.e., 190–230 nm.

SECTION 4F. ClO_x PHOTOCHEMISTRY

F1. Cl₂ (molecular chlorine)

[Back to Index](#)

(Recommendation: 25-1, Note: 25-1, Evaluated: 25-1)

Absorption Cross Sections: The recommended absorption cross sections of Cl₂, molecular chlorine, in the range 260–500 nm are taken from the work of Maric et al.,¹¹ who studied the absorption spectrum in the range 200–550 nm using a spectral resolution of 0.2 nm at 298 K. These authors also measured banded features in the range 476–496 nm at 0.04 nm resolution. The absorption cross sections can be calculated in the range 250–550 nm at various temperatures with the expression derived from their study and previous investigations:

$$\sigma = 10^{-20} \alpha^{0.5} \left\{ 27.3 \exp \left(-99.0 \alpha \left(\ln \left(\frac{329.5}{\lambda} \right) \right)^2 \right) + 0.932 \exp \left(-91.5 \alpha \left(\ln \left(\frac{406.5}{\lambda} \right) \right)^2 \right) \right\}$$

where $\alpha = \tanh(402.7/T)$; λ in nm, $250 < \lambda < 550$ nm, and T in K; $300 \text{ K} > T > 195 \text{ K}$. Cross sections calculated at 298 K for 260–500 nm are given in Table 4F-1. Ganske et al.⁸ have also measured the cross sections at room temperature and the agreement with the recommended values is excellent. These two sets of data also agree well with earlier recommendations, which were based on the work of Seery and Britton,¹⁴ which is in turn in good agreement with the results reported by Gibson and Bayliss,⁹ Fergusson et al.,⁷ and Burkholder and Bair.¹ At wavelengths >250 nm, the absorption cross sections measured at room temperature by Hubinger and Nee¹⁰ are in excellent agreement with the values of Maric et al.¹¹ However, in the range 200–250 nm the cross sections deviate considerably between these groups. Room temperature cross sections have also been obtained by Roxlo and Mandl¹³ for the range 170–214 nm. The absorption cross sections reported by Chen and Zhu^{3,4} and Chen et al.⁵ for the 300–420 nm region at 5 and 10 nm intervals deviate by up to ~30% from those reported by Maric et al.¹¹ Room temperature cross sections reported by Tellinghuisen¹⁵ (200–600 nm) agree with the recommended values between 260 and 450 nm. Young et al.¹⁶ have reported cross section data in the 509–570 nm region at 197, 233, 273, and 298 K, where the spectrum consists of weak diffuse bands. The Young et al. and Maric et al. experimental measurements at 298 K are in rough agreement between 509 and 550 nm. The Young et al. 298 K cross section data is recommended and included in Table 4F-1.

Photolysis Quantum Yield and Product Studies: The estimated atmospheric photodissociation rate is only weakly affected by the temperature dependence of the spectrum. Chinin⁶ measured an upper limit of 5% for the branching ratio for excited atomic Cl*(²P_{1/2}) at 351 nm in agreement with earlier studies by Busch et al.² at 347.1 nm and Park et al.¹² at 308 and 340–355 nm, who determined an upper limit for Cl* formation of 0.01.

Table 4F-1. Recommended Absorption Cross Sections of Cl₂ at 298 K

λ (nm)	$10^{20} \sigma$ (cm ²)	λ (nm)	$10^{20} \sigma$ (cm ²)	λ (nm)	$10^{20} \sigma$ (cm ²)

F2. ClO (chlorine monoxide)

[Back to Index](#)

ClO + hν → Cl + O(³ P)	269 kJ mol ⁻¹	445 nm	(1)
→ Cl + O(¹ D)	458 kJ mol ⁻¹	262 nm	(2)

(Recommendation: 06-2, Note: 25-1, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of chlorine monoxide, ClO, shown in Figure 4F-2-1, is partly composed of a continuum absorption band from 210 nm to the maximum near 265 nm, and a characterized banded structure of a strong $A^2\Pi_{3/2} \leftarrow X^2\Pi_{3/2}$ transition, superposing a weak $A^2\Pi_{1/2} \leftarrow X^2\Pi_{1/2}$ system between 265 nm and 315 nm. Watson¹⁶ has reviewed the cross section measurements prior to 1977. The more recent measurements yield results in reasonable agreement with the earlier studies by Mandelman and Nicholls⁹ (250–310 nm), Wine et al.¹⁷ (near 283 nm), Rigaud et al.¹¹ (272–324 nm), Jourdain et al.⁶ (272–320 nm), Barton et al.¹ (274–306 nm) at 315 K, Lang et al.⁷ (253.7 and 257.7 nm), Sander and Friedl¹² (244–317 nm, 275.2 nm) at 220, 298, and 400 K, Troler et al.¹⁵ (220–350 nm, 282.65 nm) over the temperature range 200–263 K, and Simon et al.¹⁴ (240–310 nm). The peak cross section at the maximum of the continuum (near 265 nm) is 5.2×10^{-18} cm² molecule⁻¹, based on the average of the results from Jourdain et al., Sander and Friedl, Troler et al., Simon et al., and Johnston et al.⁵ At 257.7 nm an average value of $(4.86 \pm 0.04) \times 10^{-18}$ cm² molecule⁻¹ was calculated from the data of the Mandelman and Nicholls, Lang et al., Sander and Friedl, Troler et al., and Simon et al. studies. It should be noted that the cross sections in the structured region of the spectrum are extremely dependent on instrument resolution. Figure 4F-2-1 shows a spectrum of ClO based on the data of Sander and Friedl. The recommended absorption cross sections listed in Table 4F-2-1 are averages over 1 nm intervals of the continuous and banded regions of the spectrum measured at a resolution of 0.3 nm by Sander and Friedl. In Table 4F-2-2 the absorption cross sections for the band heads of the $v', v'' = 1, 0$ to 21, 0 transitions measured at various spectral resolutions are compared.

The cross sections of the continuum are independent of temperature (Troler et al.¹⁵), while the structured part of the spectrum is extremely temperature dependent, the bands sharpen and increase in intensity with decreasing temperature. Sander and Friedl¹² measured the temperature dependence at the peak of the 12, 0 band (275.2 nm) over the range 220–400 K and Troler et al.¹⁵ measured the temperature dependence at the peak of the 9, 0 band (282.65 nm) over the range 200–298 K. Clyne and Coxon² determined the following relationship for the 11, 0 sub-band relative to the 294 K value for the temperature range 294–240 K:

$$\sigma_{294} / \sigma_T = 1 + 0.0036 (T - 294)$$

Maric and Burrows¹⁰ performed an analysis of the ClO spectrum and developed an analytical approach that allows the calculation of the UV absorption spectrum as a function of temperature and spectral resolution. Feierabend et al.⁴ measured the ClO differential absorption cross section, i.e., peak to valley, $\Delta\sigma_{\text{ClO}}$, for the 10, 0 band head (~279.6 nm) at 218, 243, 273, and 296 K with a laser bandwidth of 0.005 nm. An empirical temperature dependence parameterization yielded $\Delta\sigma_{\text{ClO}}(T)/\Delta\sigma_{\text{ClO}}(296 \text{ K}) = 3.5234 - 0.014486T + 2.0137 \times 10^{-5} T^2$ (T in units of K).

Photolysis Quantum Yield and Product Studies: The calculations of Coxon et al.³ and Langhoff et al.⁸ indicate that photodecomposition of ClO accounts for at most 2 to 3% of the total destruction rate of ClO in the

stratosphere, which occurs predominantly by reaction with oxygen atoms and nitric oxide. The photodissociation of thermal ClO radicals in the wavelength range $237 < \lambda < 270$ nm was studied by Schmidt et al.¹³ using REMPI. $\text{Cl}(^2\text{P}_{3/2,1/2})$ and $\text{O}(^1\text{D})$ were formed with unity quantum yield. The threshold wavelength for $\text{O}(^1\text{D})$ production was determined to be 263.4 nm. In the structured region of the spectrum oxygen atoms are formed in the triplet ground state.

F3. ClOO (chlorine superoxide)

[Back to Index](#)

(Recommendation: 92-20, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: Johnston et al.² measured the absorption spectrum of the ClOO radical, chlorine superoxide, using a molecular modulation technique and determined absorption cross sections using a complex kinetic scheme interpretation. More recently, Mauldin et al.³ (220–280 nm, 191 K) and Baer et al.¹ (240–300 nm, 300 K) have reported cross section measurements. These two studies are in reasonable agreement with cross section values that are more than twice the earlier Johnston et al.² values. The recommended cross sections in Table 4F-3 are taken from Mauldin et al.³

Photolysis Quantum Yield and Product Studies: The photolysis quantum yield is assumed to be unity over the entire UV absorption band.

Table 4F-3. Absorption Cross Sections of ClOO at 191 K

F4. OCIO (chlorine dioxide)

[Back to Index](#)

OCIO + hv	$\rightarrow \text{O}(^3\text{P}) + \text{ClO}$	251 kJ mol ⁻¹	476 nm	(1)
	$\rightarrow \text{Cl} + \text{O}_2 (^3\Sigma_g^-)$	22 kJ mol ⁻¹	5500 nm	(2)
	$\rightarrow \text{Cl} + \text{O}_2 (^1\Delta_g)$	116 kJ mol ⁻¹	1030 nm	(3)
	$\rightarrow \text{ClOO}$	-10 kJ mol ⁻¹	All	(4)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV/vis absorption spectrum of chlorine dioxide, OCIO, is characterized by a series of well developed progressions of bands extending from ~280 to 480 nm corresponding to the $\text{A} (^2\text{A}_2) (i,j,k) \leftarrow \text{X} (^2\text{B}_1) (0,0,0)$ vibronic transitions. The spectroscopy of this molecule has been studied extensively and the quantum yield for photodissociation appears to be unity throughout the above wavelength range. See for example, the review by Watson.²³ Birks et al.³ have estimated an atmospheric photodissociation half-life of OCIO of a few seconds. The measurement of absorption spectra at temperatures between 200 and 378 K has been the subject of many studies as summarized in Table 4F-4-1.

Table 4F-4-1. Summary OCIO Cross Section Studies

Study	Year	Type	Temperature (K)	Wavelength Range (nm)	Resolution (nm)
Martin and Gareis ¹⁹	1956		298	263–414	Not given
Knauth et al. ¹⁵	1979	A	333	270–440	0.3–1
Wahner et al. ²²	1987	A	204, 296, 378	242–477	0.25
Hubinger and Nee ¹⁴	1994	R	298	240–477	Not given
Frost et al. ¹³	1996	R	200	390–454	0.0015–0.0021
Marston et al. ¹⁸	1998	R	298	275–400	0.05
Kromminga et al. ¹⁶	2003	A	213, 233, 253	312.5–440.5	0.01–0.02
Bogumil et al. ⁶	2003	R	293	290–460	0.25

Type:

A: Absolute cross section determination

R: Relative cross section determination

Absorption cross sections at 10 nm intervals for the region 270–440 nm and at 333 K have been reported by Knauth et al.,¹⁵ and for the 351.5 nm maximum at room temperature by Clyne and Coxon⁷ and Basco and Dogra.¹ The absorption cross sections of Wahner et al.²² obtained at a resolution of 0.25 nm, and at 204, 296, and 378 K have been used by Hubinger and Nee,¹⁴ Frost et al.,¹³ and Marston et al.¹⁸ for the calibration of their relative spectra. The values at the peaks of the main vibrational bands $\text{a}(0)$ to $\text{a}(26)$ (i.e., $\text{A} (^2\text{A}_2) (i,0,0) \leftarrow \text{X} (^2\text{B}_1) (0,0,0)$, $i = 0$ to 26) reported by Wahner et al.²² have been selected as recommended absorption cross sections of OCIO in earlier NASA/JPL evaluations. More recently, Kromminga et al.¹⁶ reported high and medium resolution absorption spectra at five temperatures between 213 and 293 K obtained using Fourier transform spectroscopy, which has the advantage of accurate wavelength calibration. There is a clear wavelength shift (~0.2–0.5 nm) between the spectra of Kromminga et al.¹⁶ and Wahner et al.²² that can't be explained by the shift between measurements in air and in vacuum. The absorption cross sections for the band peaks $\text{a}(3)$ to $\text{a}(26)$ reported by Kromminga et al. are smaller by 5–10% than those reported by Wahner et al.²² A decrease of the temperature causes a sharpening of the vibrational bands and an increase of the peak cross sections as observed between 293 and 213 K by Kromminga et al.¹⁶ and between 378 and 200 K by Wahner et al.²²

The recommended absorption cross sections of OCIO in Table 4F-4-2 are averages over 1 nm intervals of the spectrum measured by Wahner et al.²² (0.25 nm resolution). In Table 4F-4-3 are listed the band peaks at 213, 233, 253, 273, and 293 K recorded in the medium resolution (0.2–0.4 nm) spectra by Kromminga et al.¹⁶ The values for the a(21) to a(16) bands at 293 K are the results of Bogumil et al.,⁶ which were measured at medium resolution (0.24–0.44 nm) with the SCIAMACHY pre-flight satellite instrument and scaled to the absorption cross sections measured by Kromminga et al.¹⁶ In addition, the peak cross sections determined by Wahner et al.²² are listed in Table 4F-4-4. Figure 4F-4-1 shows the spectrum of OCIO at 204 K based on the data of Wahner et al.²²

VUV absorption cross sections have been measured by Basco and Morse,² (148–183 nm), Flesch et al.¹² (50–207 nm), Hubinger and Nee¹⁴ (127–183 nm), and Marston et al.¹⁸ (115–191 nm).

Photolysis Quantum Yield and Product Studies: The photochemistry of OCIO is extremely complex, with several electronic excited states involved in the photodissociation dynamics. Several channels have been observed at wavelengths important in the stratosphere, including O + ClO, Cl + O₂, and isomerization to ClOO. Colussi⁸ measured $\Phi(\text{Cl})$ to be <0.01, and $\Phi(\text{O})=1$ (within experimental error) for photolysis at 308 nm. Vaida et al.²¹ and Rühl et al.²⁰ reported Cl atom production at 362 nm and Bishenden et al.^{4,5} measured $\Phi(\text{Cl})$ to be 0.15 ± 0.10 around the same wavelength. In contrast, Lawrence et al.¹⁷ report $\Phi(\text{Cl})$ in the 359–368 nm region to be $<5 \times 10^{-4}$. This conclusion is supported by photofragment studies of Davis and Lee⁹ between 350 and 475 nm, who report $\Phi(\text{Cl}) < 0.2\%$ in the wavelength range 350–370 nm, rising to a maximum of $3.9 \pm 0.8\%$ near 404 nm. In a later study, Davis and Lee¹⁰ report a substantial yield of O₂(¹ Δ_g) and show that the branching ratio between O + ClO and Cl + O₂ depends on the OCIO(A ²A₂) excited state vibrational mode. Delmdahl et al.¹¹ measured the yield of nascent Cl atoms to be below 3.6% for photolysis in the 365–450 nm range. At $\lambda < 365$ nm, there was a sharp increase of the Cl yield, which was attributed to the photolysis of vibrationally excited ClO ($v \geq 4$).

The recommendation is to use a quantum yield value of unity for the production of O(³P) atoms in the range 270–480 nm. An upper limit for the Cl yield can be set at 0.04 for the wavelength range 365–450 nm. While accurate absorption cross section values are valuable for atmospheric measurements of OCIO abundance, the identity of the photodissociation products is only of minor importance in the context of atmospheric processes.

F5. ClO_3 (chlorine trioxide)

[Back to Index](#)

$\text{ClO}_3 + h\nu \rightarrow \text{Products}$

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The NASA/JPL 83 to NASA/JPL 90 recommendations for the absorption cross sections of the ClO_3 radical, chlorine trioxide, were based on the work of Goodeve and Richardson.² Lopez and Sicre⁵ have, however, since shown that the spectrum reported by Goodeve and Richardson is most likely that of Cl_2O_6 . Thermochemical estimates by Colussi et al.¹ further corroborate this assignment.

Grothe and Willner^{3,4} have reported the UV and IR spectra of ClO_3 trapped in a neon matrix following thermal decomposition of Cl_2O_4 or FOClO_3 . By monitoring the amount of ClO formed as a photolysis product of ClO_3 , they determined the absorption cross sections in the range 250–500 nm. The spectrum has a highly structured absorption band around 320 nm ($\sigma \approx 3 \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1}$) and a second band around 425 nm ($\sigma \approx 2.5 \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1}$) as depicted in the review article of Wayne et al.⁶ A broad absorption spectrum between 280 and 450 nm peaking at ~300 nm ($\sigma \approx 1.8 \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$) was recorded for ClO_3 formed by radiolysis of aqueous solutions of chlorate ions. No recommendation is given for the absorption cross sections of ClO_3 in the gas phase.

Photolysis Quantum Yield and Product Studies: No recommendation.

(Recommendation: 15-10, Note: 15-10, Evaluated: 15-10)

Absorption Cross Sections: The UV/vis absorption spectrum of dichlorine monoxide, Cl₂O, has been measured at room temperature by Goodeve and Wallace⁴ (230–620 nm), Finkelnburg et al.³ (220–650 nm), Martin and Gareis⁸ (234–331 nm), Lin⁷ (180–640 nm), Molina and Molina⁹ (200–450 nm), Simon et al.¹⁷ (236–320 nm), Smith et al.¹⁸ (190–399 nm), and Papanastasiou et al.¹⁵ (200–500 nm). The earlier data reported by Goodeve and Wallace,⁴ Finkelnburg et al.,³ and Martin and Gareis⁸ deviate substantially from the more recent results and are not considered further in this evaluation. The spectrum measured by Simon et al.¹⁷ was normalized to the data of Lin.⁷ The spectrum measured by Papanastasiou et al. was scaled to a cross section value of 1.96×10^{-18} cm² molecule⁻¹ at 255 nm. The spectrum exhibits three absorption bands in the UV/vis region. An asymmetrical band between ~220–380 nm with the maximum near 255 nm and a shoulder near 290 nm, and two weak bands at ~380–500 nm and ~500–650 nm with maxima near 420 nm and 550 nm, respectively. The absorption cross sections measured by Lin et al.,⁷ Molina and Molina,⁹ Knauth et al.,⁶ Smith et al.,¹⁸ and Papanastasiou et al. are in very good agreement, i.e., to within 10%, for the UV absorption band between 200 and ~350 nm. The values reported by Molina and Molina⁹ and Knauth et al.⁶ are somewhat larger than those reported by Lin,⁷ which are larger than those reported by Smith et al.¹⁸ The discrepancies between the various data sets are larger in the region of the absorption minimum.

The recommended absorption cross sections listed in Table 4F-6 are from Papanastasiou et al. in the region 200–500 nm, which are in good agreement with the Lin cross section data, and the data from Lin⁷ in the region 510–640 nm. An uncertainty factor of 1.1 (2σ) is estimated for the 200–500 nm wavelength range. The estimated uncertainty encompasses the majority of the available experimental data.

Measurements at 298 and 333 K have been carried out by Knauth et al.⁶ (200–500 nm). Johnsson et al.⁵ (210–350 nm) measured the absorption spectrum in Ar matrices and reported a gas-phase absorption cross section at 260 nm. Papanastasiou et al.¹⁵ reported spectra over the temperature range 201–296 K. They parameterized the Cl₂O spectrum temperature dependence as the sum of six Gaussian functions (polynomial fits were also provided). Their parameterization is recommended and the fit expressions and coefficients can be obtained from their paper.

VUV absorption cross sections have been measured by Nee¹² (150–200 nm) and Motte-Tollet et al.¹¹ (128–190 nm).

Photolysis Quantum Yield and Product Studies: Sander and Friedl¹⁶ have measured the quantum yield for production of O atoms to be 0.25 ± 0.05 , using a broadband photolysis source extending from 180 nm to beyond 400 nm. The main photolysis products are Cl and ClO. Using a molecular beam technique, Nelson et al.¹³ found Cl + ClO to be the only primary photodissociation channel at 308 nm, a major channel at 248 nm, and a minor channel at 193 nm. At 248 nm a fraction of the photoproduct ClO underwent spontaneous photodissociation. These authors found evidence that the dissociation to three atoms 2 Cl + O takes place at 193 nm and that some O(¹D) atoms are generated as well. Papanastasiou et al.¹⁵ measured a O(³P) + O(¹D) quantum yield of 0.85 ± 0.15 following 193 nm photolysis of Cl₂O and a O(³P) quantum yield of 0.20 ± 0.03 for 248 nm photolysis. An analysis presented in Papanastasiou et al. of the Feierabend et al.² measured ClO radical yield and its temporal profile following the 248 nm photolysis of Cl₂O yielded a ClO yield of 0.8, a Cl atom yield of 1.2 ± 0.1 , a O + 2Cl channel yield of 0.2, and a O + Cl₂ channel yield of <0.05. Zou et al.²⁰ studied the 193 and 248 nm photolysis of Cl₂O using photofragment translational spectroscopy. They report a O(³P) quantum yield of 0.15 for 248 nm photolysis and that the O + 2Cl channel is a major product at 193 nm.

Nickolaissen et al.¹⁴ reported that broadband photolysis at wavelengths >300 nm results in pressure-dependent ClO quantum yields, which was explained by the rapid intersystem crossing between two metastable states. These states undergo competitive dissociation to ClO + Cl and collisional relaxation to the ground state. Furthermore, these authors detected a transient absorption spectrum, which was assigned to a long-lived metastable triplet state of Cl₂O. However, Moore et al.¹⁰ estimated the lifetime of the metastable excited state to be much shorter. Chichinin¹ and Tanaka et al.¹⁹ found evidence of ground state (²P_{3/2}) and spin-orbit excited

($^2P_{1/2}$) atomic chlorine photoproducts. The implication is that the photodecomposition quantum yield is less than unity at atmospherically relevant wavelengths in spite of the continuous nature of the absorption spectrum.

F7. ClOOCl (chlorine peroxide, dichlorine dioxide)

[Back to Index](#)

(Recommendation: 15-10, Note: 15-10, Evaluated: 15-10)

Absorption Cross Sections: The gas-phase UV absorption spectrum of ClOOCl is continuous with a maximum near 245 nm, a minimum near 218 nm, and a weak diffuse shoulder in the wavelength region 280–300 nm. There are a number of studies that have reported UV absorption data for ClOOCl over a range of wavelengths or at specific wavelengths. Table 4F-7-1 summarizes the currently available studies. The ClOOCl UV absorption spectra reported by Basco and Hunt¹ and Molina and Molina¹⁸ have been shown to contain systematic errors and are not considered further in this evaluation. In laboratory studies, ClOOCl has been produced in the gas-phase at low temperature as a product of the termolecular ClO radical self-reaction, ClO + ClO + M. Studies, to date, indicate that only one stable isomer of Cl₂O₂ is produced in the ClO self-reaction and that this species is chlorine peroxide, ClOOCl, rather than ClOClO or ClClO₂. Using sub-millimeter wave spectroscopy, Birk et al.² have further established the structure of the reaction product to be ClOOCl. This is in general agreement with the quantum mechanical calculations of McGrath et al.,^{15,16} Jensen and Odersheide,¹⁰ and Stanton et al.,²⁷ although the theoretical study by Matus et al.¹⁴ found the ClClO₂ isomer to be more stable than ClOOCl by 3.1 kcal mol⁻¹ at 298 K.

Cox and Hayman,⁶ Burkholder et al.,⁴ DeMore and Tschuikow-Roux,⁷ Bloss et al.,³ and Papanastasiou et al.²¹ report absolute ClOOCl cross section, $\sigma(\lambda)$, values over a substantial range of wavelengths. The studies of Permien et al.,²² Vogt and Schindler,³⁰ Huder and DeMore,⁹ McKeachie et al.,¹⁷ and Pope et al.²⁵ report absorption spectra normalized to 245 nm. von Hobe et al.³¹ report a solid-phase ClOOCl UV absorption spectrum measured in a Ne matrix at ~10 K with reported cross sections obtained by normalization using the 245 nm cross section recommended in NASA/JPL 06-2²⁶ for the gas-phase spectrum.

Discrepancies in the wavelength dependence of the ClOOCl absorption spectrum at wavelengths >300 nm, the region that is most critical for atmospheric photolysis rate calculations, exist and most likely originate from uncertainties in corrections for spectral interferences by reactant precursors (O₃, Cl₂O, and Cl₂) and impurities (OCIO, Cl₂, and Cl₂O₃) formed in the ClOOCl source chemistry. Near the peak, the reported spectra are in reasonable agreement. The studies of Cox and Hayman, Burkholder et al., DeMore and Tschuikow-Roux, Vogt and Schindler, and McKeachie et al. show systematic deviations that are possibly consistent with spectral interference due to minor absorption by Cl₂O and, in the cases of Cox and Hayman, Burkholder et al., and McKeachie et al., possibly Cl₂O₃. At λ >300 nm, the ClOOCl spectrum is weaker and more sensitive to spectral interferences from impurities, in particular Cl₂. The studies of Burkholder et al. and DeMore and Tschuikow-Roux are the only pre-2007 gas-phase studies that report cross section data at λ >360 nm. Pope et al. developed a method to isolate bulk samples of ClOOCl in which ClOOCl is produced in the gas-phase and condensed at low temperatures. Pope et al. measured gas-phase UV spectra that are due mostly to Cl₂ and ClOOCl absorption following the warming of the condensate. The spectra were analyzed using a Gaussian fitting procedure and

they report a ClOOCl absorption spectrum that decreases rapidly at $\lambda > 320$ nm with a cross section at 350 nm that is a factor of 6 lower than recommended in NASA/JPL 2006. The von Hobe et al. matrix study used the Pope et al. method to prepare their ClOOCl samples and Raman spectroscopy to evaluate the spectral contribution from Cl₂ impurities. They report a ClOOCl spectrum with significant absorption at wavelengths out to 400 nm. von Hobe et al. suggest that Pope et al. mistakenly attributed a long-wavelength ClOOCl spectral feature to Cl₂ impurity.

The study of Papanastasiou et al.,²¹ which is in generally good agreement with the earlier studies, was carried out using diode array spectroscopy and laser photolysis to generate ClO radicals. The spectral analysis utilized reaction stoichiometry and three observed isosbestic points to account for chemical species, including Cl₂, which appear to represent an interference to a greater or lesser degree in all pre-2009 studies. The isosbestic point observed at 408.5 nm shows that ClOOCl absorbs measurably at wavelengths longer than 350 nm.

The study of Young et al.,³³ which was normalized to the cross section measured by Papanastasiou et al. at 245 nm, is in essentially perfect agreement with the latter from 200 nm to 310 nm and diverges from it somewhat at longer wavelengths. Young et al. prepared and purified ClOOCl using the methods described by Pope et al.²⁵ and extended the wavelength range into the visible, where their stated errors are relatively small. Young et al. corrected for Cl₂ absorption by using its structured visible absorption spectrum, which they recently reported.³⁴

Lower limits to the absolute cross sections have been measured recently at specific wavelengths by a new experimental method involving pulsed laser photolysis of ClOOCl in a molecular beam combined with mass spectrometric detection to determine $\sigma(\lambda)\Phi(\lambda)$, where $\Phi(\lambda)$ is the ClOOCl photolysis quantum yield (see Chen et al.⁵). This new method is not sensitive to spectral interference from Cl₂. It yields the lower-limit for the ClOOCl cross sections, assuming $\Phi(\lambda) = 1$, which is thought to be a good assumption. Measurements by Chen et al.⁵, Lien et al.,¹³ and Jin et al.¹¹ are slightly higher than, but in good agreement with, the data of Papanastasiou et al.²¹ Measurements over limited temperature ranges indicate that the cross sections are only weakly dependent on temperature.

Wilmouth et al.³² used flow-tube and atomic resonance fluorescence techniques to measure Cl-atom production when ClOOCl is photolyzed at 248, 308, and 352 nm. By scaling their signals to the known Cl-atom yield in the photolysis of Cl₂ or the literature cross section at the peak of the ClOOCl absorption spectrum, they obtained the product of the ClOOCl absorption cross section and the quantum yield for the Cl-atom production channel, $\sigma(\lambda)\varphi_{\text{Cl}}(\lambda)$, at the three wavelengths. It is noteworthy that the Cl₂ concentration was monitored in situ using fluorescence excited by the resonance lamp, and appropriate corrections to the Cl-atom yields were made. By assuming $\varphi_{\text{Cl}}(\lambda) = 1$, they obtain the lower limit to the absorption cross section. Analyzed in this way, their lower limit cross sections at the three wavelengths are a little lower than the cross sections reported by Papanastasiou et al.,²¹ although the agreement is better when quantum yields (see below) are considered.

The recommended ClOOCl absorption cross sections are based on the measurements of Papanastasiou et al.²¹ (which were corrected on the basis of the isosbestic analysis), Wilmouth et al.³² (which were corrected on the basis of in situ monitoring of Cl₂), and Chen et al.,⁵ Lien et al.,¹³ and Jin et al.¹¹ (which are not susceptible to interfering species), and Young et al.³⁴ (which were normalized to the 245 nm value of Papanastasiou et al.²¹). The data of Papanastasiou et al.²¹ and Wilmouth et al.³² tend to be a little higher than the previous measurements, but somewhat lower than the measurements of Chen et al.,⁵ Lien et al.,¹³ and Jin et al.¹¹ Bloss et al.³ measured a value for $\sigma(210 \text{ nm})$ in a pulsed photolysis ClO + ClO + M kinetics study over the temperature range 183–245 K that is similar to the current recommendation. The recommended values (taken from Papanastasiou et al.²¹ for 200–310 nm and Young et al.³³ for 510–535 nm) for the temperature range 190–250 K are listed in Table 4F-7-2. Near 310 nm, the measurements of Papanastasiou et al. (including an isosbestic point), Wilmouth et al., Chen et al., and Young et al. are in very good agreement; for $\lambda > 310$ nm, the data of Young et al. begins to diverge from the others and the relative errors grow larger. A log-linear interpolation from 310 to 510 nm gives a good representation of all of the data, including the isosbestic point at 408.5 nm. Data at $310 < \lambda < 510$ nm can be estimated from the formula $\sigma(\lambda) = 4.05 \times 10^{-19} \times \exp[-0.0357 \times (\lambda - 310)]$, where λ is in nm and σ is in units of $\text{cm}^2 \text{ molecule}^{-1}$.

Cross Section Uncertainties: The estimated uncertainty factor is 1.35 over the entire wavelength range from 200 to 535 nm.

Photolysis Quantum Yields and Product Studies: Molina et al.¹⁹ reported a quantum yield, Φ , of approximately unity (1.03 ± 0.12) for the Cl + ClOO pathway from a flash photolysis study at 308 nm, in which the yield of Cl atoms was measured using time-resolved atomic resonance fluorescence. These results are in agreement with the steady-state photolysis study of Cox and Hayman.⁶ Plenge et al.²⁴ measured the primary products from

CIOOCl photolysis at 250 and 308 nm using photoionization mass spectrometry. At both wavelengths $2\text{Cl} + \text{O}_2$ was observed as the exclusive product channel corresponding to a primary Cl quantum yield near unity at 250 nm ($\Phi_{\text{Cl}} \geq 0.98$) and at 308 nm ($\Phi_{\text{Cl}} \geq 0.90$). At both photolysis wavelengths the pathway leading to ClO was not observed corresponding to $\Phi_{\text{ClO}} \leq 0.02$ at 250 nm and $\Phi_{\text{ClO}} \leq 0.10$ at 308 nm.

In a molecular beam/flash-photolysis study Moore et al.²⁰ used photofragment translational spectroscopy to measure the relative Cl:ClO product yields from which they derived branching ratios for both photolysis channels $\text{ClOO} + \text{Cl}$ and $\text{ClO} + \text{ClO}$. At 248 nm, they obtained 0.88 ± 0.07 and 0.12 ± 0.07 respectively, and at 308 nm, 0.90 ± 0.1 and 0.10 ± 0.01 . Huang et al.⁸ also used photofragment translational spectroscopy to re-measure the branching ratios reported by Moore et al. The new results confirm and extend those of Moore et al. Huang et al. identified three product channels: (a) $2\text{Cl} + \text{O}_2$, (b) 2ClO , and (c) $\text{ClO} + \text{Cl} + \text{O}$. The branching ratios among these product channels are 0.82, 0.08, and 0.10 at 248.4 nm, and 0.81, 0.19, and 0.00 at 308.4 nm. These results suggest that the branching ratio of channel-a is only weakly dependent on λ and that of channel-c arises from fragmentation of highly excited ClO radicals; at longer wavelengths, there is not enough available energy to break the bond.

Recommendations: Quantum yield of channel-a $\Phi_a = 0.8 (\pm 0.1)$ at all λ ; $\Phi_b + \Phi_c = 0.2 (\pm 0.1)$ at all λ ; $\Phi_c = 0.0 (\pm 0.1)$ at $\lambda > 300$ nm. Additional determinations of photolysis quantum yields and product branching ratios at wavelengths longer than 300 nm would be desirable.

Theoretical Studies: Toniolo et al.,²⁹ Peterson and Francisco,²³ and Matus et al.¹⁴ report theoretical calculations for the electronic transitions of the CIOOCl UV absorption spectrum that include transitions to excited singlet and triplet states. Peterson and Francisco report that the strongest triplet transition is dissociative to $\text{Cl} + \text{ClOO}$, centered near 385 nm, and is three orders of magnitude weaker than the strongest singlet transition at shorter wavelengths. Kaledin and Morokuma¹² studied the CIOOCl photodissociation dynamics and predict the synchronous and sequential formation of $2\text{Cl} + \text{O}_2$ at 308 nm, and three possible fragmentation routes at 248 nm: $2\text{Cl} + \text{O}_2$, $\text{Cl} + \text{O}(^3\text{P}) + \text{ClO}$, and $2\text{Cl} + 2\text{O}(^3\text{P})$. Similar theoretical calculations performed by Toniolo et al.²⁸ for excitation at 264, 325, and 406 nm found that $2\text{Cl} + \text{O}_2$ was produced at all wavelengths with only a small yield of 2ClO at the shortest wavelength.

F8. ClClO₂ (chloryl chloride)

[Back to Index](#)

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of chloryl chloride, ClClO₂, has been measured in the gas-phase at room temperature and in a noble gas matrix at low temperature by Müller and Willner² (220–390 nm). In another study from the same group, Jacobs et al.¹ (180–390 nm) re-investigated the spectrum. The spectrum has two overlapping absorption bands with maxima at 226 nm ($\sigma = 1.38 \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$) and 296 nm ($\sigma = 1.51 \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$). The recommended absorption cross sections in Table 4F-8 are taken from Müller and Willner.²

Photolysis Quantum Yield and Product Studies: Photolysis of matrix isolated ClClO₂ suggests that it absorbs in the visible between 500 and 800 nm with cross sections estimated to be $<10^{-20} \text{ cm}^2 \text{ molecule}^{-1}$.

Table 4F-8. Recommended Absorption Cross Sections of ClClO₂ at 298 K

λ (nm)	$10^{20} \sigma$ (cm ²)	λ (nm)	$10^{20} \sigma$ (cm ²)	λ (nm)	$10^{20} \sigma$ (cm ²)	λ (nm)	$10^{20} \sigma$ (cm ²)

F9. Cl₂O₃ (dichlorine trioxide, chlorine chlorate)

[Back to Index](#)

(1)

(Recommendation: 06-2, Note: 15-10, Evaluated: 15-10)

Absorption Cross Sections: The UV absorption spectrum of Cl₂O₃ (dichlorine trioxide, chlorine sesquioxide, chlorine chlorate) has been measured by Lipscomb et al.⁵ (257.7 nm) at 293 K, Hayman and Cox⁴ (220–335 nm) at 233 K, Burkholder et al.¹ (220–320 nm) in the range 200–260 K, Harwood et al.³ (220–330 nm) at 223 K, and Green et al.² (201–320 nm) at 243 K. The spectrum has a strong band centered near 265 nm and evidence for another band at shorter wavelengths. Overall, the agreement among the various studies in terms of the absolute absorption cross sections and the wavelength dependence of the spectrum is poor. Hayman and Cox³ report the largest peak absorption cross section and Green et al.² report the lowest, ~30% lower. The spectra from Green et al.² and Burkholder et al.¹ are in reasonable agreement and have significantly lower cross sections in the long wavelength region than reported by Harwood et al.³ and Hayman and Cox.⁴ The recommended absorption cross sections in Table 4F-9 were obtained by averaging the cross section data from Hayman and Cox,⁴ Burkholder et al.,¹ Harwood et al.,³ and Green et al.² Uncertainty factors of 1.5 (2 σ) for $\lambda < 300 \text{ nm}$ and 2 (2 σ) for $\lambda > 300 \text{ nm}$ are estimated due primarily to the large spread in the available cross section studies.

Photolysis Quantum Yield and Product Studies: Absorption in the UV is expected to lead to unit photodissociation.

Table 4F-9. Recommended Absorption Cross Sections of Cl₂O₃ at 220–260 K

λ (nm)	$10^{20} \sigma$ (cm ²)	λ (nm)	$10^{20} \sigma$ (cm ²)	λ (nm)	$10^{20} \sigma$ (cm ²)

F10. Cl₂O₄ (dichlorine tetraoxide, chlorine perchlorate)

[Back to Index](#)

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of Cl₂O₄ (dichlorine tetraoxide, chlorine perchlorate) has been measured at room temperature by Lopez and Sircé² (200–310 nm) and Green et al.¹ (200–350 nm). The absorption spectrum has a weak band between 303 and 350 nm with a maximum at 327 nm, a stronger band between 212 and 303 nm with a maximum at 233 nm, and a further increase in cross section below 212 nm. The absorption cross sections reported by Lopez and Sircé² and Green et al.,¹ who applied similar methods of preparing Cl₂O₄, are in good agreement in the region ~215–250 nm. Discrepancies in the cross section data are apparent below 215 nm, where the values of Lopez and Sircé² are larger by as much as a factor ~1.7 at 200 nm and at wavelengths >260 nm. The recommended absorption cross sections in Table 4F-10 are from Green et al.,¹ which is thought to be the more accurate measurement.

Photolysis Quantum Yield and Product Studies: No recommendation.

F11. Cl₂O₆ (dichlorine hexoxide)[Back to Index](#)

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV/vis absorption spectrum of dichlorine hexoxide, Cl₂O₆, has been measured at room temperature by Lopez and Sicre⁴ (200–386 nm), Jansen et al.³ (268 nm), and Green et al.² (200–450 nm). The spectrum reported by Goodeve and Richardson¹ and attributed to ClO₃ was shown by Lopez and Sicre⁴ to most likely be that of Cl₂O₆. The cross sections measured by Lopez and Sicre⁴ are several times larger than those reported by Goodeve and Richardson¹ but the shape of the spectrum is similar. There is excellent agreement between the data of Lopez and Sicre⁴ and Green et al.² at wavelengths between 210 and 310 nm. At 200 nm the data from Green et al.² are smaller by ~10% than those of Lopez and Sicre.⁴ At longer wavelengths the Green et al.² cross section data are larger with the difference increasing with increasing wavelength up to a factor ~3 at 380 nm. The recommended absorption cross sections in Table 4F-11 are taken from Green et al.²

Photolysis Quantum Yield and Product Studies: No recommendation.

F12. Cl₂O₇ (dichlorine heptoxide)[Back to Index](#)

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of dichlorine heptoxide, Cl₂O₇, has been measured at room temperature by Goodeve and Windsor¹ (222–302 nm) and Lin² (180–310 nm). Although both studies report a spectrum with monotonically decreasing absorption cross sections with increasing wavelength, there is poor agreement between the two data sets. The cross sections reported by Goodeve and Windsor¹ are larger at wavelengths <290 nm than those reported by Lin² with a difference of a factor of 4 at 225 nm. At wavelengths >290 nm, the cross sections reported by Goodeve and Windsor¹ are smaller than those of Lin.² The recommended absorption cross sections in Table 4F-12 are taken from Lin.²

Photolysis Quantum Yield and Product Studies: No recommendation.

F13. HCl (hydrogen chloride)[Back to Index](#)

(Recommendation: 06-2, Note: 15-10, Evaluated: 15-10)

Absorption Cross Sections: The VUV/UV absorption spectrum of hydrogen chloride, HCl, has been measured at room temperature by Romand and Vodar¹⁸ (139–207 nm), Romand¹⁷ (139–207 nm), Myer and Samson¹³ (140–200 nm), Inn⁶ (140–220 nm), Roxlo and Mandl¹⁹ (170–215 nm), Nee et al.¹⁴ (132–185 nm), Bahou et al.² (120–230 nm), Cheng et al.³ (120–230 nm), Vatsa and Volpp²¹ (121.6 nm), Mo et al.¹² (193 nm), and Hanf et al.⁵ (135 nm). Bahou et al.² (120–230 nm) and Cheng et al.³ (120–230 nm) have also measured the absorption spectrum of DCl. VUV absorption cross sections have been obtained by dipole (e,e) spectroscopy in the region 8-40 eV (155–31 nm) by Daviel et al.⁴ The absorption spectrum has a broad absorption band between 135 and 230 nm, corresponding to the A ¹Π ← X ¹Σ⁺ transition, with the maximum at ~154 nm for HCl and ~156 nm for DCl. There is good agreement among the data of Bahou et al.,² Cheng et al.,³ with the data from Nee et al.¹⁴ and Inn.⁶ The cross sections of Bahou et al.² and Cheng et al.³ are in general larger than those of Nee et al.¹⁴ by <10% in the region 132–170 nm and by <25% at wavelengths >170 nm. In addition, the cross sections of Bahou et al.² and Cheng et al.³ are slightly smaller, by <10%, than those of Inn⁶ except for the region >210 nm. The absorption spectrum of Inn⁶ has shoulders near 147.5 nm and 160 nm around the maximum at ~155 nm. This is in contrast to the results of Bahou et al.² and Cheng et al.³ (0.1 nm resolution) and those of Nee et al.¹⁴ (0.05 nm resolution). The recommended absorption cross sections for HCl and DCl in Table 4F-13 are averages over 2.5 nm and 5 nm intervals of the data from Bahou et al.² An uncertainty factor of 1.1 (2σ) is estimated for 180 < λ < 230 nm.

Photolysis Quantum Yield and Product Studies: Photodissociation of HCl was studied by Matsumi et al.⁹⁻¹¹ and Tonokura et al.,²⁰ and the branching fraction Cl (²P_{1/2}) / (Cl (²P_{1/2}) + Cl (²P_{3/2})) was determined to be 0.33 ± 0.05 at 193 nm and 0.45-0.47 (± 0.04) at 157 nm. Lambert et al.⁷ measured branching fractions between 0.47 and 0.33 for eight wavelengths between 193 and 235 nm for HCl. Zhang et al.²² obtained 0.41 ± 0.01 at 193.3 nm. Regan et al.¹⁶ obtained values between 0.42 and 0.48 for 5 wavelengths in the range 201–210 nm, and Regan et al.¹⁵ report values between 0.41 to 0.53 for selected ro-vibrational states at 235 nm. The results from Lambert et al.,⁷ Zhang et al.,²² Regan et al.,^{15,16} and Liyanage et al.⁸ are in good agreement with the calculations of Alexander et al.¹

F14. HOCl (hypochlorous acid)

[Back to Index](#)

(Recommendation: 06-2, Note: 15-10, Evaluated: 15-10)

Absorption Cross Sections: The UV/vis absorption spectrum of hypochlorous acid, HOCl, has an intensive singlet-singlet absorption in the near-UV with a maximum near 240 nm due mostly to the $2\ ^1A' \leftarrow 1\ ^1A'$ transition and a weaker band arising from the $1\ ^1A'' \leftarrow 1\ ^1A'$ transition that appears as a shoulder near 300 nm. The absorption cross sections of HOCl vapor have been reported by several groups. Molina and Molina¹⁰ and Knauth et al.⁷ produced HOCl using equilibrium mixtures with Cl₂O and H₂O. Mishalanie et al.⁹ and Permien et al.¹² used a dynamic source to generate the HOCl vapor. The cross section values reported by Molina and Molina,¹⁰ Mishalanie et al.,⁹ and Permien et al.¹² are in reasonable agreement between 250 and 330 nm. In this wavelength range, the cross section values reported by Knauth et al.⁷ are significantly smaller, e.g. a factor of 4 at 280 nm. At wavelengths >340 nm, the cross sections from Mishalanie et al. are significantly smaller than those obtained by the other three groups with a difference of an order of magnitude at 365 nm.

Burkholder³ (200–380 nm) measured the HOCl absorption spectrum following photolysis of equilibrium mixtures of Cl₂O–H₂O–HOCl. The HOCl spectrum obtained has two absorption maxima with peaks at 242 and 304 nm in excellent agreement with the work of Knauth et al.⁷ The agreement with the spectra reported by Molina and Molina,¹⁰ Mishalanie et al.,⁹ and Permien et al.¹² is poor. The discrepancies can most likely be attributed to the methods and uncertainties associated with correcting measured absorption spectra for the presence of Cl₂ and Cl₂O. In the study by Burkholder,³ several control experiments were carried out in order to check the internal consistency of the data. Barnes et al.¹ examined the near UV HOCl spectrum by monitoring the OH fragments resulting from photodissociation and observed a weak band centered at 387 nm that extends to 480 nm. This transition arises from a weak singlet-triplet transition (Minaev⁸). The recommended cross sections in Table 4F-14 are calculated from an analytical expression provided by Barnes et al.¹ that was based on the cross section values from Burkholder³ and Barnes et al.¹ The HOCl spectrum reported by Jungkamp et al.⁶ is in excellent agreement with this recommendation for wavelengths <350 nm but deviates significantly at longer wavelengths. Uncertainty factors of 1.1 (2 σ) and 1.2 (2 σ) are estimated for the wavelength regions $\lambda \leq 350$ nm and $\lambda > 350$ nm, respectively.

Photolysis Quantum Yield and Product Studies: Molina et al.¹¹ observed production of OH radicals in the laser photolysis of HOCl around 310 nm. Butler and Phillips⁴ found no evidence for O atom production following HOCl photolysis at 308 nm and reported an upper limit for the primary quantum yield for the HCl + O channel of ~0.02. Vogt and Schindler¹⁴ used broadband photolysis in the 290–390 nm wavelength range and report $\Phi(\text{OH})$ to be >0.95. Schindler et al.¹³ measured $\Phi(\text{Cl})$ to be 1.00 ± 0.05 at 308 nm. These authors also determined the probability, P, for production of Cl*(²P_{1/2}) relative to Cl(²P_{3/2}) to be 0.035 ± 0.02 at 308 nm, and 0.35 ± 0.02 at 235 nm. These values are in agreement with the value of 0.30 ± 0.07 at 236 nm reported by

Bell et al.² Fujiwara and Ishiwata⁵ determined the relative yield of OH(²Π_{3/2}) / OH(²Π_{1/2}) to be 2.0 at 266 nm and 1.5 at 355 nm. A unit quantum yield for the OH + Cl channel is recommended.

Table 4F-14. Recommended Absorption Cross Sections of HOCl at 298 K

F15. ClNO (nitrosyl chloride)

[Back to Index](#)

(Recommendation: 02-25, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: Nitrosyl chloride, ClNO, has a continuous UV/vis absorption spectrum extending beyond 650 nm. There is good agreement between the work of Martin and Gareis⁶ (235–400 nm), Ballash and Armstrong¹ (185–540 nm), Illies and Takacs⁵ (190–400 nm), and Tyndall et al.⁹ (190–350 nm) except around 230 nm where the values of Ballash and Armstrong are larger by almost a factor of two. Roehl et al.⁷ (350–650 nm) measured ClNO absorption cross sections at several temperatures between 223 and 343 K. Their room temperature results agree to within 15% with those of Martin and Gareis,⁶ Ballash and Armstrong,¹ and Tyndall et al.⁹ The recommended absorption cross sections in Table 4F-15 are taken from the work of Tyndall et al.⁹ between 190 and 350 nm and from Roehl et al.⁷ beyond 350 nm.

Photolysis Quantum Yield and Product Studies: The quantum yield for the primary photolytic process has been reviewed by Calvert and Pitts.² The quantum yield is unity over the entire visible and near-ultraviolet bands. Chichin³ found evidence of ground state (²P_{3/2}) and excited (²P_{1/2}) atomic chlorine products and measured a relative quantum yield Cl(²P_{1/2})/ (Cl(²P_{1/2}) + Cl(²P_{3/2})) to be 0.88 ± 0.12 at 248 nm and 0.90 ± 0.10 at 351 nm. Felder and Morley⁴ obtained 0.80 at 248 nm and Skorokhodov et al.⁸ obtained 0.48 ± 0.03 at 212 nm, 0.30 at 235 nm, and 0.52 ± 0.03 at 248 nm.

Table 4F-15. Recommended Absorption Cross Sections of ClNO at 298 K

F16. ClNO₂ (nitryl chloride)[Back to Index](#)

(Recommendation: 15-10, Note: 15-10, Evaluated: 15-10)

Absorption Cross Sections: The UV absorption spectrum of nitryl chloride, ClNO₂, has been measured at room temperature by Martin and Gareis⁶ (230–330 nm), Illies and Takacs⁵ (185–400 nm), Nelson and Johnston⁷ (270–370 nm), Ganske et al.³ (200–370 nm), Furlan et al.² (190–450 nm), and Ghosh et al.⁴ (200–475 nm). The absorption spectrum has three broad overlapping bands, a weak band at ~300 nm and two stronger bands at ~215 nm and below 185 nm. In the range 220–280 nm, weak but distinct vibrational structure was observed by Furlan et al.² A major source of discrepancies in the data results from the presence of impurities. The recommended absorption cross sections in Table 4F-16 are taken from Ghosh et al. (rounded to 3 significant figures).

Ghosh et al. measured the ClNO₂ UV/vis spectrum temperature dependence over the range 210–296 K (the only temperature dependent study available). They parameterized the spectrum temperature dependence using the empirical formula:

$$\sigma(\lambda, T) = \sigma(\lambda, 296 \text{ K}) \times (1 + A(\lambda) \times (T - 296) + B(\lambda) \times (T - 296)^2)$$

The recommended fit parameters are included in Table 4F-16.

Photolysis Quantum Yield and Product Studies: Nelson and Johnston⁷ report a value of 0.93 ± 0.15 for $\Phi(\text{Cl})$ and $\Phi(\text{O}) < 0.02$ for photolysis at 350 nm. Carter et al.¹ reported the formation of NO₂ in the electronic ground state (yield 0.15 ± 0.05) and in the excited state (yield 0.85 ± 0.05) for 235 nm photolysis. Ghosh et al.⁴ report $\Phi(\text{O})$ values of 0.67 ± 0.12 and 0.15 ± 0.03 (2σ) for photolysis at 193 and 248 nm, respectively.

F17. ClONO (chlorine nitrite)[Back to Index](#)

(Recommendation: 78, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of chlorine nitrite, ClONO, was measured by Molina and Molina.¹ The absorption cross sections were determined by mass balance during the $\text{Cl}_2\text{O} + \text{ClNO} \rightarrow \text{Cl}_2 + \text{ClONO}$ reaction and isomerization of ClONO to ClNO₂. The recommended absorption cross sections in Table 4F-17 are taken from this study.

Photolysis Quantum Yield and Product Studies: It is assumed that the quantum yield for ClONO UV photolysis is unity. The Cl–O bond strength is only ~20 kcal mole⁻¹, so that chlorine atoms are likely photolysis products.

Table 4F-17. Recommended Absorption Cross Sections of ClONO at 231 K

λ (nm)	$10^{20} \sigma$ (cm ²)	λ (nm)	$10^{20} \sigma$ (cm ²)

F18. ClONO₂ (chlorine nitrate)[Back to Index](#)

(Recommendation: 06-2, Note: 15-10, Evaluated: 15-10)

Absorption Cross Sections: The recommended cross sections of chlorine nitrate, ClONO₂, are taken from the work of Burkholder et al. (196–432 nm, 220–296 K).² The cross section values are listed in Table 4F-18 together with the parameters needed to compute their temperature dependence. These values are in good agreement with those reported by Molina and Molina,¹⁰ which provided the basis for earlier recommendations and which supersedes the work of Rowland et al.¹⁵ An uncertainty factor in the room temperature cross sections of 1.1 (2σ) is estimated for the wavelength region 196 < λ < 432 nm.

Photolysis Quantum Yield and Product Studies: Several groups have investigated the identity of the primary photolytic fragments. Smith et al.¹⁶ report O + ClONO as the most likely products, using end-product analysis and steady-state photolysis. The results of Chang et al.,⁴ which were obtained using the very low-pressure photolysis (VLPPH) technique, indicate that the products are Cl + NO₃, with a quantum yield of 1.0 ± 0.2. Adler-Golden and Wiesenfeld,¹ using a flash photolysis atomic absorption technique, find O atoms to be the predominant photolysis product and report a quantum yield for Cl atom production of less than 4%. Marinelli and Johnston⁸ report a quantum yield for NO₃ production at 249 nm between 0.45 and 0.85, with a most likely value of 0.55; they monitored NO₃ by tunable dye laser absorption at 662 nm. Margitan⁷ used atomic resonance

fluorescence detection of O and Cl atoms and found the quantum yield at 266 nm and at 355 nm to be 0.9 ± 0.1 for Cl atom production and ~ 0.1 for O atom production, with no discernible difference at the two wavelengths. These results were confirmed by Knauth and Schindler,⁶ who used end-product analysis to infer the quantum yields from photolysis studies at 265 and 313 nm. Burrows et al.³ report also Cl and NO₃ as the photolysis products at 254 nm, with a quantum yield of unity within experimental error, and an O atom quantum yield of 0.24. In contrast, Nikolaisen et al.¹³ using broadband photolysis found that at $\lambda > 200$ nm the relative branching ratios are 0.61 ± 0.20 for the channel ClO + NO₂ and 0.39 ± 0.20 for the channel Cl + NO₃; in the $\lambda > 300$ nm region the quantum yields are found to be 0.44 ± 0.08 for production of ClO and NO₂ and 0.56 ± 0.08 for production of Cl and NO₃. Minton et al.,⁹ Nelson et al.,¹² and Moore et al.¹¹ made the first direct measurements of ClO and obtained comparable yields for the Cl + NO₃ and the ClO + NO₂ channels, using a molecular beam technique: at 193 nm they obtained respectively 0.64 ± 0.08 and 0.36 ± 0.08 , at 248 nm 0.54 ± 0.08 and 0.46 ± 0.08 , and at 308 nm 0.67 ± 0.06 and 0.33 ± 0.06 . These authors found no evidence for the O + ClONO channel and placed an upper limit for this channel of 0.04. Tyndall et al.¹⁷ observed quantum yields of 0.80 ± 0.08 and 0.28 ± 0.12 for Cl and ClO at 308 nm using resonance fluorescence detection methods and reported a O(³P) yield of ≤ 0.05 . Ravishankara,¹⁴ Goldfarb et al.,⁵ and Yokelson et al.¹⁸ have studied the photodissociation of ClONO₂ at 193, 222, 248 and 308 nm using atomic resonance fluorescence and time resolved absorption methods. They found that Cl and ClO are the two major dissociation products at 222, 248 and 308 nm, whereas at 193 nm, the quantum yield of O atoms was larger than the yield of ClO. At 193, 222, 248 and 308 nm, the yield of Cl was 0.53 ± 0.10 , 0.46 ± 0.10 , 0.41 ± 0.13 and 0.64 ± 0.20 , respectively; the O atom yield 0.73 ± 0.08 , 0.17 ± 0.08 , <0.10 and <0.05 ; and the ClO yield 0.29 ± 0.20 , 0.64 ± 0.20 , 0.39 ± 0.19 and 0.37 ± 0.19 . The NO₃ yield was determined by Yokelson et al.¹⁸ to be 0.93 ± 0.24 at 352.5 nm, 0.67 ± 0.09 at 308 nm, 0.60 ± 0.09 at 248 nm, and 0.18 ± 0.04 at 193 nm. In addition, Yokelson et al.¹⁸ measured the Cl atom yield as 0.73 ± 0.14 at 308 nm, 0.60 ± 0.12 at 248 nm and 0.45 ± 0.08 at 193 nm, and the O atom yield as <0.4 at 248 nm and <0.9 at 193 nm. Zou et al.¹⁹ determined absolute quantum yields for the Cl and ClO channels at 235 nm to be 0.42 ± 0.1 and 0.58 ± 0.1 , respectively, using molecular beam techniques and TOFMS/REMPL.

The recommended quantum yield values for production of Cl + NO₃ (Φ_1) and ClO + NO₂ (Φ_2) are given at the bottom of Table 4F-18 and are based on the work of Nelson et al.,¹² Moore et al.,¹¹ Nickolaisen et al.,¹³ Goldfarb et al.,⁵ and Yokelson et al.¹⁸ For wavelengths shorter than 308 nm the value of Φ_1 is 0.6 and Φ_2 is 0.4. For longer wavelengths Φ_1 increases linearly to 0.9 at 350 nm with the corresponding decrease in Φ_2 to 0.1. There is no evidence for production of O + ClONO in the more recent work; the production of O atoms reported in some of the earlier studies may have resulted from the decomposition of excited NO₃. Zou et al.¹⁹ determined the quantum yield of spontaneous decomposition of NO₃ into NO₂ + O to be 0.20 and into NO + O₂ to be 0.006.

Work by Nickolaisen et al.¹³ indicates that the photodissociation quantum yield is less than unity at wavelengths longer than ~ 330 nm because of the formation of a long-lived intermediate that may be quenched under atmospheric conditions (a situation analogous to that of Cl₂O).

F19. CCl₄ (carbon tetrachloride)[Back to Index](#)

(Recommendation: 15-10, Note: 15-10, Evaluated: 15-10)

Absorption Cross Sections: The VUV/UV absorption spectrum of carbon tetrachloride, CCl₄, has been measured at room temperature by Russell et al.¹⁵ (110–200 nm), Causley and Russell² (110–200 nm), Gordus and Bernstein⁵ (204–250 nm), Rowland and Molina¹³ (186–226 nm), Roxlo and Mandl¹⁴ (170–230 nm), Hubrich and Stuhl⁸ (160–275 nm), Ibuki et al.⁹ (105–210 nm), Hanf et al.⁶ (135 and 193 nm), Currie et al.⁴ (250 nm), Vanlaethem-Meurée et al.¹⁸ (190–252 nm), Simon et al.¹⁷ (174–250 nm), Prahlad and Kumar¹⁰ (186–240 nm), and Rontu Carlon et al.¹² (184.95, 202.206, 206.200, 213.857, and 228.8 nm atomic lines and 200–235 nm). The room temperature data agree to within 10% between 190 and 235 nm and to within 20% and 40% at 240 and 250 nm, respectively (except the value at 250 nm reported by Currie et al.⁴ that is significantly lower). The absorption spectrum of Prahlad and Kumar¹⁰ has irregular structure over the entire wavelength range presumably due to the experimental precision of the measurements. In the range 180–186 nm, the cross section values reported by Hubrich and Stuhl⁸ are higher by up to 25% than those reported by Simon et al.,¹⁷ and the value at 186 nm reported by Prahlad and Kumar¹⁰ is lower by 18% than the value of Simon et al. The value at 184.95 nm reported by Rontu Carlon et al. is in good agreement, to within 1.5%, with the NASA/JPL 10-6 recommendation. At the maximum near 176 nm Hubrich and Stuhl⁸ and Simon et al.¹⁷ report an absorption cross section of 1.01×10^{-17} cm². The peak cross section reported by Roxlo and Mandl¹⁴ is lower, $\sim 7 \times 10^{-18}$ cm². Rebbert and Ausloos¹¹ derived a cross section at 313 nm of $\leq 3.7 \times 10^{-26}$ cm² from the C₂H₅Cl yield in the photolysis of CCl₄-C₂H₆ mixtures.

The recommended room temperature absorption cross sections in Table 4F-19 are the mean of the values reported by Hubrich and Stuhl⁸ and Simon et al.¹⁷ in the region 174–192 nm, from Simon et al.¹⁷ in the region 194–198 nm, and from the revised cross section parameterization reported by Rontu Carlon et al. (see below) for the $200 \leq \lambda \leq 235$ nm region. Cross sections have been reported at longer wavelengths by Hubrich and Stuhl,⁸ although no recommendation is given for this region. For the wavelength region 174–190 nm the estimated uncertainty factor is 1.2 (2σ) and for the region $190 \leq \lambda \leq 235$ nm the estimated uncertainty factor is 1.06 (2σ).

The temperature dependence of the absorption spectrum has been measured by Currie et al.⁴ (250 nm) over the range 297–477 K, Vanlaethem-Meurée et al.¹⁸ (190–252 nm) at 279 and 296 K, Simon et al.¹⁷ (174–250 nm) over the range 225–295 K, Prahlad and Kumar¹⁰ (186–240 nm) over the range 220–300 K, and Rontu Carlon et al. (200–235 nm) over the range 210–350 K. The spectrum has a significant temperature dependence at wavelengths >205 nm where the cross sections decrease with decreasing temperature. Simon et al.¹⁷ parameterized the cross section temperature dependence using an empirical polynomial expansion:

$$\log_{10} \sigma(\lambda, T) = \sum A_n \lambda^n + (T-273) \times \sum B_n \lambda^n$$

and reported calculated cross section values for T = 210, 230, 250, 270, and 295 K. The parameters A_n and B_n, are valid for the temperature range 210–300 K and wavelength range 194–250 nm.

A ₀ = -37.104	B ₀ = 1.0739
A ₁ = -5.8218 × 10 ⁻¹	B ₁ = -1.6275 × 10 ⁻²
A ₂ = 9.9974 × 10 ⁻³	B ₂ = 8.8141 × 10 ⁻⁵
A ₃ = -4.6765 × 10 ⁻⁵	B ₃ = -1.9811 × 10 ⁻⁷
A ₄ = 6.8501 × 10 ⁻⁸	B ₄ = 1.5022 × 10 ⁻¹⁰

On the basis of their results, Rontu Carlon et al. used the same empirical formula and reported a revised spectrum parameterization with the coefficients given below. The parameterization is valid for the wavelength range 200–235 nm and temperature range 210–350 K and reproduces their experimental data to within 3%. For the wavelength region 174–200 nm, Simon et al. report a temperature independent spectrum, which is inconsistent with the Rontu Carlon et al. results obtained at 185 and 200 nm. The Rontu Carlon et al. parameterization is recommended.

n	A_n	B_n
0	1112.736208	-1.116511649
1	-22.02146808	0.02447268904
2	0.1596666745	-0.0001954842393
3	-0.0005104078676	$6.775547148 \times 10^{-7}$
4	$6.062440506 \times 10^{-7}$	$-8.621070147 \times 10^{-10}$

The VUV absorption spectrum of CCl₄ has been measured by Russell et al.¹⁵ (112–175 nm), Causley and Russell² (111–195 nm), Ibuki et al.⁹ (105–210 nm), Ho⁷ (4.9–200 nm), and Seccombe et al.¹⁶ (50–200 nm). Burton et al.¹ measured cross sections for the region 6.4–225 nm using dipole (e,e) spectroscopy. The agreement in the σ (Lyman- α , 298 K) values is to within ~15%. The recommended σ (Lyman- α , 298 K) is the average of the interpolated results from Causley and Russell, Ibuki et al., and Ho, 3.7×10^{-17} cm² molecule⁻¹, with an uncertainty factor of 1.2 (2 σ).

Photolysis Quantum Yield and Product Studies: Quantum yields ≥ 0.9 and ~ 0.75 for the photodissociative processes CCl₄ + h ν $\rightarrow$ CCl₃ + Cl at 213.9 nm and CCl₄ + h ν $\rightarrow$ CCl₂ + 2Cl at 163.3 nm, respectively, were derived from the gas-phase photolysis of CCl₄ in the presence of HCl, HBr, and C₂H₆ by Rebbert and Ausloos.¹¹ Clark and Husain³ report a quantum yield for Cl*(²P_{1/2}) atom formation in the broadband photolysis of CCl₄ to be 0.78 ± 0.27 . Hanf et al.⁶ reported Cl atom quantum yields in the photolysis of CCl₄ to be $\Phi(\text{Cl}) = 1.1 \pm 0.05$ and $\Phi(\text{Cl}^*) = 0.4 \pm 0.02$ (thus $\Phi(\text{Cl} + \text{Cl}^*) = 1.5 \pm 0.1$) at 193 nm and $\Phi(\text{Cl}) = 1.5 \pm 0.07$ and $\Phi(\text{Cl}^*) = 0.4 \pm 0.02$ (thus $\Phi(\text{Cl} + \text{Cl}^*) = 1.9 \pm 0.1$) at 135 nm. A quantum yield of unity with $\Phi(\text{Cl}) = 1$ is recommended.

Table 4F-19. Recommended Absorption Cross Sections of CCl₄ at 295 K

λ (nm)	$10^{20} \sigma$ (cm ²)	λ (nm)	$10^{20} \sigma$ (cm ²)

F20. CH_3OCl (methyl hypochlorite)

[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV/vis absorption spectrum of methyl hypochlorite, CH_3OCl , has been measured by Crowley et al.¹ (200–460 nm) and Jungkamp et al.² (230–400 nm). The spectrum has overlapping absorption bands with maxima at 230 and 310 nm. The agreement between the two data sets is good at wavelengths longer than 250 nm. At the maximum near 230 nm the cross sections from Jungkamp et al.² are about 15% smaller. The recommended cross sections in Table 4F-20 are the mean of the values reported by these two groups.

Photolysis Quantum Yield and Product Studies: Schindler et al.⁴ measured the quantum yield for the product channel $\text{Cl} + \text{CH}_3\text{O}$ to be 0.95 ± 0.05 at 308 nm. They also determined an upper limit of <0.01 for HCl formation at 248 nm and the ratio $\text{Cl}^*(^2\text{P}_{1/2})/\text{Cl}(^2\text{P}_{3/2})$ following photolysis at 235 and 238 nm to be 1.45 ± 0.05 . Krisch et al.³ used photofragment translational spectroscopy to confirm that photodissociation of CH_3OCl at 248 nm resulted in only the cleavage of the O-Cl bond and the formation of Cl and CH_3O .

Table 4F-20. Recommended Absorption Cross Sections of CH₃OCl at 295 K

λ (nm)	$10^{20} \sigma$ (cm ²)	λ (nm)	$10^{20} \sigma$ (cm ²)	λ (nm)	$10^{20} \sigma$ (cm ²)
230	14.9	290	1.32	350	0.662

F21. CHCl₃ (trichloromethane, chloroform)[Back to Index](#)

(Recommendation: 25-1, Note: 25-1, Evaluated: 25-1)

Absorption Cross Sections: The VUV/UV absorption spectrum of CHCl₃ (trichloromethane, chloroform) has been measured at room temperature by Gordus and Bernstein³ (222.7 nm), Tsubomura et al.¹⁰ (158–190, 175.5 nm), Lucazeau and Sandorfy⁶ (113–182 nm), Russell et al.⁷ (110–200 nm), Vanlaethem-Meurée et al.¹¹ (190–230 nm), Hubrich and Stuhl⁴ (160–255 nm), Lee and Suto⁵ (121.567, 105–221 nm), Simon et al.⁹ (174–240 nm), Brownsword et al.² (121.567 nm), Seccombe et al.⁸ (50–150 nm), and Vatsa and Volpp¹² (121.567 nm). The room temperature cross sections from Vanlaethem-Meurée et al. and Simon et al. are nearly identical in the wavelength region 190–210 nm. Differences of ~15% exist at longer wavelengths. The data of Hubrich and Stuhl and Simon et al. agree to within 10% between 180 and 234 nm. Differences of ~25% exist in the long wavelength tail with the values of Hubrich and Stuhl being larger. In the region of the absorption maximum at ~176 nm, the spread in the reported cross section values is the largest. Simon et al. report $\sigma(176 \text{ nm}) = \sim 5 \times 10^{-18} \text{ cm}^2$ compared to $3.7 \times 10^{-18} \text{ cm}^2$ reported by Hubrich and Stuhl and $< 2 \times 10^{-18} \text{ cm}^2$ by Lucazeau and Sandorfy. The recommended absorption cross sections in Table 4F-21 are only for wavelengths >180 nm and are the mean of the values reported by Hubrich and Stuhl and Simon et al. for the wavelength range 180–240 nm. For the wavelength range 242–256 nm the recommended cross sections are obtained by extrapolation, $\log \sigma(\lambda) = -1.2277 - 0.0844 \lambda$.

The temperature dependence of the absorption spectrum has been measured by Vanlaethem-Meurée et al.¹¹ (190–230 nm) at 279 and 296 K and Simon et al.⁹ (174–240 nm) over the range 225–295 K. The temperature dependence is significant for wavelengths >194 nm where the cross sections decrease with decreasing temperature. Simon et al.⁹ parameterized the cross section temperature dependence using an empirical polynomial expansion:

$$\log_{10} \sigma(\lambda, T) = \sum A_n \lambda^n + (T-273) \times \sum B_n \lambda^n$$

and reported calculated cross sections for T = 210, 230, 250, 270, and 295 K. The parameters A_n and B_n, valid for the temperature range 210–300 K and wavelength range 190–240 nm, given below are recommended.

A ₀ = 269.80	B ₀ = 3.7973
A ₁ = -6.0908	B ₁ = -7.0913 × 10 ⁻²
A ₂ = 4.7830 × 10 ⁻²	B ₂ = 4.9397 × 10 ⁻⁴
A ₃ = -1.6427 × 10 ⁻⁴	B ₃ = -1.5226 × 10 ⁻⁶
A ₄ = 2.0682 × 10 ⁻⁷	B ₄ = 1.7555 × 10 ⁻⁹

There are several measurements of the CHCl₃ absorption spectrum in the Lyman-α (121.567 nm) region as noted above. The cross section measurements are in good agreement, to within 20%, with the exception of the Lucazeau and Sandorfy⁶ value, which is a factor of 2.5 less. The recommended Lyman-α cross section is $3.5 \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$ with an uncertainty factor of 1.20 (2σ).

Photolysis Quantum Yield and Product Studies: Quantum yields for H atom formation have been measured by Brownsword et al.^{1,2} to be 0.23 ± 0.03 and 0.13 at 121.6 and 157.6 nm, respectively. H atom formation was not detected in the photolysis at 193.3 nm.

Table 4F-21. Recommended Absorption Cross Sections of CHCl₃ at 296 K

λ (nm)	$10^{20} \sigma$ (cm ²)	λ (nm)	$10^{20} \sigma$ (cm ²)	λ (nm)	$10^{20} \sigma$ (cm ²)

F22. CH₂Cl₂ (dichloromethane)[Back to Index](#)

(Recommendation: 25-1, Note: 25-1, Evaluated: 25-1)

Absorption Cross Sections: The VUV/UV absorption spectrum of dichloromethane, CH₂Cl₂, has been measured at room temperature by Gordus and Bernstein³ (213 nm), Tsubomura et al.¹⁰ (163–192 nm), Russell et al.⁸ (110–200 nm), Vanlaethem-Meurée et al.¹¹ (176–216 nm), Hubrich and Stuhl⁴ (160–255 nm), Lee and Suto⁶ (105–204 nm, graphical data), Orkin et al.⁷ (164–240 nm), Simon et al.⁹ (176–220 nm), Brownsword et al.² (Lyman-α, 121.6 nm), Vatsa and Volpp¹² (121.567 nm), and Lange et al.⁵ (115–216 nm). The room temperature data of Vanlaethem-Meurée et al. and Simon et al. are nearly identical. The cross sections of Hubrich and Stuhl are as much as 12% greater than those of Simon et al. in the 176–206 nm wavelength range. Differences of ~50% exist in the 185–220 nm range. The recommended absorption cross sections in Table 4F-22 are the mean of the values reported by Hubrich and Stuhl and Simon et al. for the wavelength range 176–220 nm. For wavelengths >220 nm the recommended cross sections are obtained by extrapolation, $\log \sigma(\lambda) = -2.1337 - 0.08439 \lambda$. The measured cross section values in this wavelength range from Hubrich and Stuhl are smaller by ~7% for wavelengths <230 nm and larger ~50% between 235 and 255 nm than the extrapolated values. The cross sections of Orkin et al. are systematically less than those of Hubrich and Stuhl⁴ in the 210–240 nm range.

The temperature dependence of the absorption spectrum has been measured by Vanlaethem-Meurée et al.¹¹ (176–216 nm) at 279 and 296 K and Simon et al.⁹ (176–220 nm) over the range 225–295 K. The temperature dependence is significant for wavelengths >190 nm where the cross sections decrease with decreasing temperature. Simon et al.⁹ parameterized the cross section temperature dependence using an empirical polynomial expansion:

$$\log_{10} \sigma(\lambda, T) = \sum A_n \lambda^n + (T-273) \times \sum B_n \lambda^n$$

and reported calculated cross sections for 210, 230, 250, 270, and 295 K. The parameters A_n and B_n, valid for the temperature range 210–300 K and wavelength range 176–220 nm, given below are recommended.

A ₀ = -1431.8	B ₀ = -3.1171
A ₁ = 27.395	B ₁ = 6.7874 × 10 ⁻²
A ₂ = -1.9807 × 10 ⁻¹	B ₂ = -5.5000 × 10 ⁻⁴
A ₃ = 6.3468 × 10 ⁻⁴	B ₃ = 1.9649 × 10 ⁻⁶
A ₄ = -7.6298 × 10 ⁻⁷	B ₄ = -2.6101 × 10 ⁻⁹

There are several measurements of the CH₂Cl₂ absorption spectrum in the Lyman-α (121.567 nm) region as noted above. The VUV spectrum in the Lyman-α region consists of diffuse band structure. The cross section measurements are in good agreement, to within 10%, with the exception of the Russell et al.⁸ value, which is ~15% less. The recommended Lyman-α cross section is 4 × 10⁻¹⁷ cm² molecule⁻¹ with an uncertainty factor of 1.10 (2σ).

Photolysis Quantum Yield and Product Studies: Quantum yields for H atom formation have been measured by Brownsword et al.^{1,2} to be 0.28 ± 0.03, 0.23, and 0.002 ± 0.001 at 121.6, 157.6, and 193.3 nm, respectively.

Table 4F-22. Recommended Absorption Cross Sections of CH₂Cl₂ at 298 K

λ (nm)	$10^{20} \sigma$ (cm ²)	λ (nm)	$10^{20} \sigma$ (cm ²)	λ (nm)	$10^{20} \sigma$ (cm ²)

F23. CH₃Cl (chloromethane, methyl chloride)[Back to Index](#)

(Recommendation: 06-2, Note: 25-1, Evaluated: 25-1)

Absorption Cross Sections: The UV absorption spectrum of CH₃Cl (chloromethane, methyl chloride) has been measured at room temperature by Russell et al.¹³ (110–200 nm), Robbins¹² (174–220 nm), Hubrich et al.⁷ (158–235 nm), Vanlaethem-Meurée et al.¹⁸ (186–216 nm), and Simon et al.¹⁵ (174–216 nm). The room temperature data generally agree to within 10% over the wavelength range 174–216 nm and the data of Vanlaethem-Meurée et al.¹⁸ and Simon et al.¹⁵ are nearly identical. The recommended absorption cross sections in Table 4F-23 are the mean of the values reported by Robbins,¹² Hubrich et al.,⁷ and Simon et al.¹⁵ in the range 174–184 nm, the mean of the values reported by Robbins,¹² Hubrich et al.,⁷ Vanlaethem-Meurée et al.,¹⁸ and Simon et al.¹⁵ in the range 186–216 nm, and the mean of the values reported by Robbins¹² and Hubrich et al.⁷ in the range 218–220 nm. For the wavelength range 222–236 nm the recommended values were obtained from a log-linear fit to the Hubrich et al.⁷ data in the range 200–235 nm, $\log \sigma(\lambda) = -0.24164 - 0.09743 \lambda$. The cross section uncertainty in the 190–230 nm region is estimated to be 1.15 (2σ).

The temperature dependence of the UV absorption spectrum has been measured by Hubrich et al.⁷ (158–235 nm) at 208 and 298 K, Vanlaethem-Meurée et al.¹⁸ (186–216 nm) at 255, 279, and 296 K, and Simon et al.¹⁵ (174–216 nm) over the range 225–295 K. The temperature dependence of the absorption cross sections is significant at wavelengths greater than 194 nm where the cross sections decrease with decreasing temperature. There is very good agreement in the values reported by Vanlaethem-Meurée et al.¹⁸ and Simon et al.¹⁵ Simon et al.¹⁵ parameterized the cross section temperature dependence using an empirical polynomial expansion:

$$\log_{10} \sigma(\lambda, T) = \sum A_n \lambda^n + (T-273) \times \sum B_n \lambda^n$$

and reported calculated cross sections for T = 210, 230, 250, 270, and 295 K. The parameters A_n and B_n, valid for the temperature range 210–300 K and wavelength range 174–216 nm, given below are recommended.

A ₀ = -299.80	B ₀ = -7.1727
A ₁ = 5.1047	B ₁ = 1.4837 × 10 ⁻¹
A ₂ = -3.3630 × 10 ⁻²	B ₂ = -1.1463 × 10 ⁻³
A ₃ = 9.5805 × 10 ⁻⁵	B ₃ = 3.9188 × 10 ⁻⁶
A ₄ = -1.0135 × 10 ⁻⁷	B ₄ = -4.9994 × 10 ⁻⁹

The VUV spectrum in the Lyman-α (121.567 nm) vicinity contains strong diffuse band structure with a maximum nearly coincident with Lyman-α. There is reasonable agreement, to within 30%, in the reported absorption cross sections in the Lyman-α wavelength region by Russell et al.,¹³ Lee and Suto,⁸ Olney et al.,¹⁰ Brownsword et al.,² Lochter et al.,⁹ Vatsa et al.,¹⁹ Eden et al.,³ and Raymonda et al.¹¹ and Truch et al.¹⁶ as reported in Lochter et al.⁹ Several studies have reported the spectrum in other regions of the VUV: Felps et al.⁴ (171.2 nm), Gedanken and Rowe⁵ (161–197 nm), Herzberg and Scheibe⁶ (174–190 nm), Shold and Rebbert¹⁴ (123.6 and 147.0 nm), Tsubomura et al.¹⁷ (160–188 nm), and Wu et al.²⁰ (18–76 nm). The recommended Lyman-α cross section of 8.8 × 10⁻¹⁷ cm² molecule⁻¹ is taken from the Brownsword et al.² study with an uncertainty factor of 1.15 (2σ).

Photolysis Quantum Yield and Product Studies: Quantum yields for H atom formation have been measured by Brownsword et al.^{1,2} to be 0.53 ± 0.05, 0.29, and 0.012 ± 0.006 at 121.6, 157.6, and 193.3 nm, respectively.

Table 4F-23. Recommended Absorption Cross Sections of CH₃Cl at 298 K

λ (nm)	$10^{20} \sigma$ (cm ²)	λ (nm)	$10^{20} \sigma$ (cm ²)	λ (nm)	$10^{20} \sigma$ (cm ²)

F24. CH₃CCl₃ (1,1,1-trichloroethane, methylchloroform)

[Back to Index](#)

CH₃CCl₃ + hv → Products

(1)

(Recommendation: 15-10, Note: 15-10, Evaluated: 15-10)

Absorption Cross Sections: The VUV/UV absorption spectrum of CH₃CCl₃ (1,1,1-trichloroethane, methylchloroform) has been measured at room temperature by Salomon et al.⁴ (147 nm), Hubrich and Stuhl² (160–255 nm), Vanlaethem-Meurée et al.⁵ (182–240 nm), and Nayak et al.³ (160–240 nm). Hubrich and Stuhl² corrected their measured spectrum between 170 and 190 nm for the presence of a 1,4-dioxane stabilizer, corrections were <10.7%. Nayak et al.³ also measured the absorption cross sections in the liquid-phase over the range 235–260 nm and used a wavelength shift procedure to derive the gas-phase cross section data in this wavelength range. The agreement of the room temperature data is within 20% in the region 165–205 nm. Between 210 and 240 nm, the data of Vanlaethem-Meurée et al.⁵ and Nayak et al.³ agree to within 15%, whereas the data from Hubrich and Stuhl² are 100–150% greater. The recommended absorption cross sections in Table 4F-24 are the mean of the values reported by Hubrich and Stuhl² and Nayak et al.³ in the range 170–180 nm, the mean of the values reported by Vanlaethem-Meurée et al.,⁵ Hubrich and Stuhl,² and Nayak et al.³ in the range 185–205 nm, and the mean of the values reported by Vanlaethem-Meurée et al.⁵ and Nayak et al.³ in the range 210–240 nm. For wavelengths >240 nm, the recommended values were obtained by extrapolation of the Nayak et al.³ data in the range 210–240 nm, $\log \sigma(\lambda) = -1.59792 - 0.08066 \lambda$. The values measured by Hubrich and Stuhl² in this wavelength range are greater by ~140% at 250 nm and less by ~80% at 255 nm than the recommended values. The cross section uncertainty in the 190–230 nm region is estimated to be 1.18 (2 σ), which encompasses the available data.

There are no Lyman- α cross section data available. A $\sigma(\text{Lyman-}\alpha)$ value of 7×10^{-17} cm² molecule⁻¹ is estimated with an uncertainty factor of 1.4 (2 σ).

The temperature dependence of the absorption spectrum has been measured by Vanlaethem-Meurée et al.⁵ (182–240 nm) over the range 220–295 K and Nayak et al.³ (160–240 nm) over the range 223–333 K. The temperature dependence of the absorption cross sections is significant at wavelengths >210 nm where the cross sections decrease with decreasing temperature. The studies of Nayak et al.³ and Vanlaethem-Meurée et al.⁵ are in good agreement. Vanlaethem-Meurée et al.⁵ parameterized the cross section temperature dependence using an empirical polynomial expansion:

$$\log_{10} \sigma(\lambda, T) = \sum A_n \lambda^n + (T-273) \times \sum B_n \lambda^n$$

and reported calculated cross sections for T = 210, 230, 250, 270, and 295 K. The parameters A_n and B_n, valid for the temperature range 210–300 K and wavelength range 182–240 nm, reported by Gillotay and Simon¹ and given below are recommended.

A ₀ = 341.085191	B ₀ = -1.660090
A ₁ = -7.273362	B ₁ = 3.079969 × 10 ⁻²
A ₂ = 5.498387 × 10 ⁻²	B ₂ = -2.106719 × 10 ⁻⁴
A ₃ = -1.827552 × 10 ⁻⁴	B ₃ = 6.264984 × 10 ⁻⁷
A ₄ = 2.238640 × 10 ⁻⁷	B ₄ = -6.781342 × 10 ⁻¹⁰

Photolysis Quantum Yield and Product Studies: No recommendation.

F26. CH₃CHClCH₃ (2-chloropropane)

[Back to Index](#)

CH₃CHClCH₃ + hν → Products

(1)

(Recommendation: 02-25, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The VUV/UV absorption spectrum of 2-chloropropane, CH₃CHClCH₃, has been measured by Gillotay and Simon.¹ The Gillotay and Simon¹ results are reported (erroneously) as CH₃CH₂ClCH₃, which presumably should be CH₃CHClCH₃. The recommended data are listed in Table 4F-26.

Photolysis Quantum Yield and Product Studies: No recommendation.

F28. CH₂ClCH₂CH₂Cl (1,3-dichloropropane)

[Back to Index](#)

(Recommendation: 02-25, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The VUV/UV absorption spectrum of 1,3-dichloropropane, CH₂ClCH₂CH₂Cl, has been measured by Russell et al.¹ (116–192 nm). No recommendation is given.

Photolysis Quantum Yield and Product Studies: No recommendation.

- (1) Russell, B. R.; Edwards, L. O.; Raymonda, J. W. Vacuum ultraviolet absorption spectra of the chloromethanes. *J. Am. Chem. Soc.* **1973**, 95, 2129-2133, doi:10.1021/ja00788a008.

F29. CH₂Cl(CH₂)₂CH₂Cl (1,4-dichlorobutane)

[Back to Index](#)

(Recommendation: 02-25, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The VUV/UV absorption spectrum of 1,4-dichlorobutane, CH₂Cl(CH₂)₂CH₂Cl, has been measured by Russell et al.¹ (129–188 nm). No recommendation is given.

Photolysis Quantum Yield and Product Studies: No recommendation.

- (1) Russell, B. R.; Edwards, L. O.; Raymonda, J. W. Vacuum ultraviolet absorption spectra of the chloromethanes. *J. Am. Chem. Soc.* **1973**, 95, 2129-2133, doi:10.1021/ja00788a008.

F30. CCl₂O (carbonyl dichloride, phosgene)

[Back to Index](#)

(Recommendation: 94-26, Note: 25-1, Evaluated: 25-1)

Absorption Cross Sections: The UV absorption spectrum of CCl₂O (carbonyl dichloride, phosgene) has been measured at room temperature by Chou et al.² (185–226 nm), Okabe⁹ (240–280 nm), Meller et al.⁸ (200–315 nm), Jäger et al.⁶ (172–220 nm), Okabe^{10,11} (147, 184.9, and 253.7 nm), Glicker and Okabe⁴ (229 and 254 nm), Gillotay et al.³ (166–308 nm), and Khamaganov et al.⁷ (185 nm). The spectrum shows a weak absorption band between 215 and 310 nm with the maximum at ~235 nm and a strong absorption band below 200 nm with the maximum at ~174 nm. The room temperature values reported in the various studies are in very good agreement, generally within 10%. An exception is in the region of the absorption minimum around 200 nm where the values of Jäger et al.⁶ are lower than those of Gillotay et al.³ by as much as 20%. In this region the values of Chou et al.² and Meller et al.⁸ are between those of Gillotay et al.³ and Jäger et al.⁶

The recommended absorption cross sections in Table 4F-30 are averages over 500 cm⁻¹ intervals of the values of Gillotay et al.³ in the region 168.10–173.15 nm, the mean of the values from Gillotay et al.³ and Jäger et al.⁶ in the region 174.65–182.65 nm, the mean of the values from Chou et al.,² Gillotay et al.,³ and Jäger et al.⁶ in the region 184.35–199.00 nm, the mean of the values of Chou et al.,² Gillotay et al.,³ Meller et al.,⁸ and Jäger et al.⁶ in the region 201.01–218.59 nm, the mean of the values from Chou et al.,² Gillotay et al.,³ and Meller et al.⁸ in the region 221.00–226.00 nm, and the mean of the values from Gillotay et al.³ and Meller et al.⁸ in the region 228.58–305.36 nm.

The temperature dependence of the absorption spectrum has been measured by Gillotay et al.³ (166–308 nm) over the range 210–295 K. The temperature dependence is significant only in the region <175 nm and >250 nm. The strong absorption band is shifted slightly to shorter wavelengths with decreasing temperature and a peak cross section increase of ~20% between 295 and 210 K. In the long wavelength region, the absorption cross sections decrease with decreasing temperature with a decrease of ~80% at 305 nm between 295 and 210 K.

Okake et al.¹² (117–159 nm, graphical) is the only available measurement of the CCl₂O absorption spectrum in the Lyman- α (121.567 nm) region. The recommended Lyman- α cross section is 7×10^{-17} cm² molecule⁻¹ with an estimated uncertainty factor of 1.4 (2 σ).

Photolysis Quantum Yield and Product Studies: Phosgene is a useful actinometer in the region 200–280 nm. The photodissociation processes CCl₂O + h ν $\rightarrow$ COCl + Cl with subsequent decay of the COCl radical, COCl $\rightarrow$ CO + Cl, produces CO with unity quantum yield (see Okabe,⁹ Wijnen,¹³ Heicklen,⁵ and Calvert and Pitts¹).

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of formyl chloride, HC(O)Cl , has been measured at room temperature by Libuda et al.¹ (239–307 nm). The absorption spectrum has a highly structured absorption band with a maximum near 260 nm. The recommended cross sections in Table 4F-31 are the averages over 1 nm intervals of the data from Libuda et al.¹ (0.7 nm resolution).

Photolysis Quantum Yield and Product Studies: No recommendation.

Table 4F-31. Recommended Absorption Cross Sections of HC(O)Cl at 298 K

F32. ClC(O)F (carbonyl chlorofluoride, fluorochlorophosgene)

[Back to Index](#)

(1)

(2)

(3)

(Recommendation: 94-26, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of ClC(O)F (carbonyl chlorofluoride, fluorochlorophosgene) has been measured at room temperature by Chou et al.¹ (186–226 nm), Hermann et al.² (193.4 nm), and Nölle et al.^{3,4} (200–262 nm). The spectrum has monotonically decreasing absorptions cross sections with increasing wavelength with a shoulder in the spectrum around 200 nm. The room temperature data are in good agreement in the common wavelength range with differences $\leq 6\%$. The recommended absorption cross sections in Table 4F-32-1 are the averages over the 500 cm^{-1} intervals used for atmospheric modeling of the data from Chou et al.¹ and Hermann et al.² in the region 186–199 nm, the mean of the data from Chou et al.,¹ and Nölle et al.^{3,4} at 201 and 203.1 nm, and the data from Nölle et al.^{3,4} at wavelengths $>205 \text{ nm}$.

The temperature dependence of the absorption spectrum was measured by Nölle et al.^{3,4} (200–262 nm) at 223, 248, 273, and 298 K. The cross sections decrease with decreasing temperature at wavelengths >210 nm with the magnitude of the difference increasing with increasing wavelength. At wavelengths <210 nm the cross sections increase with decreasing temperature with the difference in going from 298 to 223 K is ~18% at 201 nm.

Photolysis Quantum Yield and Product Studies: Photolysis quantum yields of ClC(O)F have been measured by Hermann et al.² and Nölle et al.⁴ The results are summarized in Table 4F-32-2. The relative distribution of the CO and CF₂O products was shown by Hermann et al.² to depend on the total pressure over the range 10 to 900 mbar. The apparent quantum yields were taken as the quantum yields for the decomposition into COF + Cl and CO + F + Cl since the parent molecule cannot be reformed (as in the case of CF₂O) and COCl is known to be unstable.

F33. CFCl₃ (fluorotrichloromethane, CFC-11)

[Back to Index](#)

CFCl₃ (CFC-11) + hν → Products

(1)

(Recommendation: 15-10, Note: 15-10, Evaluated: 15-10)

Absorption Cross Sections: The VUV/UV absorption spectrum of fluorotrichloromethane (CFC-11), CFCl₃, has been measured at room temperature by Gilbert et al.⁴ (60–145 nm), Doucet et al.³ (120–200 nm), Gordus and Bernstein⁵ (225 nm), Rowland and Molina¹⁴ (186–226 nm), Robbins and Stolarski¹³ (174–226 nm), Greene and Wayne⁶ (186–209 nm), Chou et al.¹ (185–226 nm), Hubrich et al.⁸ (158–260 nm), Hubrich and Stuhl⁷ (158–

260 nm), Vanlaethem-Meurée et al.¹⁶ (190–220 nm), Simon et al.¹⁵ (174–230 nm), Mérienne et al.¹² (200–238 nm), and McGillen et al.¹¹ (184.95–230 nm). Absorption cross sections in the region 148–225 nm have also been derived from electron energy loss measurements by Huebner et al.⁹, which are up to 30% higher than the values obtained by optical measurements. The room temperature data for wavelengths >180 nm are in good agreement, generally within 10–15%. The recommended absorption cross sections in Table 4F-33 are the values from Simon et al.¹⁵ in the region 174–188 nm, the values from the McGillen et al. parameterization (see below) in the region 190–230 nm, and the data from Hubrich and Stuhl⁷ in the region 235–260 nm. An uncertainty factor of 1.04 (2σ) is recommended for the 190–230 nm wavelength region.

A recommended Lyman-α cross section of $9.8 \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$ with an uncertainty factor of 1.20 (2σ) is taken from SPARC.¹⁰

The temperature dependence of the absorption spectrum was measured by Chou et al.¹ (185–226 nm) over the range 213–296 K, Hubrich et al.⁸ (158–260 nm) and Hubrich and Stuhl⁷ (158–260 nm) at 208 and 298 K, Vanlaethem-Meurée et al.¹⁶ (190–220 nm) at 255, 279, and 296 K, Simon et al.¹⁵ (174–230 nm) over the range 225–295 K, Mérienne et al.¹² (200–238 nm) at 220, 240, and 296 K, and McGillen et al.¹¹ (184.95–230 nm) at 5 temperatures between 216 and 296 K. The temperature dependence is significant at wavelengths above 185 nm where the cross sections decrease with decreasing temperature. Simon et al.¹⁵ parameterized their cross section temperature dependence using an empirical polynomial expansion:

$$\log_{10} \sigma(\lambda, T) = \sum A_n \lambda^n + (T-273) \times \sum B_n \lambda^n$$

and reported calculated cross sections for T = 210, 230, 250, 270, and 295 K. The parameters A_n and B_n, valid for the temperature range 210–300 K and wavelength range 174–230 nm are:

$$\begin{array}{ll} A_0 = -84.611 & B_0 = -5.7912 \\ A_1 = 7.9551 \times 10^{-1} & B_1 = 1.1689 \times 10^{-1} \\ A_2 = -2.0550 \times 10^{-3} & B_2 = -8.8069 \times 10^{-4} \\ A_3 = -4.4812 \times 10^{-6} & B_3 = 2.9335 \times 10^{-6} \\ A_4 = 1.5838 \times 10^{-8} & B_4 = -3.6421 \times 10^{-9} \end{array}$$

Mérienne et al.¹² used a similar polynomial expansion to fit their data to:

$$\ln \sigma(\lambda, T) = \sum a_n (\lambda-200)^n + (T-296) \times \sum b_n (\lambda-200)^n,$$

which is valid for the temperature range 220–296 K and wavelength range 200–238 nm. The reported a_n and b_n parameters are:

$$\begin{array}{ll} a_0 = -41.925548 & b_0 = 3.58977 \times 10^{-4} \\ a_1 = -1.142857 \times 10^{-1} & b_1 = 3.02973 \times 10^{-4} \\ a_2 = -3.12034 \times 10^{-3} & b_2 = -1.13 \times 10^{-8} \\ a_3 = 3.6699 \times 10^{-5} & \end{array}$$

McGillen et al.¹¹ used the polynomial expansion:

$$\log_{10} \sigma(\lambda, T) = \sum A_i (\lambda-200)^i + (T-273) \times \sum B_i (\lambda-200)^i$$

to fit their data. The fit is valid for the temperature range 216–296 K and wavelength range 190–230 nm and reproduces their experimental data to within 2%. The reported A_i and B_i parameters are given below. The fit is in good agreement with the Chou et al.¹ data set, to within 5%, in reasonable agreement with the Mérienne et al.¹² data set, differences of 8% or less, but shows systematic differences with the Simon et al. data set, with 15% differences for the data at 230 K. The McGillen et al. parameterization is recommended.

F34. CF₂Cl₂ (difluorodichloromethane, CFC-12)

[Back to Index](#)

(1)

(Recommendation: 15-10, Note: 15-10, Evaluated: 15-10)

Absorption Cross Sections: The VUV/UV absorption spectrum of difluorodichloromethane (CFC-12), CF₂Cl₂, has been measured at room temperature by Gordus and Bernstein⁵ (210 nm), Rowland and Molina¹⁴ (186–216 nm), Robbins and Stolarski¹³ (174–216 nm), Greene and Wayne⁶ (186–206 nm), Rebbert and Ausloos¹² (213.9 nm), Chou et al.¹ (184–221 nm), Hubrich et al.⁷ (159–240 nm), Vanlaethem-Meurée et al.¹⁷ (190–216 nm), Simon et al.¹⁶ (174–230 nm), and Mérienne et al.¹¹ (200–231 nm). The room temperature data are in good agreement, generally within 10–15%, except for data from Green and Wayne⁶ at wavelengths >195 nm and the data from Rowland and Molina¹⁴ near 210 nm. Absorption cross sections have also been derived from electron energy loss measurements by Huebner et al.⁸ (148–218 nm), which agree to within 10% with the data obtained by optical measurements around the absorption maximum but are larger than the optical cross section data at wavelengths >196 nm by as much as 100%. The recommended absorption cross sections in Table 4F-34 are values from Hubrich et al.⁷ in the region 170–172 nm, the mean of the values reported by Hubrich et al.⁷ and Simon et al.¹⁶ in the region 174–178 nm, the values from Simon et al.¹⁶ in the region 180–198 nm, mean of the values reported by Simon et al.¹⁶ and Mérienne et al.¹¹ in the region 200–226 nm, and the data of Mérienne et al.¹¹ in the region 228–230 nm. For the range 232–240 nm the recommended values were obtained from a log-linear fit and extrapolation of the Mérienne et al.¹¹ data, $\log \sigma(\lambda) = 2.1448 - 0.1061 \lambda$. The measured cross section values from Hubrich et al.⁷ over this wavelength range are lower by ~40% at 240 nm than the extrapolated values. An uncertainty factor of 1.08 (2σ) is recommended for the 190–230 nm wavelength region.⁹

High resolution absorption cross section measurements have been carried out by Secombe et al.¹⁵ (50–150 nm) and Limao-Vieira et al.¹⁰ (113–225 nm) using a synchrotron radiation light source. The results of Limao-Vieira et al.¹⁰ for the absorption band at 170–204 nm are in very good agreement with the recommendation in Table 4F-34. These cross section measurements significantly improve upon the earlier data from Gilbert et al.⁴ (60–135 nm) and Doucet et al.³ (120–200 nm).

The temperature dependence of the absorption spectrum has been measured by Rebbert and Ausloos¹² (213.9 nm) over the range 234–442 K, Chou et al.¹ (184–221 nm) at 212, 252, and 296 K, Hubrich et al.⁷ (159–240 nm) at 208 and 298 K, Vanlaethem-Meurée et al.¹⁷ (190–216 nm) at 255, 279, and 296 K, Simon et al.¹⁶ (174–230 nm) at 225–295 K, and Mérienne et al.¹¹ (200–231 nm) at 220, 240, and 296 K.

The temperature dependence is significant at wavelengths above 186 nm where the cross sections decrease with decreasing temperature. Mérienne et al.¹¹ parameterized the cross section temperature dependence using an empirical polynomial expansion:

$$\ln \sigma(\lambda, T) = \sum a_n (\lambda - 200)^n + (T - 296) \times \sum b_n (\lambda - 200)^n$$

that is valid for the temperature range 220–296 K and wavelength range 200–231 nm. The a_n and b_n parameters given below are recommended.

$$\begin{aligned} a_0 &= -43.8954569 & b_0 &= 4.8438 \times 10^{-3} \\ a_1 &= -2.403597 \times 10^{-1} & b_1 &= 4.96145 \times 10^{-4} \\ a_2 &= -4.2619 \times 10^{-4} & b_2 &= -5.6953 \times 10^{-6} \\ a_3 &= 9.8743 \times 10^{-6} \end{aligned}$$

Simon et al.¹⁶ also parameterized the cross section temperature dependence of their data. However, the parameters reported by Simon et al.¹⁶ contain typographical error(s) that were reproduced in NASA/JPL 02-25. The correct parameters are unknown and therefore not given here.

Photolysis Quantum Yield and Product Studies: Clark and Husain² report the quantum yield for Cl*(²P_{1/2}) atom formation in the broad band photolysis of CF₂Cl₂ to be 0.75 ± 0.26.

Table 4F-34. Recommended Absorption Cross Sections of CF₂Cl₂ at 298 K

λ (nm)	10 ²⁰ σ (cm ²)	λ (nm)	10 ²⁰ σ (cm ²)	λ (nm)	10 ²⁰ σ (cm ²)

F35. CF₃Cl (trifluorochloromethane, CFC-13)

[Back to Index](#)

(1)

(Recommendation: 02-25, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The VUV/UV absorption spectrum of trifluorochloromethane (CFC-13), CF₃Cl, has been measured at room temperature by Chou et al.¹ (184–203 nm), Vanlaethem-Meurée et al.⁸ (172–200 nm), Hubrich and Stuhl⁵ (160–220 nm), and Simon et al.⁷ (172–200 nm). The cross section values from Vanlaethem-Meurée et al.⁸ and Simon et al.⁷ are identical. The cross section data from Hubrich and Stuhl⁵ deviate from the Vanlaethem-Meurée et al.⁸ and Simon et al.⁷ values by $\pm 25\%$ and the data from Chou et al.¹ is systematically greater by 15–30% in the region 185–200 nm. The recommended absorption cross sections in Table 4F-35 are taken from Simon et al.⁷ for the range 172–200 nm. The recommended cross sections in the range 202–220 nm were obtained by a log-linear extrapolation of the Simon et al.⁷ data, $\log \sigma(\lambda) = -5.048 - 0.0834 \lambda$.

The absorption spectrum has been measured in the far UV by Gilbert et al.⁴ (65–130 nm), and Doucet et al.³ (120–160 nm), and Ravishankara et al.⁶ (Lyman- α , 121.6 nm).

The temperature dependence of the absorption spectrum was measured by Vanlaethem-Meurée et al.⁸ (172–200 nm) at 255, 279, and 296 K, Hubrich and Stuhl⁵ (160–220 nm) at 208 and 298 K, and Simon et al.⁷ (172–200 nm) over the range 225–295 K. Vanlaethem-Meurée et al.⁸ and Simon et al.⁷ reported no measurable temperature dependence. Hubrich and Stuhl⁵ report a decrease of the absorption cross sections at 208 K, 4% at 160 nm increasing to 74% at 205 nm. Simon et al.⁷ parameterized the cross section wavelength dependence and the temperature dependence using an empirical polynomial expansion:

$$\log_{10} \sigma(\lambda, T) = \sum A_n \lambda^n + (T-273) \times \sum B_n \lambda^n \text{ (with all } B_n = 0)$$

and reported calculated values at 295 K. The A_n parameters, which are valid for the temperature range 210–300 K and wavelength range 172–200 nm, given below are recommended.

$$\begin{aligned} A_0 &= -155.88 & A_1 &= 2.0993 \\ A_2 &= -1.0486 \times 10^{-2} & A_3 &= 1.6718 \times 10^{-5} \end{aligned}$$

Photolysis Quantum Yield and Product Studies: Clark and Husain² report a quantum yield for Cl*(²P_{1/2}) atom formation in the broad band photolysis of CF₃Cl to be 0.86 ± 0.29 .

F36. $\text{CCl}_2\text{FCCl}_2\text{F}$ (CFC-112)

[Back to Index](#)

(Recommendation: 19-5, Note: 19-5, Evaluated: 19-5)

Absorption Cross Sections: UV absorption cross sections of $\text{CCl}_2\text{FCCl}_2\text{F}$ (CFC-112, 1,1,2,2-tetrachloro-1,2-difluoroethane) have been measured by Davis et al.¹ (192.5–235 nm, 1 nm resolution). This is the only study of this molecule available at the time of this evaluation. Absorption cross sections were measured at 10 discrete wavelengths and 5 temperatures between 230 and 323 K. The measured spectra were corrected for a minor CFC-112a sample impurity, 4.0%, using the CFC-112a spectrum measured in their study. The UV absorption spectra of CFC-112 are continuous over this wavelength range with a decrease in cross section with increasing wavelength. A decrease in $\sigma(\lambda, T)$ with decreasing temperature was observed at all wavelengths with the temperature dependence greatest at the longer wavelengths.

The CFC-112 spectra were parameterized in Davis et al. using the formula:

$$\ln(\sigma(\lambda, T)) = \sum_i A_i \lambda_i^i + (T - 296) \sum_i B_i \lambda_i^i$$

(units: $\sigma(\lambda, T)$ ($\text{cm}^2 \text{ molecule}^{-1}$, base e), λ (nm), and T (K)) which reproduces the experimental data to within 2%, or better, over the wavelength range most critical for atmospheric photolysis, 195–215 nm. The parameterization coefficients from Davis et al. given below are valid for wavelengths from 192.5 to 235 nm and temperatures between 230 and 323 K.

i	A_i	B_i
0	-1488.6207	6.04688
1	18.43604	-0.0801501
2	-0.02897393	0.0001201698
3	-0.00051504703	2.610366×10^{-6}
4	2.644261×10^{-6}	$-1.3959106 \times 10^{-8}$
5	$-3.7258313 \times 10^{-9}$	$2.0719264 \times 10^{-11}$

The CFC-112 absorption cross sections given in Table 4F-36 were calculated using this parameterization. The recommended estimated uncertainty factor ($F(\lambda)$, 2σ) is 1.08 over the temperature and wavelength range of the experimental data.

Photolysis Quantum Yield and Product Studies: No recommendation.

[Back to Index](#)

CCl₃CClF₂ + hν → Products

(1)

(Recommendation: 19-5, Note: 19-5, Evaluated: 19-5)

Absorption Cross Sections: UV absorption cross sections of CCl₃CClF₂ (CFC-112a, 1,1,1,2-tetrachloro-2,2-difluoroethane) have been measured by Davis et al.¹ (192.5–235 nm, 1 nm resolution). This is the only study of this molecule available at the time of this evaluation. Absorption cross sections were measured at 10 discrete wavelengths and 5 temperatures between 230 and 323 K. The measured spectra were corrected for a minor CFC-112 sample impurity, 3.68%, using the CFC-112 spectrum measured in their study. The UV absorption spectra of CFC-112a are continuous over this wavelength range with a decrease in cross section with increasing wavelength. A decrease in $\sigma(\lambda, T)$ with decreasing temperature was observed at all wavelengths with the temperature dependence greatest at the longer wavelengths.

The CFC-112a spectra were parameterized in Davis et al. using the formula:

$$\ln(\sigma(\lambda, T)) = \sum_i A_i \lambda_i^i + (T - 296) \sum_i B_i \lambda_i^i$$

(units: $\sigma(\lambda, T)$ (cm² molecule⁻¹, base e), λ (nm), and T (K)) which reproduces the experimental data to within 2%, or better, over the wavelength range most critical for atmospheric photolysis, 195–215 nm. The parameterization coefficients reproduced from Davis et al. given below are valid for wavelengths between 192.5 and 235 nm and temperatures between 230 and 323 K.

F38. $\text{CF}_2\text{ClCFCl}_2$ (1,1,2-trifluoro-1,2,2-trichloroethane, CFC-113)

[Back to Index](#)

$\text{CF}_2\text{ClCFCl}_2$ (CFC-113) + $h\nu \rightarrow$ Products

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of 1,1,2-trifluoro-1,2,2-trichloroethane (CFC-113), $\text{CF}_2\text{ClCFCl}_2$, has been measured at room temperature by Chou et al.¹ (184–224 nm), Hubrich and Stuhl³ (160–250 nm), and Simon et al.⁴ (184–230 nm). The cross section values agree to within ~10% except in the region near 190 nm where the values of Hubrich and Stuhl³ are smaller by as much as 20%. The recommended absorption cross sections in Table 4F-38 are the values from Hubrich and Stuhl³ in the region 175–180 nm, the value at 184 nm was interpolated between those of Hubrich and Stuhl³ at 180 nm and Simon et al.⁴ at 186 nm, and the values from Simon et al.⁴ in the region 186–230 nm. The recommended absorption cross sections for

wavelengths >230 nm were obtained from a log-linear extrapolation of the Simon et al.⁴ data, $\log \sigma(\lambda) = -0.9860 - 0.0894 \lambda$. The values measured by Hubrich and Stuhl³ in the region >230 nm are greater than the extrapolated values by ~20–80%.

The absorption spectrum in the far UV has been measured by Doucet et al.² (110–200 nm).

The temperature dependence of the absorption spectrum has been measured by Hubrich and Stuhl³ (160–250 nm) at 208 and 298 K and Simon et al.⁴ (184–230 nm) over the range 225–295 K. The temperature dependence is significant at wavelengths >194 nm and <170 nm where the cross sections decrease with decreasing temperature. Simon et al.⁴ parameterized the temperature dependence of the cross sections using an empirical polynomial expansion:

$$\log_{10} \sigma(\lambda, T) = \sum A_n \lambda^n + (T-273) \times \sum B_n \lambda^n$$

and reported calculated values for T = 210, 230, 250, 270, and 295 K. The A_n and B_n parameters, valid over the temperature range 210–300 K and wavelength range 182–230 nm, given below are recommended.

$$\begin{array}{ll} A_0 = -1087.9 & B_0 = 12.493 \\ A_1 = 20.004 & B_1 = -2.3937 \times 10^{-1} \\ A_2 = -1.3920 \times 10^{-1} & B_2 = 1.7142 \times 10^{-3} \\ A_3 = 4.2828 \times 10^{-4} & B_3 = -5.4393 \times 10^{-6} \\ A_4 = -4.9384 \times 10^{-7} & B_4 = 6.4548 \times 10^{-9} \end{array}$$

Photolysis Quantum Yield and Product Studies: No recommendation.

F39. CCl₃CF₃ (CFC-113a)[Back to Index](#)

(Recommendation: 19-5, Note: 19-5, Evaluated: 19-5)

Absorption Cross Sections: UV absorption cross sections of CCl₃CF₃ (CFC-113a, 1,1,1-trichloro-2,2,2-trifluoroethane) have been measured by Davis et al.¹ (192.5–235 nm, 1 nm resolution). This is the only study of this molecule available at the time of this evaluation. Absorption cross sections were measured at 10 discrete wavelengths and 6 temperatures between 207 and 323 K. The UV absorption spectra of CFC-113a are continuous over this wavelength range with a decrease in cross section with increasing wavelength. A decrease in $\sigma(\lambda, T)$ with decreasing temperature was observed at nearly all wavelengths with the temperature dependence greatest at the longer wavelengths.

The CFC-113a spectra were parameterized in Davis et al. using the formula:

$$\ln(\sigma(\lambda, T)) = \sum_i A_i \lambda_i^i + (T - 296) \sum_i B_i \lambda_i^i$$

(units: $\sigma(\lambda, T)$ (cm² molecule⁻¹, base e), λ (nm), and T (K)) which reproduces the experimental data to within ~4%, or better, over the wavelength range most critical for atmospheric photolysis, 195–215 nm. The parameterization coefficients reproduced from Davis et al. below are valid for wavelengths between 192.5 and 235 nm and temperatures between 207 and 323 K.

<i>i</i>	<i>A_i</i>	<i>B_i</i>
0	-319.173	2.89174
1	2.70954	-0.0348043
2	0.00457404	3.6233×10^{-5}
3	-0.0001288147	1.08853×10^{-6}
4	4.71409×10^{-7}	-5.25744×10^{-9}
5	-5.35388×10^{-10}	7.26095×10^{-12}

The CFC-113a absorption cross sections given in Table 4F-39 were calculated using this parameterization. The recommended estimated uncertainty factors ($F(\lambda)$, 2σ) are assigned as $F(\lambda) = 1.05 + 1 \times 10^{-22}/\sigma(\lambda)$.

Photolysis Quantum Yield and Product Studies: No recommendation.

(1)

(Recommendation: 02-25, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The VUV/UV absorption spectrum of 1,1,2,2-tetrafluoro-1,2-dichloroethane (CFC-114), CF₂ClCF₂Cl, has been measured at room temperature by Chou et al.¹ (184–219 nm), Hubrich and Stuhl³ (160–235 nm), and Simon et al.⁵ (172–220 nm). The room temperature values of Simon et al.⁵ and Chou et al.¹ agree to within 5% except at 185 and 195 nm. The cross section values from Hubrich and Stuhl³ are systematically greater than those from Simon et al.⁵ The recommended absorption cross sections in Table 4F-40 are the values from Simon et al.⁵ in the region 172–220 nm. The recommended cross sections for wavelengths >220 nm were obtained from a log-linear extrapolation of the Simon et al.⁵ data, $\log \sigma(\lambda) = -1.8233 - 0.0913 \lambda$. The values measured by Hubrich et al.³ are greater by ~40% than the extrapolated values.

The absorption spectrum in the far UV has been measured by Ravishankara et al.⁴ (Lyman-α, 121.6 nm) and Doucet et al.² (110–190 nm).

The temperature dependence of the absorption spectrum has been measured by Hubrich and Stuhl³ (160–235 nm) at 208 and 298 K and Simon et al.⁵ (182–220 nm) in the range 225–295 K. Simon et al.⁵ report decreasing cross sections with decreasing temperature for wavelengths >190 nm. Hubrich and Stuhl³ report a small decrease of the cross sections (generally <10%) for wavelengths in the range 160–210 nm. Simon et al.⁵ parameterized the temperature dependence of the cross sections using an empirical polynomial expansion:

$$\log_{10} \sigma(\lambda, T) = \sum A_n \lambda^n + (T-273) \times \sum B_n \lambda^n$$

and reported calculated values for T = 210, 230, 250, 270, and 295 K. The A_n and B_n parameters, valid for the temperature range 210–300 K and wavelength range 172–220 nm, given below are recommended.

$$\begin{array}{ll} A_0 = -160.50 & B_0 = -1.5296 \\ A_1 = 2.4807 & B_1 = 3.5248 \times 10^{-2} \\ A_2 = -1.5202 \times 10^{-2} & B_2 = -2.9951 \times 10^{-4} \\ A_3 = 3.8412 \times 10^{-5} & B_3 = 1.1129 \times 10^{-6} \\ A_4 = -3.4373 \times 10^{-8} & B_4 = -1.5259 \times 10^{-9} \end{array}$$

Photolysis Quantum Yield and Product Studies: No recommendation.

F41. CCl₂FCF₃ (CFC-114a)

[Back to Index](#)

(Recommendation: 19-5, Note: 19-5, Evaluated: 19-5)

Absorption Cross Sections: UV absorption cross sections of CCl₂FCF₃ (CFC-114a, 1,2-dichlorotetrafluoroethane) have been measured by Davis et al.¹ (192.5–235 nm, 1 nm resolution). This is the only study of this molecule available at the time of this evaluation. Absorption cross sections were measured at 10 discrete wavelengths and 6 temperatures between 207 and 323 K. The UV absorption spectra of CFC-114a are continuous over this wavelength range with a decrease in cross section with increasing wavelength. A decrease in σ(λ,T) with decreasing temperature was observed at nearly all wavelengths with the temperature dependence greatest at the longer wavelengths.

The CFC-114a spectra were parameterized in Davis et al. using the formula:

$$\ln(\sigma(\lambda, T)) = \sum_i A_i \lambda_i^i + (T - 296) \sum_i B_i \lambda_i^i$$

(units: σ(λ,T) (cm² molecule⁻¹, base e), λ (nm), and T (K)) which reproduces the experimental data to within 5%, or better, over the wavelength range most critical for atmospheric photolysis, 195–215 nm. The parameterization coefficients from Davis et al. given below are valid for wavelengths between 192.5 and 235 nm and temperatures between 207 and 323 K.

<i>i</i>	<i>A_i</i>	<i>B_i</i>
0	-253.6338	0.52031

F42. CF₃CF₂Cl (pentafluorochloroethane, CFC–115)[Back to Index](#)

(1)

(Recommendation: 25-1, Note: 25-1, Evaluated: 25-1)

Absorption Cross Sections: The VUV/UV absorption spectrum of pentafluorochloroethane (CFC–115), CF₃CF₂Cl, has been measured at room temperature by Chou et al.¹ (184–207 nm), Hubrich and Stuhl³ (160–230 nm), and Simon et al.⁵ (172–204 nm). The room temperature cross section data of Simon et al.⁵ and Hubrich and Stuhl³ agree to within ~20% with the Hubrich and Stuhl³ values being systematically greater over the range 172–204 nm. The data of Chou et al.¹ are greater than those of Simon et al.⁵ by as much as 50%. The recommended absorption cross sections in Table 4F-42 are the mean of the values reported by Hubrich and Stuhl³ and Simon et al.⁵ in the region 172–204 nm. The recommended values for wavelengths >204 nm are the mean of the values measured by Hubrich and Stuhl³ and those obtained by extrapolating the Simon et al.⁵ data, $\log \sigma(\lambda) = -6.2191 - 0.0756 \lambda$, where the extrapolated values are greater than the values measured by Hubrich and Stuhl.³

The absorption spectrum has been measured in the VUV by Ravishankara et al.⁴ (Lyman-α, 121.6 nm), Doucet et al.² (120–175 nm), and Totterdill et al.⁶ (121.6 nm). The Ravishankara et al. and Totterdill et al. cross section data are in good agreement and a factor of ~7 less than reported by Doucet et al. An average of the Ravishankara et al. and Totterdill et al. cross section values is recommended, $4.42 \times 10^{-18} \text{ cm}^2 \text{ molecule}^{-1}$ with an estimated uncertainty factor of 1.2 (2σ).

The temperature dependence of the absorption spectrum has been measured by Hubrich and Stuhl³ (160–230 nm) at 208 and 298 K and Simon et al.⁵ (172–204 nm) over the range 225–295 K. No measurable temperature dependence was reported in these studies. Simon et al.⁵ parameterized the absorption cross sections using an empirical polynomial expansion:

$$\log_{10} \sigma(\lambda, T) = \sum A_n \lambda^n + (T-273) \times \sum B_n \lambda^n \text{ (with all } B_n = 0)$$

and reported calculated values for 295 K. The A_n parameters, which are valid for the temperature range 210–300 K and wavelength range 172–204 nm, given below are recommended.

$$\begin{array}{ll} A_0 = 5.8281 & A_1 = -2.990 \times 10^{-1} \\ A_2 = 1.3525 \times 10^{-3} & A_3 = -2.6851 \times 10^{-6} \end{array}$$

Photolysis Quantum Yield and Product Studies: No recommendation.

F43. CHFCl₂ (fluorodichloromethane, HCFC-21)

[Back to Index](#)

CHFCl₂ (HCFC-21) + h ν $\rightarrow$ Products

(1)

(Recommendation: 02-25, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of fluorodichloromethane (HCFC-21), CHFCl₂, has been measured at room temperature by Gordus and Bernstein³ (208 nm), Robbins and Stolarski⁷ (174–222 nm), Green and Wayne⁴ (184–205 nm), Rebbert et al.⁶ (213.9 nm), Hubrich et al.⁵ (158–235 nm), and Simon et al.⁸ (174–222 nm). The absorption cross section data from these groups are in good agreement, generally to within 15%, except those from Green and Wayne⁴ which deviate significantly. The data from Hubrich et al.⁵ also contain irregular values around 205 and 220 nm where the agreement is only ~40%. The recommended absorption cross sections in Table 4F-43 are the values of Simon et al.⁸ in the region 174–222 nm. The recommended values for wavelengths >222 nm were obtained from a log-linear extrapolation of the Simon et al.⁸ data, $\log \sigma(\lambda) = 0.9806 - 0.1013 \lambda$. The values measured by Hubrich et al.⁵ deviate from the extrapolated values significantly.

Measurements in the far UV at 60–120 nm have been reported by Gilbert et al.,² measurements at 120–200 nm by Doucet et al.,¹ and a measurement at 147 nm by Rebbert et al.⁶

The temperature dependence of the absorption spectrum has been measured by Hubrich et al.⁵ (158–235 nm) at 208 and 298 K and Simon et al.⁸ (174–222 nm) over the range 225–295 K. The temperature dependence is significant at wavelengths >190 nm where the cross sections decrease with decreasing temperature. Simon et al.⁸ parameterized the temperature dependence of the cross sections using an empirical polynomial expansion:

$$\log_{10} \sigma(\lambda, T) = \sum A_n \lambda^n + (T-273) \times \sum B_n \lambda^n$$

and reported calculated values for T = 210, 230, 250, 270, and 295 K. The A_n and B_n parameters, valid for the temperature range 210–300 K and wavelength range 174–222 nm, given below are recommended.

$$\begin{array}{ll} A_0 = -514.56 & B_0 = -3.0577 \\ A_1 = 8.7940 & B_1 = 6.6539 \times 10^{-2} \\ A_2 = -5.6840 \times 10^{-2} & B_2 = -5.3964 \times 10^{-4} \\ A_3 = 1.5894 \times 10^{-4} & B_3 = 1.9322 \times 10^{-6} \\ A_4 = -1.6345 \times 10^{-7} & B_4 = -2.5754 \times 10^{-9} \end{array}$$

Photolysis Quantum Yield and Product Studies: No recommendation.

F44. CHF₂Cl (difluorochloromethane, HCFC–22)

[Back to Index](#)

CHF₂Cl (HCFC–22) + *hν* → Products

(1)

(Recommendation: 25-1, Note: 25-1, Evaluated: 25-1)

Absorption Cross Sections: The UV absorption spectrum of difluorochloromethane (CHF₂Cl, HCFC-22) has been measured at room temperature by Robbins and Stolarski⁷ (174–202 nm), Green and Wayne⁴ (181–194 nm, graphical data), Hubrich et al.⁵ (158–220 nm), Simon et al.⁸ (174–204 nm), and Cantrell et al.¹ (184.9 nm, 7.46×10^{-21} cm² molecule⁻¹). The results of Robbins and Stolarski,⁷ Hubrich et al.,⁵ and Simon et al.⁸ are in agreement, generally to within 15–20%. However, the data from Green and Wayne⁴ deviate significantly. The recommended absorption cross sections in Table 4F-44 are the values from Hubrich et al.⁵ in the region 170–172 nm and the values from Simon et al.⁸ in the region 174–204 nm. The recommended absorption cross sections for wavelengths >204 nm were obtained from a log-linear extrapolation of the Simon et al.⁸ data, $\log \sigma(\lambda) = -4.1001 - 0.0870 \lambda$. The measured values of Hubrich et al.⁵ deviate from the extrapolated values by as much as 20%.

The absorption spectrum has been measured in the VUV by Gilbert et al.³ (60–160 nm), Doucet et al.² (120–200 nm), Vatsa and Volpp⁹ (121.567 nm), and Limão-Vieira et al.⁶ (116–225 nm). A Lyman-α (121.567 nm) cross section of 1.75×10^{-17} cm² molecule⁻¹ is recommended from an average of the Vatsa and Volpp and Limão-Vieira et al. data. An uncertainty factor of 1.2 (2σ) is assigned.

The temperature dependence of the absorption spectrum has been measured by Hubrich et al.⁵ (158–220 nm) at 208 and 298 K and Simon et al.⁸ (174–204 nm) over the range 225–295 K. A weak temperature dependence was observed for wavelengths >190 nm where the cross sections decrease with decreasing temperature. Simon et al.⁸ parameterized the cross sections temperature dependence using an empirical polynomial expansion:

$$\log_{10} \sigma(\lambda, T) = \sum A_n \lambda^n + (T-273) \times \sum B_n \lambda^n$$

and reported calculated cross section values for T = 210, 230, 250, 270, and 295 K. The A_n and B_n parameters, valid for the temperature range 210–300 K and wavelength range 174–204 nm, given below are recommended.

$$\begin{array}{ll} A_0 = -106.029 & B_0 = -1.3399 \times 10^{-1} \\ A_1 = 1.5038 & B_1 = 2.7405 \times 10^{-3} \\ A_2 = -8.2476 \times 10^{-3} & B_2 = -1.8028 \times 10^{-5} \\ A_3 = 1.4206 \times 10^{-5} & B_3 = 3.8504 \times 10^{-8} \end{array}$$

Photolysis Quantum Yield and Product Studies: No recommendation.

F45. CH₂FCI (fluorochloromethane, HCFC-31)

[Back to Index](#)

CH₂FCI (HCFC-31) + hv → Products

(1)

(Recommendation: 02-25, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The absorption spectrum of fluorochloromethane (HCFC-31), CH₂FCI, has been measured at 208 and 298 K over the wavelength range 160–230 nm by Hubrich and Stuhl.³ The recommended room temperature cross sections from this study are listed in Table 4F-45.

The absorption spectrum has been measured in the far UV by Gilbert et al.² (60–120 nm) and Doucet et al.¹ (120–200 nm). The cross section values reported by Doucet et al. are significantly greater than those of Hubrich and Stuhl³ for the common wavelength region.

Photolysis Quantum Yield and Product Studies: No recommendation.

F46. CHCl₂CClF₂ (HCFC-122)[Back to Index](#)

(1)

(Recommendation: 19-5, Note: 19-5, Evaluated: 19-5)

Absorption Cross Sections: UV absorption cross sections of CHCl₂CClF₂ (HCFC-122, 1,1-difluoro-1,2,2-trichloroethane) have been measured at room temperature by Minamikawa et al.¹ (298 K, 115–190 nm, 4 nm resolution) and Orkin et al.² (295 K, 190–216 nm, 0.5 nm resolution). The agreement between these two studies at 190 nm is good, to within 5%. The 185 nm cross section from the Minamikawa et al. study and the 190–216 nm cross sections at 2 nm intervals from Orkin et al. given in Table 4F-46 are recommended. The recommended estimated uncertainty factors ($F(\lambda)$, 2σ) are assigned as $F(\lambda) = 1.10 + 2 \times 10^{-21}/\sigma(\lambda)$.

The VUV absorption spectrum has been measured by Minamikawa et al.¹ (115–190 nm, 4 nm resolution). The Lyman- α (121.567 nm) cross section derived from this study, 6.43×10^{-17} cm² molecule⁻¹, is recommended with an uncertainty factor (2σ) of 1.2.

Photolysis Quantum Yield and Product Studies: No recommendation.

F48. CF₃CHCl₂ (1,1,1-trifluoro-2,2-dichloroethane, HCFC-123)

[Back to Index](#)

CF₃CHCl₂ (HCFC-123) + hν → Products

(1)

(Recommendation: 25-1, Note: 25-1, Evaluated: 25-1)

Absorption Cross Sections: The absorption spectrum of 1,1,1-trifluoro-2,2-dichloroethane (CF₃CHCl₂, HCFC-123) has been measured at room temperature by Green and Wayne² (185–204 nm), Gillotay and Simon¹ (170–250 nm), Orlando et al.⁵ (190–230 nm), Nayak et al.³ (160–230 nm), and Orkin et al.⁴ (190–240 nm). The absorption cross sections are within 25% of each other in the region below 220 nm with the exception of the Green and Wayne data that are significantly lower at wavelengths <200 nm. The recommended absorption cross sections in Table 4F-48 are the mean of the values reported by Gillotay and Simon¹ and Nayak et al. in the region 170–188 nm and the mean of the values reported by Gillotay and Simon, Orlando et al., Nayak et al., and Orkin et al. in the region 190–230 nm. The recommended cross sections for wavelengths >230 nm were obtained using a log-linear extrapolation of the Orlando et al. data, $\log \sigma(\lambda) = -3.1097 - 0.0794 \lambda$.

The temperature dependence of the absorption spectrum has been reported by Gillotay and Simon¹ (170–250 nm) at 225–295 K, Orlando et al.⁵ (190–230 nm) over the range 203–295 K, and Nayak et al.³ (160–230 nm) over the range 223–333 K. These studies report a decrease of the absorption cross sections with decreasing temperature at wavelengths >180 nm and <170 nm. Between 170–180 nm, an increase in the cross section with decreasing temperature was reported by Gillotay and Simon¹ and Nayak et al.³ An irregular temperature dependence was reported by Orlando et al.⁵ for the range 210–230 nm.

Various empirical functional forms have been proposed to parameterize the temperature dependence of the absorption cross sections. Gillotay and Simon¹ parameterized the cross sections and the temperature dependence using the polynomial expansion:

$$\log_{10} \sigma(\lambda, T) = \sum A_n \lambda^n + (T-273) \times \sum B_n \lambda^n$$

and report calculated cross section values for 210, 230, 250, 270, and 295 K. The A_n and B_n parameters, valid for the temperature range 210–300 K and wavelength range 182–250 nm, are given below.

$$\begin{array}{ll} A_0 = -513.996354 & B_0 = 1.757133 \\ A_1 = 9.089141 & B_1 = -3.499205 \times 10^{-2} \\ A_2 = -6.136794 \times 10^{-2} & B_2 = 2.593563 \times 10^{-4} \\ A_3 = 1.814826 \times 10^{-4} & B_3 = -8.489357 \times 10^{-7} \\ A_4 = -1.999514 \times 10^{-7} & B_4 = 1.037756 \times 10^{-9} \end{array}$$

Nayak et al.³ used a sixth-order polynomial of the form:

$$\log_{10}(\sigma_T) = \sum C_n (\lambda - 170)^n$$

for the temperatures measured in their study for the wavelength range 160–230 nm. The C_n parameters are listed below.

	223 K	273 K	295 K	333 K
C_0	-17.6732	-17.6773	-17.6792	-17.6722
C_1	1.70233×10^{-2}	1.3636×10^{-2}	1.19392×10^{-2}	9.07941×10^{-3}
C_2	-7.39366×10^{-4}	-4.98553×10^{-4}	-3.71661×10^{-4}	-1.29566×10^{-4}
C_3	-1.83761×10^{-4}	-1.70566×10^{-4}	-1.61218×10^{-4}	-1.56667×10^{-4}
C_4	7.80778×10^{-6}	6.73373×10^{-6}	6.03101×10^{-6}	5.56409×10^{-6}
C_5	-1.29836×10^{-7}	-1.02726×10^{-7}	-8.76762×10^{-8}	-7.77379×10^{-8}
C_6	8.05415×10^{-10}	5.66688×10^{-10}	4.61745×10^{-10}	3.93859×10^{-10}

Orlando et al.⁵ used the expression:

$$\ln \sigma(\lambda, T) = \sum (\sum a_{ij} (T - 245.4)^{j-1}) (\lambda - 206.214)^{i-1}, \quad i = 1-4, j = 1-3$$

that is valid for the temperature range 203–295 K and wavelength range 190–230 nm. The coefficients are given below.

$$\begin{array}{lll} a_{11} = -4.500 \times 10^1 & a_{12} = 3.529 \times 10^{-3} & a_{13} = -4.181 \times 10^{-8} \\ a_{21} = -1.985 \times 10^{-1} & a_{22} = 6.826 \times 10^{-5} & a_{23} = 1.555 \times 10^{-6} \\ a_{31} = -2.802 \times 10^{-4} & a_{32} = -1.018 \times 10^{-5} & a_{33} = 4.037 \times 10^{-8} \\ a_{41} = 6.312 \times 10^{-5} & a_{42} = -3.055 \times 10^{-7} & a_{43} = -2.473 \times 10^{-9} \end{array}$$

Photolysis Quantum Yield and Product Studies: No recommendation.

F49. CHClFCClF₂ (HCFC-123a)

[Back to Index](#)

(Recommendation: 19-5, Note: 19-5, Evaluated: 19-5)

Absorption Cross Sections: UV absorption cross sections of CHClFCClF₂ (HCFC-123a, 1,1,2-trifluoro-1,2-dichloroethane) have been measured at room temperature by Doucet et al.¹ (159–200 nm) and Orkin et al.² (190–220 nm, 0.5 nm resolution). The agreement between these studies in the wavelength range 190 to 200 nm is poor with the Doucet et al. study reporting cross sections at 200 nm a factor of 50 greater than obtained in the Orkin et al. study. The spectrum reported in the Orkin et al. study is deemed more reliable because of the consistency with the trends in HCFC absorption spectra and the agreement of spectra measured for other HCFCs (measured in theirs and other laboratories). The recommended cross sections given in Table 4F-49 at 2 nm intervals between 190 and 220 nm are taken from the Orkin et al. study. The recommended estimated uncertainty factors (F(λ), 2σ) are assigned as F(λ) = 1.10 + 2 × 10⁻²³/σ(λ).

The VUV absorption spectrum of HCFC-123a has been reported over two wavelength ranges by Doucet et al (120–158 nm and 159–200 nm) with a Lyman-α (121.567 nm) cross section of ~3 × 10⁻¹⁷ cm² molecule⁻¹. Because of the large discrepancy with the Orkin et al. study at longer wavelengths, a Lyman-α cross section is not recommended.

Photolysis Quantum Yield and Product Studies: No recommendation.

F50. CF₃CHFCl (1,1,1,2-tetrafluoro-2-chloroethane, HCFC-124)

[Back to Index](#)

CF₃CHFCl (HCFC-124) + hν → Products

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The absorption spectrum of 1,1,1,2-tetrafluoro-2-chloroethane (HCFC-124), CF₃CHFCl, has been measured by Orlando et al.² (190–230 nm) over the range 203–295 K and Gillotay and Simon¹ (170–230 nm) over the range 210–295 K. The absorption cross sections from these studies agree to better than 10% between 190 and 220 nm. At wavelengths >220 nm the values of Orlando et al.² are greater than those of Gillotay and Simon¹ by as much as 133%. The recommended room temperature cross sections in Table 4F-50 are the values of Gillotay and Simon¹ in the region 170–188 nm and 222–230 nm and the mean of the values reported by Gillotay and Simon¹ and Orlando et al.² in the region 190–220 nm.

The absorption cross sections decrease with decreasing temperature. An irregular temperature behavior was reported by Orlando et al.² for the range 215–230 nm where the absorption spectra show wiggles. Gillotay and Simon¹ parameterized the cross sections and the temperature dependence using an empirical polynomial expansion:

$$\log_{10} \sigma(\lambda, T) = \sum A_n \lambda^n + (T-273) \times \sum B_n \lambda^n$$

and reported calculated cross section values for T = 210, 230, 250, 270, and 295 K. The A_n and B_n parameters, valid for the temperature range 210–300 K and wavelength range 170–230 nm, are given below.

$$\begin{array}{ll} A_0 = -101.230250 & B_0 = -5.795712 \times 10^{-2} \\ A_1 = 1.333519 & B_1 = 1.053901 \times 10^{-3} \\ A_2 = -6.888672 \times 10^{-3} & B_2 = -6.530379 \times 10^{-6} \\ A_3 = 1.114172 \times 10^{-5} & B_3 = 1.382056 \times 10^{-8} \end{array}$$

Orlando et al.² report a parameterization using the expression:

$$\ln \sigma(\lambda, T) = \sum (\sum a_{ij} (T-251.7)^{j-1}) (\lambda-206.214)^{i-1}, \quad i = 1-4, j = 1-3$$

for the temperature range 203–295 K and wavelength range 190–230 nm. The reported coefficients are given below.

$$\begin{array}{lll} a_{11} = -4.967 \times 10^1 & a_{12} = 6.562 \times 10^{-3} & a_{13} = 1.735 \times 10^{-5} \\ a_{21} = -2.025 \times 10^{-1} & a_{22} = 2.788 \times 10^{-4} & a_{23} = -3.974 \times 10^{-6} \\ a_{31} = 6.839 \times 10^{-4} & a_{32} = 5.523 \times 10^{-6} & a_{33} = -3.092 \times 10^{-7} \\ a_{41} = 1.275 \times 10^{-4} & a_{42} = -2.959 \times 10^{-7} & a_{43} = -1.182 \times 10^{-8} \end{array}$$

Photolysis Quantum Yield and Product Studies: No recommendation.

F51. CH₂FCCL₂F (HCFC-132c)[Back to Index](#)

(1)

(Recommendation: 19-5, Note: 19-5, Evaluated: 19-5)

Absorption Cross Sections: UV absorption cross sections of CH₂FCCL₂F (HCFC-132c, 1,2-difluoro-2,2-dichloroethane) have been measured at room temperature, 295 K, by Orkin et al.¹ (190–240 nm, 0.5 nm resolution), the only study available at the time of this evaluation. The cross sections from the Orkin et al. study are recommended and given in Table 4F-51 at 2 nm intervals. The recommended estimated uncertainty factors ($F(\lambda)$, 2σ) are assigned as $F(\lambda) = 1.10 + 1 \times 10^{-23}/\sigma(\lambda)$.

Photolysis Quantum Yield and Product Studies: No recommendation.

F52. CF₃CH₂Cl (1,1,1-trifluoro-2-chloroethane, HCFC-133a)

[Back to Index](#)

(1)

(Recommendation: 25-1, Note: 25-1, Evaluated: 25-1)

Absorption Cross Sections: The absorption spectrum of 1,1,1-trifluoro-2-chloroethane (CF₃CH₂Cl, HCFC-133a) has been measured at room temperature by Ichimura et al.³ (147 nm, σ = 1.35 × 10⁻¹⁷ cm² molecule⁻¹), Green and Wayne¹ (186–203 nm), Hubrich and Stuhl² (160–245 nm), and McGillen et al.⁴ (185–240 nm). The agreement in the absorption cross sections for wavelengths >180 nm is poor. The recommended absorption cross sections in Table 4F-52 are taken from McGillen et al.

The HCFC-133a UV spectrum temperature dependence has been measured by Hubrich and Stuhl (160–245 nm, 208 K) and McGillen et al. (185–240 nm, 213, 233, 253, 294 and 323 K). McGillen et al. provided a parameterization of the temperature dependence valid over the wavelength range 192.5 to 240 nm for temperatures between 213 and 323 K:

$$\ln(\sigma(\lambda, T)) = \sum A_i (\lambda - 200)^i + (T - 273) \sum B_i (\lambda - 200)^i$$

with the A_i and B_i parameters given below:

i	A _i	B _i
0	-46.3107	0.003221
1	-0.18043	0.0001133
2	-0.000599	2.835 × 10 ⁻⁶
3	2.4743 × 10 ⁻⁵	8.007 × 10 ⁻⁷
4	2.9 × 10 ⁻⁶	-6.790755 × 10 ⁻⁸
5	-7.149 × 10 ⁻⁸	1.2007 × 10 ⁻⁹

Photolysis Quantum Yield and Product Studies: No recommendation.

F53. CH₃CFCl₂ (1,1,1-fluorodichloroethane, HCFC-141b)

[Back to Index](#)

(1)

(Recommendation: 25-1, Note: 25-1, Evaluated: 25-1)

Absorption Cross Sections: The UV absorption spectrum of 1,1,1-fluorodichloroethane (CH₃CFCl₂, HCFC-141b) has been measured over the temperature range 210–295 K by Gillotay and Simon² (170–240 nm), over the temperature range 203–295 K by Talukdar et al.⁴ (190–230 nm), and at room temperature by Fahr et al.¹ (298 K, 190–240 nm), and Orkin et al.³ (295 K, 190–240 nm). Fahr et al.¹ also measured the absorption spectrum in the liquid-phase and used a wavelength-shift procedure to derive cross sections for the gas-phase. The agreement between the cross section values reported by Gillotay and Simon,² Fahr et al.,¹ and Orkin et al.³ for the 190–240 nm region is good (1–10% up to 236 nm). The agreement of the results from Talukdar et al.⁴ are not as good. Their absorption cross sections are smaller at wavelengths <210 nm by as much as ~20% and are greater at wavelengths >210 nm by as much as 70%. The recommended absorption cross sections in Table 4F-53 are the values of Gillotay and Simon in the region 170–188 nm and the mean of the values reported by Gillotay and Simon, Fahr et al., and Orkin et al. in the region 190–240 nm. An estimated cross section uncertainty factor of 1.2 (2σ) is recommended for the data given in Table 4F-53.

A decrease of the absorption cross sections with decreasing temperature for wavelengths >188 nm and <172 nm was reported by Gillotay and Simon.² An increase in the cross sections with decreasing temperature was observed between 172 and 188 nm. Gillotay and Simon² parameterized the cross sections and the temperature dependence of the absorption cross sections using an empirical polynomial expansion:

$$\log_{10} \sigma(\lambda, T) = \sum A_n \lambda^n + (T-273) \times \sum B_n \lambda^n.$$

and report calculated cross section values for T = 210, 230, 250, 270, and 295 K. The A_n and B_n parameters, valid for the temperature range 210–300 K and wavelength range 172–240 nm, given below are recommended.

$$\begin{array}{ll} A_0 = -682.913042 & B_0 = 4.074747 \\ A_1 = 12.122290 & B_1 = -8.053899 \times 10^{-2} \\ A_2 = -8.187699 \times 10^{-2} & B_2 = 5.946552 \times 10^{-4} \\ A_3 = 2.437244 \times 10^{-4} & B_3 = -1.945048 \times 10^{-6} \\ A_4 = -2.719103 \times 10^{-7} & B_4 = 2.380143 \times 10^{-9} \end{array}$$

A Lyman-α (121.567 nm) cross section of 6.6 × 10⁻¹⁷ cm² molecule⁻¹ from the Vatsa and Volpp⁵ study, the only study available, is recommended. An uncertainty factor of 1.25 (2σ) is recommended.

Photolysis Quantum Yield and Product Studies: No recommendation.

F54. CH₃CF₂Cl (1,1,1-difluorochloroethane, HCFC-142b)

[Back to Index](#)

(Recommendation: 25-1, Note: 25-1, Evaluated: 25-1)

Absorption Cross Sections: The absorption spectrum of 1,1,1-difluorochloroethane (CH₃CF₂Cl, HCFC-142b) has been measured at room temperature by Doucet et al.³ (120–180 nm), Green and Wayne⁵ (184–201 nm), Hubrich and Stuhl⁶ (160–230 nm), Gillotay and Simon⁴ (170–230 nm), Orlando et al.⁸ (190–230 nm), and Nayak et al.⁷ (160–210 nm). For wavelengths <200 nm, the cross sections reported by Hubrich and Stuhl⁶ and Nayak et al.⁷ agree to within 15%, while those by Gillotay and Simon⁴ and Orlando et al.⁸ are systematically smaller by as much as 30%. Over the wavelength range 200–215 nm, the values of Gillotay and Simon,⁴ Orlando et al.,⁸ and Nayak et al.⁷ agree to within 15%. For wavelengths >215 nm, the absorption spectrum reported by Orlando et al.⁸ has deviations of up to 100% from the data of Gillotay and Simon.⁴ The values reported by Hubrich and Stuhl⁶ in the range 205–230 nm have increasingly larger deviations from the values reported by Gillotay and Simon⁴ with increasing wavelength. The results of Green and Wayne⁵ are significantly different from all the other data sets and are not considered in the recommendation. The recommended room temperature absorption cross sections in Table 4F-54 are the mean of the values reported by Hubrich and Stuhl,⁶ Gillotay and Simon,⁴ and Nayak et al.⁷ in the region 170–185 nm, the mean of the values reported by Gillotay and Simon,⁴ Orlando et al.,⁸ and Nayak et al.⁷ in the region 190–210 nm, and the values reported by Gillotay and Simon⁴ in the region 212–230 nm.

The temperature dependence of the absorption spectrum has been measured by Hubrich and Stuhl⁶ (160–230 nm) at 298 and 208 K, Gillotay and Simon⁴ (170–230 nm) over the range 210–295 K, Orlando et al.⁸ (190–230 nm) over the range 203–295 K, and Nayak et al.⁷ (160–210 nm) over the range at 223–333 K. A decrease of the absorption cross sections with decreasing temperature was observed by Gillotay and Simon⁴ and Nayak et al.⁷ over the wavelength range 160–230 nm and by Orlando et al.⁸ between 190 and 200 nm. An irregular temperature behavior was reported by Orlando et al.⁸ for the range 215–230 nm where the absorption spectrum at various temperatures cross. The absorption cross sections and temperature dependence have been parameterized using several different empirical functional forms. Gillotay and Simon⁴ used the polynomial expansion:

$$\log_{10} \sigma(\lambda, T) = \sum A_n \lambda^n + (T-273) \times \sum B_n \lambda^n$$

and reported calculated cross section values for T = 210, 230, 250, 270, and 295 K. The A_n and B_n parameters, valid for the temperature range 210–300 K and wavelength range 172–230 nm, are given below.

A ₀ = -328.092008	B ₀ = 4.289533 × 10 ⁻¹
A ₁ = 6.342799	B ₁ = -9.042817 × 10 ⁻³
A ₂ = -4.810362 × 10 ⁻²	B ₂ = 7.018009 × 10 ⁻⁵
A ₃ = 1.611991 × 10 ⁻⁴	B ₃ = -2.389065 × 10 ⁻⁷
A ₄ = -2.042613 × 10 ⁻⁷	B ₄ = 3.039799 × 10 ⁻¹⁰

Nayak et al.⁷ used the expression:

$$\log_{10} (\sigma_T) = \sum C_n (\lambda - 160)^n$$

and reported coefficients for 223, 233, 253, 273, 295, 313, and 333 K and the wavelength range 160–210 nm. The reported C_n parameters are given below.

	223 K	273 K	295 K	333 K
C ₀	-18.2361	-18.2441	-18.2406	-18.1777
C ₁	-1.26669 × 10 ⁻²	-7.37889 × 10 ⁻³	-6.48269 × 10 ⁻³	-2.39647 × 10 ⁻²
C ₂	-2.32945 × 10 ⁻³	-2.66537 × 10 ⁻³	-2.80923 × 10 ⁻³	-7.23910 × 10 ⁻⁴
C ₃	2.81933 × 10 ⁻⁵	4.19193 × 10 ⁻⁵	5.01979 × 10 ⁻⁵	-1.08049 × 10 ⁻⁵
C ₄	-1.37963 × 10 ⁻⁷	-2.88472 × 10 ⁻⁷	-3.96860 × 10 ⁻⁷	1.37618 × 10 ⁻⁷

Orlando et al.⁸ used the expression:

$$\ln \sigma(\lambda, T) = \sum (\sum a_{ij} (T-245.4)^{j-1}) (\lambda-206.214)^{i-1}, \quad i = 1-4, j = 1-3$$

for the temperature range 203–295 K and wavelength range 190–230 nm. The coefficients are given below.

$$\begin{array}{lll} a_{11} = -4.973 \times 10^1 & a_{12} = 9.077 \times 10^{-3} & a_{13} = -4.651 \times 10^{-5} \\ a_{21} = -2.175 \times 10^{-1} & a_{22} = 4.712 \times 10^{-4} & a_{23} = -1.005 \times 10^{-5} \\ a_{31} = 4.133 \times 10^{-4} & a_{32} = -6.432 \times 10^{-5} & a_{33} = 1.141 \times 10^{-6} \\ a_{41} = 7.145 \times 10^{-5} & a_{42} = -5.396 \times 10^{-6} & a_{43} = 1.187 \times 10^{-7} \end{array}$$

Vatsa and Volpp⁹ and Doucet et al. have reported cross section data at and near the Lyman- α wavelength (121.567 nm), respectively. The cross sections at 121.567 nm from these studies are in good agreement. The direct measurement from the Vatsa and Volpp study of $3.1 \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$ is recommended with an uncertainty factor of 1.1 (2σ).

Photolysis Quantum Yield and Product Studies: Quantum yields for Cl ($^2P_{3/2}$) and Cl* ($^2P_{1/2}$) atom formation in the photolysis of CH₃CF₂Cl at 193.3 nm have been measured by Brownsword et al.² to be $\Phi(\text{Cl} + \text{Cl}^*) = 0.90 \pm 0.17$ with $\Phi(\text{Cl}) = 0.65 \pm 0.12$ and $\Phi(\text{Cl}^*) = 0.25 \pm 0.05$. Brownsword et al.¹ reported the quantum yields for H atom formation in the photolysis at 121.6 and 193.3 nm to be 0.53 ± 0.12 and 0.06 ± 0.02 , respectively.

F55. CH₂ClCHO (chloroacetaldehyde)[Back to Index](#)

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of chloroacetaldehyde, CH₂ClCHO, has been measured at room temperature by Lucazeau and Sandorfy² (118–182 nm) and Libuda¹ (235–360 nm). The absorption band centered at ~290 nm has prominent diffuse band structure at wavelengths >280 nm. The recommended absorption cross sections in Table 4F-55 are the average absorption cross sections over 1 nm intervals of the spectrum reported by Libuda¹ (0.6 nm resolution).

Photolysis Quantum Yield and Product Studies: No recommendation.

F56. CHCl₂CHO (dichloroacetaldehyde)[Back to Index](#)

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of dichloroacetaldehyde, CHCl_2CHO , has been measured at room temperature by Lucazeau and Sandorfy² (118–182 nm) and Libuda¹ (253–360 nm), who report an absorption band with weak structure around the maximum at ~300 nm. The recommended absorption cross sections in Table 4F-56 are averages over 1 nm intervals of the spectrum reported by Libuda¹ (0.6 nm resolution).

Photolysis Quantum Yield and Product Studies: No recommendation.

F57. CF_2ClCHO (difluorochloroacetaldehyde)

[Back to Index](#)

$\text{CF}_2\text{ClCHO} + h\nu \rightarrow \text{Products}$

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of difluorochloroacetaldehyde, CF_2ClCHO , has been measured at room temperature by Libuda¹ (235–355 nm) and Rattigan et al.² (235–370 nm). The spectrum displays an absorption band over the wavelength range of the measurements with a maximum at 300 nm. The room temperature cross section data are in good agreement, within 3-10% around the peak, with the data from Rattigan et al.² being systematically greater than those of Libuda.¹ At wavelengths away from the peak the data from Rattigan et al.² are also greater, by 25% at 340 nm and 15 to 300% between 265 and 235 nm.

Rattigan et al.² also reported the temperature dependence of the absorption spectrum over the range 245–298 K. The cross sections increase near the peak and decrease in the long wavelength wing with decreasing temperature. Rattigan et al.² fit the measured temperature dependence with the empirical expression:

$$\ln \sigma(\lambda, T) = \ln \sigma(\lambda, 298 \text{ K}) + B(\lambda)(T-298)$$

The recommended room temperature absorption cross sections in Table 4F-57 are the mean values of the data from Libuda¹ (using 1 nm averages of spectra recorded with 0.6 nm resolution) and Rattigan et al.² (5 nm averages of spectra recorded with 0.6 nm resolution) in the region 235–350 nm and the data from Rattigan et al.² in the region 355–370 nm. The temperature coefficients are taken from Rattigan et al.²

Photolysis Quantum Yield and Product Studies: No recommendation.

F58. CFCl₂CHO (fluorodichloroacetaldehyde)

[Back to Index](#)

CFCl₂CHO + hν → Products

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of fluorodichloroacetaldehyde, CFCl₂CHO, has been measured at room temperature by Libuda¹ (235–360 nm) and Rattigan et al.² (235–370 nm). Over this wavelength range there is an absorption band with a maximum near 296 nm. The cross section data from Libuda¹ are greater by 10-30% than the data from Rattigan et al.² over the entire absorption band (except for a few points in the wings).

Rattigan et al.² also reported the temperature dependence of the absorption spectrum over the temperature range 253–298 K. The cross sections increase near the peak and decrease in the long wavelength wing with decreasing temperature. Rattigan et al.² fit the measured temperature dependence with the empirical expression:

$$\ln \sigma(\lambda, T) = \ln \sigma(\lambda, 298 \text{ K}) + B(\lambda)(T-298)$$

The recommended room temperature absorption cross sections in Table 4F-58 are the mean values of the data from Libuda¹ (using 1 nm averages of spectra recorded with 0.6 nm resolution) and Rattigan et al.² (5 nm averages of spectra recorded with 0.6 nm resolution) in the region 235–355 nm and the data from Rattigan et al.² in the region 360–370 nm. The temperature coefficients are taken from Rattigan et al.²

Photolysis Quantum Yield and Product Studies: No recommendation.

	→ CCl ₃ H + CO	22.6 kJ mol ⁻¹	5300 nm	(4)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The absorption spectrum of trichloroacetaldehyde (chloral), CCl₃CHO, has been measured at room temperature by Lucazeau and Sandorfy ³ (118–182 and 250–357 nm), Libuda² (235–350 nm), Rattigan et al.^{4,5} (200–360 nm), Gillotay et al.¹ (166–348 nm), and Talukdar et al.⁶ (200–344 nm). Overlapping absorption bands were observed with a maximum near 290 nm and a strong band peaking below 180 nm. Except for the data of Lucazeau and Sandorfy,³ the results for the 290 nm absorption band are in reasonable agreement with a 20% range in cross section values at 290 nm. Gillotay et al.¹ report the largest cross section values and Libuda² the smallest. The data sets from Rattigan et al.⁴ and Talukdar et al.⁶ agree to better than 10% around the absorption maximum. At longer wavelengths, the data sets from Rattigan et al.⁴ and Talukdar et al.⁶ are nearly identical. The cross sections from Gillotay et al.¹ are appreciably higher at the longer wavelengths and there is no explanation for this discrepancy. The temperature dependence of the absorption spectrum has been measured by Rattigan et al.^{4,5} (243–296 K), Gillotay et al.¹ (210–295 K), and Talukdar et al.⁶ (240–360 K). These studies are in agreement and found that the absorption cross sections decrease with decreasing temperature below ~260 nm and above ~290 nm. Rattigan et al.⁴ and Talukdar et al.⁶ parameterized the temperature dependence using the empirical expression:

$$\ln \sigma(\lambda, T) = \ln \sigma(\lambda, 298 \text{ K}) + B(\lambda)(T-298)$$

The recommended absorption cross sections and B(λ) temperature coefficients in Table 4F-59 are taken from Talukdar et al.⁶.

Photolysis Quantum Yield and Product Studies: Quantum yields for the production of H, O(³P), and Cl atoms in the photolysis of CCl₃CHO at 193, 248, and 308 nm have been measured by Talukdar et al.⁶ The yields of H and O atoms were found to be small or below the detection limit, Φ(O(³P)) <0.02 and <0.01 at 248 and 308

nm, respectively, and $\Phi(\text{H}) = 0.04 \pm 0.005$, <0.01 , and <0.002 at 193, 248, and 308 nm, respectively. Cl atoms were found to be the primary photolysis product at 308 nm with $\Phi(\text{Cl}) = 1.3 \pm 0.3$.

F60. CH₃C(O)Cl (acetyl chloride)[Back to Index](#)

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of acetyl chloride, CH₃C(O)Cl, has been measured at room temperature by Libuda¹ (233–300 nm) and Maricq² (190–341 nm). In this wavelength range the spectrum has two overlapping continuous absorption bands, one centered near 240 nm and a stronger band peaking below 190 nm. Both studies report a peak cross section for the 240 nm band of $\sim 1.16 \times 10^{-19} \text{ cm}^2 \text{ molecule}^{-1}$. However, the wavelength dependence of the 240 nm band is significantly different in the two studies. Libuda¹ report a narrower band with a peak shifted to longer wavelength compared to that of Maricq.² At wavelengths >280 nm the cross section data reported by Maricq² is very noisy making any comparisons difficult. The recommended absorption cross sections in Table 4F-60 are 1 nm averages of data from Maricq² (0.5 nm resolution) for the region 191–292 nm and 1 nm averages of the data from Libuda¹ (0.6 nm resolution) for the region 293–302 nm.

Photolysis Quantum Yield and Product Studies: No recommendation.

F61. CH₂ClC(O)Cl (chloroacetyl chloride)[Back to Index](#)

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of chloroacetyl chloride, $\text{CH}_2\text{ClC(O)Cl}$, has been measured at room temperature and 234–342 nm by Libuda.¹ The spectrum has an absorption band with the maximum around 248 nm. Above 315 nm the data shows a somewhat irregular behavior and is considered unreliable. Therefore, the recommended absorption cross sections in Table 4F-61 are the 1 nm averages of the data from Libuda¹ (0.6 nm resolution) excluding this region.

Photolysis Quantum Yield and Product Studies: No recommendation.

F62. $\text{CHCl}_2\text{C(O)Cl}$ (dichloroacetyl chloride)

[Back to Index](#)

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of dichloroacetyl chloride, $\text{CHCl}_2\text{C(O)Cl}$, has been measured at room temperature by Libuda¹ (235–338 nm) and Villenave et al.² (200–300 nm). The spectrum has an absorption band with the maximum around 258 nm. The reported cross sections are in very good agreement between 242 and 300 nm with the Villenave et al.² cross sections being systematically smaller by 1–10%. At shorter wavelengths the absorption cross sections reported by Libuda¹ are smaller by up to ~25% at 235 nm. Villenave et al.² observed a minimum near 232 nm and increasing cross sections between 230 and 220 nm. At the longer wavelengths the absorption spectrum reported by Libuda¹ is irregular at wavelengths >316 nm. The recommended absorption cross sections in Table 4F-62 are from Villenave et al.²

Photolysis Quantum Yield and Product Studies: No recommendation.

F63. CCl₃C(O)Cl (trichloroacetyl chloride)

[Back to Index](#)

CCl₃C(O)Cl + hν → Products

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of trichloroacetyl chloride, CCl₃C(O)Cl, has been measured at room temperature by Libuda² (235–342 nm), Villenave et al.³ (220–290 nm), and Gillotay et al.¹ (166–338 nm). The absorption spectrum has two overlapping bands with a peak near 256 nm and a stronger band at shorter wavelengths with a peak at ~176 nm. The spectra reported by Gillotay et al.¹ and Villenave et al.³ are in good agreement. Although the absolute absorption cross sections are similar, the absorption spectrum reported by Libuda² has a significantly different wavelength dependence than reported in the other studies. Although the cross section data from Villenave et al.³ and Gillotay et al.¹ are in good agreement, the recommended absorption cross sections in Table 4F-63 are from Gillotay et al.¹ (0.015 nm resolution) and are averages over the 500 cm⁻¹ and 5 nm intervals generally used in stratospheric photodissociation calculations.

The temperature dependence of the absorption spectrum has been measured by Gillotay et al.¹ over the temperature range 210–295 K. They report an increase in absorption cross section with increasing temperature at all wavelengths.

Photolysis Quantum Yield and Product Studies: No recommendation.

F64. CF₃C(O)Cl (trifluoroacetyl chloride)[Back to Index](#)

(Recommendation: 06-2, Note: 15-10, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of trifluoroacetyl chloride, CF₃C(O)Cl, has been measured at room temperature by Maricq and Szente² (190–342 nm), Rattigan et al.⁴ (220–330 nm), Meller and Moortgat³ (200–329 nm), and Malanca et al.¹ (200–325 nm). The UV absorption spectrum has a band between 215 and 330 nm with a maximum around 255 nm and the shoulder of a stronger band apparent between 200 and 215 nm. The cross section data from the Rattigan et al.,⁴ Meller and Moortgat,³ and Malanca et al.¹ studies are in agreement for wavelengths >240 nm, with the agreement better than 5% between 240 and 315 nm. The Meller and Moortgat³ cross sections are greater than those of Rattigan et al.⁴ and Malanca et al.¹ by ~65% near the absorption minimum at 215 nm. Maricq and Szente² report a very noisy spectrum with an absorption maximum of $(4.6 \pm 0.7) \times 10^{-20}$ cm² molecule⁻¹ at ~255 nm compared to 6.8×10^{-20} cm² molecule⁻¹ by Rattigan et al.⁴ and Malanca et al.¹ and 6.7×10^{-20} cm² molecule⁻¹ by Meller and Moortgat.³

The temperature dependence of the absorption spectrum has been measured by Rattigan et al.⁴ (233, 253 and 296 K), Meller and Moortgat³ (223, 248, 273 and 298 K), and Malanca et al.¹ (253 and 300 K). These studies show a decrease of the absorption cross sections with decreasing temperature in the wavelength regions below ~215 nm and above 255 nm. For the region between 215 and 255 nm, a very slight decrease in absorption cross

section with decreasing temperature was observed in these studies. The recommended absorption cross sections in Table 4E-64 are taken from Malanca et al.¹

Photolysis Quantum Yield and Product Studies: Maricq and Szenté² photolysed CF₃C(O)Cl at 193 and 248 nm in O₂/N₂/C₂H₆ mixtures and measured the formation of the products CF₃O₂, HCl, and CO. They report $\Phi_2 + \Phi_3 = 1.01 \pm 0.11$ at 193 nm and $\Phi_2 + \Phi_3 = 0.92 \pm 0.08$ at 248 nm where channel 2 was determined to be the major dissociation pathway at both wavelengths. Meller and Moortgat³ photolysed CF₃C(O)Cl at 254 nm in N₂ and air/C₂H₆ mixtures over the pressure range 100–760 Torr and measured the formation of the stable end-products CF₃Cl, C₂F₆, Cl₂ and CO. They report the quantum yield for the disappearance of CF₃C(O)Cl to be $\Phi_1 + \Phi_2 = 0.95 \pm 0.05$. Weibel et al.⁵ photolysed CF₃C(O)Cl at 254 and 280 nm in N₂ and air/C₂H₆ mixtures in the pressure range 100–600 Torr and measured the formation of the products CF₃Cl, C₂F₆, and CO. A quantum yield for the decomposition of CF₃C(O)Cl = $\Phi[\text{CF}_3\text{Cl} + 2\text{C}_2\text{F}_6] = 0.98 \pm 0.13$, $\Phi_1 + \Phi_2 = 0.95 \pm 0.05$ was obtained. The quantum yields measured by Meller and Moortgat³ and Weibel et al.⁵ were independent of total pressure. There are no quantum yield data in the atmospherically important wavelength range >290 nm.

Table 4E-64. Recommended Absorption Cross Sections of CF₃C(O)Cl at 300 and 253 K

F65. CH₂=CHCl (vinyl chloride)

[Back to Index](#)

(Recommendation: 19-5, Note: 19-5, Evaluated: 19-5)

Absorption Cross Sections: UV absorption cross sections of CH₂=CHCl (vinyl chloride) have been measured at room temperature, 298 K, by Sood and Watanabe⁴ (164–200.1 nm), Berry¹ (140–220 nm), Locht et al.³ (82.65–247.97 nm), and Limão-Vieira et al.² (115–340 nm). The spectra reported by Limão-Vieira et al. and Sood and Watanabe are in good agreement, to within 20%, or better, between 185 and 200 nm. The spectrum reported by Locht et al. is ~30% less over the same wavelength range and shows significant scatter at longer wavelengths. The absorption cross sections reported graphically by Berry are significantly greater than in the other studies and not considered further. The recommended UV absorption cross sections given in Table 4F-65 at 1 nm intervals between 185 and 218 nm are taken from Limão-Vieira et al. Higher-resolution data are available from their study. The recommended estimated uncertainty factors (F(λ), 2σ) are assigned as F(λ) = 1.20 + 1 × 10⁻²⁰/σ(λ).

The VUV absorption spectrum of CH₂=CHCl has been reported by Limão-Vieira et al.² (115–340 nm, 298 K) and Locht et al.³ (82.65–247.97 nm, 298 K). The Lyman-α (121.567 nm) cross section derived from these studies are 5.1 × 10⁻¹⁷ and 4.1 × 10⁻¹⁷ cm² molecule⁻¹, respectively. An average value of 4.6 × 10⁻¹⁷ cm² molecule⁻¹ with an uncertainty factor (2σ) of 1.2 is recommended for the Lyman-α cross section.

Photolysis Quantum Yield and Product Studies: No recommendation.

F66. $CHCl=CCl_2$ (trichloroethene)

[Back to Index](#)

(Recommendation: 19-5, Note: 19-5, Evaluated: 19-5)

Absorption Cross Sections: UV absorption cross sections of $CHCl=CCl_2$ (trichloroethene) have been measured at room temperature by Berry¹ (298 K, 139–244 nm, presented graphically) and Robbins² (295 K, 174–270 nm, 0.07 nm resolution). The recommendation is taken from Robbins and given in Table 4F-66. The recommended estimated uncertainty factors ($F(\lambda)$, 2σ) are assigned as $F(\lambda) = 1.20 + 5 \times 10^{-22}/\sigma(\lambda)$.

Photolysis Quantum Yield and Product Studies: No recommendation.

F67. $CCl_2=CCl_2$ (tetrachloroethene)

[Back to Index](#)

(Recommendation: 19-5, Note: 19-5, Evaluated: 19-5)

Absorption Cross Sections: UV absorption cross sections of $CCl_2=CCl_2$ (tetrachloroethene) have been measured at room temperature, 298 K, by Berry¹ (142–254 nm, presented graphically) and Eden et al.² (115–328 nm, 0.075 nm resolution). The agreement between these studies is reasonably good, except at the longest wavelengths of the Berry study. The recommended UV cross sections over the wavelength range 184–270 nm were taken from Eden et al. and are given in Table 4F-67 at 2 nm intervals. The recommended estimated uncertainty factors ($F(\lambda)$, 2σ) are assigned as $F(\lambda) = 1.25 + 5 \times 10^{-21}/\sigma(\lambda)$.

The recommended Lyman- α (121.567 nm) absorption cross section of $4.47 \times 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$ was derived from the VUV spectrum reported in the Eden et al. study. An uncertainty factor (2σ) of 1.2 is recommended.

Photolysis Quantum Yield and Product Studies: No recommendation.

F68. $\text{CF}_3\text{CF}_2\text{CHCl}_2$ (1,1,1,2,2-pentafluoro-3,3-dichloropropane, HCFC-225ca)

[Back to Index](#)

$\text{CF}_3\text{CF}_2\text{CHCl}_2$ (HCFC-225ca) + $h\nu \rightarrow$ Products

(1)

(Recommendation: 02-25, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of 1,1,1,2,2-pentafluoro-3,3-dichloropropane (HCFC-225ca), $\text{CF}_3\text{CF}_2\text{CHCl}_2$, has been measured in the gas and liquid phase at 298 K by Braun et al.¹ (160–250 nm). The recommended absorption cross sections in Table 4F-68 are taken from this work. Braun et al.¹ give an expression that can be used to calculate the gas-phase absorption cross sections over the wavelength range 170–270 nm:

$$\log_{10} \varepsilon = \sum a_n (\lambda - 160)^n$$

$$\begin{array}{ll} a_0 = 1.425 & a_1 = 4.542 \times 10^{-2} \\ a_2 = -2.036 \times 10^{-3} & a_3 = 1.042 \times 10^{-5} \end{array}$$

where the absorption coefficients ε are in units of $(\text{atm}, 298 \text{ K})^{-1} \text{ cm}^{-1}$ ($\sigma = 4.06 \times 10^{-20} \varepsilon$).

Photolysis Quantum Yield and Product Studies: No recommendation.

F70. CH₃C(O)CH₂Cl (chloroacetone)

[Back to Index](#)

CH₃C(O)CH₂Cl + hν → Products

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption cross sections of chloroacetone, CH₃C(O)CH₂Cl, have been measured over the temperature range 243–296 K between 210 and 370 nm by Burkholder et al.¹ using diode array spectroscopy (~0.6 nm resolution). The spectrum has two absorption bands, a strong band with the maximum at ~224 nm (3.35×10^{-19} cm² molecule⁻¹ at 296 K) and a weaker broader band with the maximum at ~292 nm (1.02×10^{-19} cm² molecule⁻¹ at 296 K). A systematic decrease in the absorption cross section with decreasing temperature was observed at wavelengths >290 nm. A temperature dependence of the absorption cross sections was also reported for the short wavelength absorption band. The reported values at 253 K are larger than those at 273 K below ~240 nm and even larger than those at 296 K below ~230 nm. The recommended absorption cross sections in Table 4F-70 are taken from Burkholder et al.¹

Photolysis Quantum Yield and Product Studies: Photodissociation quantum yields were measured by Burkholder et al.¹ to be 0.5 ± 0.08 at 308 nm and 351 nm. At both wavelengths, the yields of CO and CO₂ were 0.50 and ~0.25, respectively. The yield of HCOOH and HCl were reported to be 0.25 and 0.5, respectively, at both photolysis wavelengths.

(1)

(Recommendation: 15-10; Note: 15-10; Evaluated: 15-10)

Absorption Cross Sections: The UV absorption cross sections of (E)-1,2-dichlorohexafluorocyclobutane, 1,2-c-C₄Cl₂F₆(E), have been measured by Papadimitriou et al.¹ (184.95–230 nm) at temperatures between 214 and 296 K. UV absorption spectra of (E)- and (Z)- isomeric mixtures (0.94:0.06 and 0.475:0.525) were measured experimentally and individual isomer spectra were determined using the measured sample mixing ratios. Over the 185–230 nm wavelength range the spectrum is continuous with a broad peak near 195 nm. The absorption

cross sections decrease nearly exponentially at wavelengths greater than ~200 nm. The (*E*)- isomer was observed to be a stronger absorber than the (*Z*)- isomer over this wavelength range. The 296 K absorption cross section uncertainty was estimated to be ~3% (2 σ) at all wavelengths included in their study.

Papadimitriou et al. measured the spectrum temperature dependence over the range 214–296 K. They observed a systematic decrease in absorption cross section with decreasing temperature at all wavelengths included in their study. The absorption spectrum was parameterized using the empirical formula:

$$\log_{10}(\sigma(\lambda, T)) = \sum_i A_i(\lambda - 200)^i + (296 - T) \sum_i B_i(\lambda - 200)^i$$

and the optimized parameters are given in Table 4F-71. The parameterization reproduces the absorption spectrum to within the estimated measurement precision and is valid over the 190–220 nm wavelength range and 210–296 K temperature range.

Table 4F-71. Recommended (*E*)-1,2-*c*-C₄Cl₂F₆ Absorption Spectrum, $\sigma(\lambda, T)$, Parameterization

Photolysis Quantum Yield and Product Studies: Quantum yields for the production of Cl atoms and *c*-C₄F₆ in the photolysis of 1,2-*c*-C₄Cl₂F₆(*E*) at 193 nm were measured by Papadimitriou et al.¹ A value of $\Phi(\text{Cl}) = 1.9 \pm 0.27$ was determined for a 0.475:0.525 isomeric mixture (i.e., quantum yields for the individual isomers were not determined). A value of $\Phi(\text{Cl}) = 2$ is recommended. The *c*-C₄F₆ product yield in the photolysis of 1,2-*c*-C₄Cl₂F₆(*E*) was found to be 0.7 ± 0.1 .

(1)

(Recommendation: 15-10; Note: 15-10; Evaluated: 15-10)

Absorption Cross Sections: The UV absorption cross sections of (*Z*)-1,2-dichlorohexafluorocyclobutane, 1,2-*c*-C₄Cl₂F₆(*Z*), have been measured by Papadimitriou et al.¹ (184.95–230 nm) at temperatures between 214 and 296 K. UV absorption spectra of (*E*)- and (*Z*)- isomeric mixtures (0.94:0.06 and 0.475:0.525) were measured experimentally and individual isomer spectra were determined using the measured mixing ratios. The (*Z*)- isomer was found to be a significantly weaker absorber than the (*E*)- isomer over this wavelength range. The uncertainty in the (*Z*)- isomer 296 K absorption cross sections were estimated to be significantly greater than for the (*E*)- isomer, e.g. ~25% (2 σ) at 210 nm.

Papadimitriou et al. measured the spectrum temperature dependence over the range 214–296 K. They observed a systematic decrease in absorption cross section with decreasing temperature at all wavelengths included in their study. The absorption spectrum was parameterized using the empirical formula:

$$\log_{10}(\sigma(\lambda, T)) = \sum_i A_i(\lambda - 200)^i + (296 - T) \sum_i B_i(\lambda - 200)^i$$

and the optimized parameters are given in Table 4F-72. The parameterization reproduces the absorption spectrum to within the estimated measurement precision and is valid over the 190–220 nm wavelength range and 210–296 K temperature range.

Table 4F-72. Recommended (Z)-1,2-*c*-C₄Cl₂F₆ Absorption Spectrum, $\sigma(\lambda, T)$, Parameterization

SECTION 4G. BrO_x PHOTOCHEMISTRY

G1. Br₂ (molecular bromine)

[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV/vis absorption spectrum of Br₂, molecular bromine, has been extensively studied as summarized in Table 4G-1-1.

Table 4G-1-1. Summary of Br₂ Absorption Cross Section Studies

Study	Year	Temperature (K)	Wavelength Range (nm)
Ribaud ¹⁴	1919	289, 593, 893	356–608
Gray and Style ³	1930	294	240–579
Acton et al. ¹	1936	293, 400, 531, 657, 767, 906	327.4–571.7

Hubinger and Nee ⁶	1995	295	190–600
Tellinghuisen ¹⁷	2008	295	190–300

The Br₂ spectrum exhibits an absorption band between 190 and 300 nm with a maximum near 223 nm and another stronger band between 300 and 600 nm, which is composed of three overlapping bands with maxima at ~412, 480, and 549 nm. The reported absorption cross sections are in very good agreement in the region of the UV-visible absorption band. Discrepancies are observed at wavelengths >550 nm, where the data of MacMillan¹¹ and Hemenway et al.⁵ are as much as 60% and 100% lower, respectively, than the values measured in the other studies. Large discrepancies arise in the region of the absorption minimum between 230 and 340 nm due to a pressure dependent absorption component of Br₂ vapor, possibly due to a Br₂-Br₂ dimer absorption. A detailed discussion of the available absorption data for Br₂ and an evaluation is given by Maric et al.¹⁰ Maric et al. fit the most reliable data, those of Passchier et al.¹² and Wen and Noyes,¹⁸ to a four-band semi-logarithmic distribution function and derived the following expression for the calculation of the Br₂ absorption spectrum over the wavelength region 200–650 nm:

$$\begin{aligned} \sigma(298 \text{ K}) = & 1.06 \times 10^{-20} \times \exp(-52.3[\ln(223.3/\lambda)]^2) \\ & + 6.19 \times 10^{-19} \times \exp(-108.5[\ln(411.9/\lambda)]^2) \\ & + 3.39 \times 10^{-19} \times \exp(-106.8[\ln(480.2/\lambda)]^2) \\ & + 3.78 \times 10^{-20} \times \exp(-112.0[\ln(549.3/\lambda)]^2) \end{aligned}$$

where λ is the wavelength in nm (vacuum) and σ is the absorption cross section in cm² molecule⁻¹. The recommended absorption cross sections calculated using this expression are listed in Table 4G-1-2. The results of Maric et al.¹⁰ have been confirmed, in general, in a subsequent study by Hubinger and Nee,⁶ who reported absorption cross sections for the wavelength range 190–600 nm. The Hubinger and Nee cross sections values that are below 10⁻²¹ cm² molecule⁻¹, i.e., between 260 and 340 nm, differ from the parameterized data of Maric et al.¹⁰ and should be considered as upper limits.

The temperature dependence of the absorption spectrum has been measured by Acton et al.¹ (293–906 K) and Passchier et al.¹² (298–713 K). These studies report a decrease of the cross sections around the absorption maximum, between ~380 and ~500 nm, and an increase in the short and long wavelength tails with increasing temperature.

Photolysis Quantum Yield and Product Studies: Photodissociation of Br₂ leads to the formation of Br atoms in the ground Br(²P_{3/2}) and excited Br*(²P_{1/2}) states. A few studies have been performed to establish the relative quantum yields of (Br + Br) and (Br + Br*) at various photolysis wavelengths. Petersen and Smith¹³ found the

yield of Br* atoms to increase from 0.4 to 0.89 from 444 to 510 nm and decrease at longer wavelengths to a value of ~0.4 at 530 nm. Lindeman and Wiesenfeld⁹ observed the relative quantum yield (Br + Br*) to increase from 0.07 at 434 nm to 0.64 at 482 nm and then to decrease to 0.57 at 511 nm. Haugen et al.⁴ determined the relative quantum yield (Br + Br*) to increase from 0.44 at 445 nm to 0.87 at 500 nm followed by a decrease to 0.40 at 530 nm. Cooper et al.² measured the relative (Br + Br*) yield to be zero in the range 360 to 430 nm and to increase at longer wavelengths to 0.79 at 580 nm; at 260 nm they observed (Br + Br*) to be dominant. Jee et al.^{7,8} measured the relative yield of the photodissociation channel into (Br + Br*) at 234 nm to be unity and at 265 nm to be 0.96. Zaraga et al.¹⁹ calculated the zero pressure predissociation quantum yield from high resolution spectroscopic studies in the banded region (B ³Π(0_u⁺) state) overlapping a continuum at 588 nm to be near unity.

G2. HBr (hydrogen bromide)

[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of HBr, hydrogen bromide, at wavelengths >180 nm consists of a continuous band with a maximum near 178 nm and monotonically decreasing absorption cross sections that have been measured out to 270 nm. At shorter wavelengths the spectrum shows a large number of strong sharp bands that extend to 105 nm.

The room temperature absorption cross sections of HBr have been measured in a number of studies as outlined in Table 4G-2-1. The absorption cross sections near the maximum of the absorption band reported by Nee et al.⁷ and Huebert and Martin⁶ are in good agreement, 2.4×10^{-18} and 2.7×10^{-18} cm² molecule⁻¹, respectively. The values reported by Romand¹² and Roxlo and Mandl¹³ are substantially lower, 2×10^{-18} and 1.4×10^{-18} cm² molecule⁻¹, respectively. The cross section at 193 nm reported by Vaghjiani¹⁴ and Barone et al.¹ are consistent with the absorption spectra reported by Nee et al.⁷ and Huebert and Martin.⁶ The cross sections at 184.9 nm measured by Ravishankara et al.¹⁰ and Barone et al.¹ fall between those reported by Nee et al.⁷ and Huebert and Martin.⁶ The cross section at 184.9 nm measured by Okabe⁸ lies between those of Goodeve and Taylor⁵ and Romand.¹² The recommended values in Table 4G-2-2 were derived as follows: the spectra of Goodeve and Taylor,⁵ Romand,¹² Huebert and Martin,⁶ and Nee et al.⁷ have been scaled to 2.21×10^{-18} cm² molecule⁻¹ at 184.9 nm, which is the mean of the values reported by Okabe,⁸ Ravishankara et al.,¹⁰ and Barone et al.¹; the scaled spectra have been averaged, the recommended cross sections for the range 152–168 nm are those of Romand¹² and Nee et al.,⁷ for the range 170–180 nm those of Romand,¹² Huebert and Martin,⁶ and Nee et al.⁷ and for the range 182–230 nm those of Goodeve and Taylor,⁵ Romand,¹² Huebert and Martin,⁶ and Nee et al.⁷

Table 4G-2-1. Summary of HBr UV Absorption Cross Section Studies

Study	Year	Temperature (K)	Wavelength Range (nm)
Goodeve and Taylor ⁵	1935	298	182–286
Romand ¹²	1949	298	139–228
Huebert and Martin ⁶	1968	297	170–230
Bridges and White ³	1973	298	214
Okabe ⁸	1977	296	240–270
Ravishankara et al. ¹⁰	1979	298	184.9
Roxlo and Mandl ¹³	1980	298	170–230
Okabe ⁹	1983	296	184.9
Brion et al. ⁴	1985	298	30–177
Nee et al. ⁷	1986	298	105–238
Vaghjiani ¹⁴	1993	296	193
Barone et al. ¹	1994	298	184.9, 193.0

Photolysis Quantum Yield and Product Studies: The branching fraction for the formation of excited Br*(²P_{1/2}) atoms was determined by Regan et al.¹¹ in the wavelength range 201–253 nm to vary between 0.15 and 0.23. Baumfalk et al.² obtained a Br* branching fraction, Br*(²P_{1/2})/(Total Br), of 0.20 ± 0.03 at 243 nm and 0.18 ± 0.03 at 193 nm.

Table 4G-2-2. Recommended Absorption Cross Sections of HBr at 298 K

λ (nm)	$10^{20} \sigma$ (cm ²)	λ (nm)	$10^{20} \sigma$ (cm ²)	λ (nm)	$10^{20} \sigma$ (cm ²)	λ (nm)	$10^{20} \sigma$ (cm ²)

G3. BrO (bromine monoxide radical)

[Back to Index](#)

(Recommendation: 06-2, Note: 25-1, Evaluated: 10-6)

Absorption Cross Sections: The BrO (bromine monoxide) radical has a UV absorption spectrum in the 290–380 nm range, with vibrational band structure, which is attributed to the $A^2\Pi_{3/2} \leftarrow X^2\Pi_{3/2}$ transition. The spectrum measured by Wilmouth et al.¹² (0.5 nm) is shown in Figure 4G-3-1 and laboratory measurements are summarized in Table 4G-3-1. The absorption spectrum has been measured and cross sections determined for several absorption peaks in the studies listed in Table 4G-3-1, e.g. for the strongest (7,0) band at 338.5 nm and the (11,0) and (12,0) bands at 320.8 nm and 317.3 nm.

Table 4G-3-1. Summary of BrO Absorption Cross Section Studies

Study	Year	Temperature (K)	Wavelength Range (nm)	Resolution (nm)
Clyne and Cruse ²	1970	293	338.3	0.15
Basco and Dogra ¹	1971	298	320.8, 338.3	not given
Cox et al. ³	1982	298	296–370	0.22
Wahner et al. ¹⁰	1988	228, 243, 298	312–380	0.4
Sander and Friedl ⁹	1989	220, 298	338.5	0.06–1.25
Orlando et al. ⁸	1991	298	338.5	0.4
Laszlo et al. ⁷	1997	295	338.5	0.6
Gilles et al. ⁶	1997	204, 222, 237, 252, 273, 298, 329, 369	338.5	0.5
Wheeler et al. ¹¹	1998	298	338, 317	4 cm ⁻¹
Wilmouth et al. ¹²	1999	298	317–388	1.0 cm ⁻¹
Wilmouth et al. ¹²	1999	228, 298	286–386	10 cm ⁻¹
Fleischmann et al. ⁴ and Fleischmann et al. ⁵	2003 2004	203, 223, 243, 273, 298	300–385	~4 cm ⁻¹

The cross sections are both temperature and resolution dependent, i.e., the peaks of the vibrational bands become greater and the bands sharper with decreasing temperature and at higher resolution. Wilmouth et al.¹² used their absorption spectrum, recorded at 10 cm⁻¹ resolution, in a combined analysis of the results from Cox et al.,³ Wahner et al.,¹⁰ Orlando et al.,⁸ Laszlo et al.,⁷ and Gilles et al.⁶ at a common resolution of 0.40 nm (details of this procedure are described in Wilmouth et al.¹²). The vibrational band peak absorption cross sections at 298 ± 2 and 228 ± 2 K obtained in their analysis are listed in Table 4G-3-2. Absorption cross sections of the spectrum reported by Wilmouth et al.,¹² averaged over 0.5 nm intervals are listed in Table 4G-3-3.

Absorption cross sections for the rotational peaks of the (7,0) and (12,0) bands were measured at high resolution (1.0 cm⁻¹) by Wilmouth et al.¹² to be 2.17 × 10⁻¹⁷ cm² molecule⁻¹ for the peak of the (7,0) band and 1.38 × 10⁻¹⁷ cm² molecule⁻¹ for the peak of the (12,0) band.

The (7,0) absorption maximum (338 nm) temperature dependence was measured by Gilles et al.⁶ over the range 204–388 K at a resolution of 0.5 nm and given by the expression:

$$\sigma(T)_{338 \text{ nm}} = 3.29 - (5.58 \times 10^{-3}) \times T, \text{ in units of } 10^{-17} \text{ cm}^2 \text{ molecule}^{-1}$$

Photolysis Quantum Yield and Product Studies: Transitions in the A←X system are expected to be dissociative.

G4. OBrO (bromine dioxide)

[Back to Index](#)

(Recommendation: 06-2, Note: 25-1, Evaluated: 10-6)

Absorption Cross Sections: The visible absorption spectrum of OBrO, bromine dioxide, has been measured in the 400–600 nm region at room temperature by Rowley et al.,⁵ Knight et al.,² and Fleischmann et al.,¹ at ~250 K by Miller et al.,³ and at 273, 298, and 338 K by Rattigan et al.⁴ The OBrO spectrum measured by Knight et al. is shown in Figure 4G-4-1. The spectrum has a highly structured absorption band consisting of a progression of doublets with a maximum intensity near 500 nm and a progression of less intense bands between the doublets. The spectrum was assigned to the $C^2A_2 \leftarrow X^2B_1$ electronic transition by Miller et al.³ who combined *ab initio* calculations of the lowest doublet electronic states of OBrO with Franck-Condon simulations. Fleischmann et al. have provided a detailed vibrational analysis of the OBrO spectrum. Knight et al.² reported absorption cross section data. The peak positions and cross sections for the vibrational progressions $(n,0,0) \leftarrow (0,0,0)$ and $(n,1,0) \leftarrow (0,0,0)$ in Table 4G-4-1 are taken from Knight et al.² Table 4G-4-2 gives the absorption cross section averages over 1 nm intervals of the spectrum reported by Knight et al.² (0.66 nm resolution).

Photolysis Quantum Yield and Product Studies: No quantum yields are available but theoretical calculations by Vetter et al.⁶ indicate that photodissociation occurs via the $\text{BrO} + \text{O}(^3\text{P})$ channel because of a large transition dipole moment for the $C^2A_2 \leftarrow X^2B_1$ transition. Photodissociation into $\text{Br} + \text{O}_2$ occurs via the 1^2B_2 state and is less probable.

G5. Br₂O (dibromine monoxide)

[Back to Index](#)

Br ₂ O + hv	→ Br + BrO	128 kJ mol ⁻¹	938 nm	(1)
	→ Br ₂ + O	173 kJ mol ⁻¹	693 nm	(2)
	→ Br + Br + O	366 kJ mol ⁻¹	327 nm	(3)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of Br₂O, dibromine monoxide, has been measured at room temperature by Orlando and Burkholder³ (196–432 nm), Rattigan et al.⁴ (240–515 nm), and Deters et al.² (208–444 nm). The spectrum exhibits a strong narrow band at wavelengths <220 nm with a maximum at 200 nm, a weaker and broader band extending from 250 nm to about 460 nm with a maximum at 313 nm and a shoulder near 350 nm, and two weak bands at 460–580 nm and 580–750 nm with maxima at ~520 nm and ~665

nm. There is good agreement between the various data sets in the wavelength region <380 nm where the data of Orlando and Burkholder³ and Deters et al.² are nearly identical and those of Rattigan et al.⁴ are smaller by ~10% below 250 nm and above 290 nm and smaller by up to ~25% in the region of the absorption minimum near 270 nm. Large discrepancies exist between the data sets at wavelengths >380 nm. The absorption cross sections reported by Orlando and Burkholder³ and Deters et al.² decrease at longer wavelengths to values $\leq 1 \times 10^{-20}$ cm² molecule⁻¹ whereas the values reported by Rattigan et al.⁴ show a decrease between 400 and 470 nm and evidence for another absorption band at longer wavelengths. The cutoff at 440 nm of the absorption spectrum reported by Orlando and Burkholder³ is a result of the assumption that the absorbance of Br₂O is zero at wavelengths >440 nm. The correction procedure used by Rattigan et al.⁴ taking the vibrational structure of the Br₂ spectrum into account resulted in appreciable absorption for Br₂O at wavelengths above 440 nm. The recommended cross sections in Table 4G-5 are the data from Orlando and Burkholder³ at 196 and 200 nm, the mean of the data from Orlando and Burkholder³ and Deters et al.² for the region 210–230 nm, and the mean of the data from Orlando and Burkholder,³ Deters et al.,² and Rattigan et al.⁴ for the region 240–400 nm. No recommendation is given for wavelengths >400 nm.

Photolysis Quantum Yield and Product Studies: By analogy to Cl₂O the predominate photodissociation channel is expected to be Br + BrO. Burkholder¹ measured the BrO yield at 308 nm to be near unity.

G6. HOBr (hypobromous acid)[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of HOBr, hypobromous acid, has been measured by Orlando and Burkholder⁸ (240–404 nm), Deters et al.³ (250–400 nm), Benter et al.² (234–390 nm), Rattigan et al.⁹ (240–510 nm), and Ingham et al.⁵ (260–600 nm). Orlando and Burkholder,⁸ Deters et al.,³ and Benter et al.² observed two absorption bands with maxima near 284 and 351 nm. The reported spectra agree reasonably well in their wavelength dependence with a sharp decrease in cross section at wavelengths greater than 400 nm. In contrast, the cross sections reported by Rattigan et al.⁹ and Ingham et al.⁵ are roughly 50% greater between 300 and 400 nm. In addition, the spectrum reported by Rattigan et al.⁹ has pronounced long wavelength absorption that extends to 520 nm. Ingham et al.⁵ report a similar spectrum to Rattigan et al., but with a more prominent absorption band at long wavelength with a maximum at 457 nm. These two studies are consistent with the observations of Barnes et al.,¹ who showed that laser photolysis of HOBr between 440–600 nm gives rise to OH photofragments. The presence of a weak band beyond 400 nm is attributable to the presence of a forbidden transition from the ground electronic to a triplet state as predicted by the *ab initio* calculations of Francisco et al.⁴ and Minaev.⁷ The differences in the spectral shapes are probably attributable to impurities such as Br₂O and Br₂, and/or the use of different Br₂O cross sections. However, the presence of impurities alone cannot explain the large difference in cross sections at the peak of the absorption bands.

The recommended absorption cross sections in Table 4G-6 are based on the study by Ingham et al.⁵ These authors generated HOBr in situ by laser photolytic production of OH in the presence of Br₂, and determined the HOBr spectrum using a gated diode camera shortly after the pulse, circumventing the problem associated with the presence of the strong absorbing impurity Br₂O, which was present in previous studies. The calibration of the absorption cross sections was made relative to the cross sections of Br₂. No recommendation is given for wavelengths <250 nm where the data are uncertain. On the basis of the level of agreement among the available studies, cross section uncertainty factors (2σ) of 1.25 (250–300 nm), 1.5 (300–400 nm), 3 (400–500 nm), and 10 (>500 nm) are estimated for the wavelength ranges given in parenthesis.

The data presented in Table 4G-6 were computed with the following expression taken from Ingham et al.,⁵ which is based on a combination of three Gaussian functions, one for each absorption band:

$$\sigma(\lambda) = 24.77 \exp \left\{ -109.80 \left[\ln \left(\frac{284.01}{\lambda} \right) \right]^2 \right\} + 12.22 \exp \left\{ -93.63 \left[\ln \left(\frac{350.57}{\lambda} \right) \right]^2 \right\} \\ + 2.283 \exp \left\{ -242.40 \left[\ln \left(\frac{457.38}{\lambda} \right) \right]^2 \right\}$$

where $\sigma(\lambda)$ is in units of 10⁻²⁰ cm² molecule⁻¹ and λ is in nm.

Photolysis Quantum Yield and Product Studies: Benter et al.² measured quantum yields for HOBr photolysis at 261 and 363 nm (near the band peaks). The observed quantum yield for Br formation at 363 nm was greater than 0.95 and a unity quantum yield for the OH + Br product channel is recommended. No evidence for the O + HBr product channel was observed. The laser photofragment study of Barnes et al.¹ claimed that OH was the major photolysis product at wavelengths >400 nm. Lock et al.⁶ found that at 490 and 510 nm OH and Br photofragments are in their respective vibrational and spin-orbit ground states.

G7. BrNO (nitrosyl bromide)[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The absorption spectrum of BrNO, nitrosyl bromide, has been measured at room temperature by Eden et al.¹ (275–550 nm), Houel and van den Bergh³ (200–800 nm), Uthman et al.⁵ (189–300 nm), Hippler et al.² (266 nm), and Maloney and Palmer⁴ (270 nm). The spectrum exhibits four absorption bands between 200 and 800 nm, a strong band between 190 and 290 nm with the maximum at ~213 nm, a weaker band between 290 and 600 nm with the maximum at 338 nm and a shoulder near 420 nm, and a still weaker band between 600 and 800 nm with the maximum at 708 nm. The absorption cross sections from these studies are in good agreement (after correction of an error in Maloney and Palmer⁴). The recommended absorption cross sections in Table 4G-7 are from Uthman et al.⁵ for the region 189–300 nm and the cross sections at 338, 416, and 708 nm reported by Houel and van den Bergh³.

Photolysis Quantum Yield and Product Studies: No recommendation.

G8. cis-BrONO (bromine nitrite)[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of *cis*-BrONO, bromine nitrite, has been measured in the temperature range 228–296 K by Burkholder and Orlando¹ (200–365 nm). The spectrum exhibits a strong absorption band between 200 and 270 nm with a maximum at 228 nm and a broader and weaker band between 270 and 364 nm with a maximum at 316 nm. The shape of the *cis*-BrONO spectrum was independent

of temperature over the 228–296 K range to within the uncertainty of the measurements. The results from Burkholder and Orlando¹ are recommended and listed in Table 4G-8.

Photolysis Quantum Yield and Product Studies: No recommendation.

G9. BrNO₂ (nitryl bromide)

[Back to Index](#)

BrNO ₂ + hv	→ Br + NO ₂	101 kJ mol ⁻¹	1185 nm	(1)
	→ BrO + NO	172 kJ mol ⁻¹	693 nm	(2)
	→ Br + NO + O	407 kJ mol ⁻¹	294 nm	(3)

(Recommendation: 10-6, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: Scheffler et al.² measured the room temperature absorption spectrum of BrNO₂, nitryl bromide, over the wavelength range 185–530 nm. The spectrum consists of several overlapping electronic transitions with a strong band in the actinic region (>200 nm). The recommended absorption cross sections in Table 4G-9 are taken from Scheffler et al.² between 185 and 430 nm while values at $\lambda > 430$ nm were obtained from a log-linear fit of the data reported by Scheffler et al. The BrNO₂ spectrum recorded in the Burkholder and Orlando¹ study of *cis*-BrONO was reported to be in good agreement with the Scheffler et al. spectrum.

Photolysis Quantum Yield and Product Studies: By analogy with ClNO₂, the most likely photolysis products are expected to be Br + NO₂.

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV/vis absorption spectrum of BrONO₂, bromine nitrate, has been measured at room temperature by Spencer and Rowland⁵ (186–390 nm), Burkholder et al.¹ (200–500 nm), and Deters et al.² (210–500 nm). The absorption cross sections reported by Burkholder et al.¹ and Deters et al.² are nearly identical over the range of spectral overlap. The results of Spencer and Rowland⁵ agree to within 10% with those of Burkholder et al.¹ and Deters et al.² except for the region between 315 and 350 nm where the Spencer data are higher by 10 to 20%.

The temperature dependence of the absorption spectrum has been measured by Burkholder et al.¹ (200–500 nm) at 220, 250, and 298 K and Deters et al.² (210–500 nm) at 230 and 298 K. The temperature dependence of the absorption cross sections is in general weak. Burkholder et al.¹ observed decreasing cross sections with decreasing temperature between 200 and 215 nm and between 230 and 500 nm and a slight increase between 215 and 230 nm. The reported ratio $\sigma(220\text{ K})/\sigma(298\text{ K})$ has values of ~0.8 to 1.03 between 200 and 235 nm, a minimum of 0.90 at 260 nm, nearly constant values of ~0.95 between 290 and 370 nm, a minimum of ~0.87 at

430 nm, two maxima of ~0.98 around 445 nm, and decreases to ~0.5 at 500 nm. The measurements of Deters et al.² show a similar behavior of $\sigma(230\text{ K})/\sigma(298\text{ K})$ vs. λ with all values below 1, i.e., a decrease of the cross sections with decreasing temperature is observed over the entire spectrum. Burkholder et al.¹ parameterized the cross section temperature dependence using the expression:

$$\sigma(\lambda, T) = \sigma(\lambda, 296\text{ K}) [1 + A_1(\lambda)(T-296) + A_2(\lambda)(T-296)^2]$$

The recommended absorption cross sections and temperature coefficients in Table 4G-10-1 are taken from Burkholder et al.¹ A cross section uncertainty factor of 1.2 (2σ), independent of wavelength, is assigned, which encompasses the results from all the room temperature studies.

Photolysis Quantum Yield and Product Studies: Photodissociation quantum yields have been measured for photolysis wavelengths between 248 and 355 nm as summarized in Table 4G-10-2. The quantum yields for NO_3 production were measured by Harwood et al.³ to be $\Phi(\text{NO}_3) = 0.28 \pm 0.09$ at 248 nm, 1.01 ± 0.35 at 305 nm and 0.92 ± 0.43 at 352.5 nm. The quantum yields for BrO and Br were also estimated at 248 nm to be $\Phi(\text{BrO}) \approx 0.5$ and $\Phi(\text{Br}) \approx 0.5$. Soller et al.⁴ investigated the production of Br, $\text{O}(^3\text{P})$, and BrO from the photolysis of BrONO_2 in the wavelength range 248–355 nm. The quantum yield for the Br atom are 0.35 ± 0.08 , 0.65 ± 0.14 , $>0.62 \pm 0.11$, and 0.77 ± 0.19 at 248, 266, 308, and 355 nm, respectively. The values for the $\text{O}(^3\text{P})$ atom quantum yields are 0.66 ± 0.15 , 0.18 ± 0.04 , $<0.13 \pm 0.03$, and <0.02 at 248, 266, 308 and 355 nm, respectively. The measured quantum yields for BrO are 0.37 ± 0.12 at 266 nm and 0.23 ± 0.08 at 355 nm. A total quantum yield Φ_{BrONO_2} of unity is recommended for wavelengths >300 nm with $\Phi_{\text{Br}+\text{NO}_3} = 0.85$ and $\Phi_{\text{BrO}+\text{NO}_2} = 0.15$. No recommendation is given for wavelengths <300 nm.

G11. BrCl (bromine chloride)[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of BrCl, bromine chloride, has been measured at room temperature by Gray and Style¹ (240–313 nm and 546 nm), Jost³ (486–548 nm), Seery and Britton⁵ (220–510 nm), Maric et al.⁴ (200–600 nm), Hubinger and Nee² (190–560 nm), and Tellinghuisen⁷ (200–600 nm). The spectrum exhibits an absorption band between 190 and 290 nm with a maximum at 230 nm ($\sigma \approx (6.0\text{--}7.2) \times 10^{-20} \text{ cm}^2 \text{ molecule}^{-1}$) and a stronger band between 290 and 600 nm with the maximum at 375 nm ($\sigma \approx (3.9\text{--}4.1) \times 10^{-19} \text{ cm}^2 \text{ molecule}^{-1}$) and a shoulder near 470 nm. There is good agreement between the cross section results of the studies except for the values at 289 and 297 nm reported by Gray and Style,¹ which are smaller by a factor of ~2.5 than the rest of the results. The agreement is within 20% for the short wavelength band around 230 nm between the results of Seery and Britton,⁵ Maric et al.,⁴ and Hubinger and Nee,² where Seery and Britton⁵ report the highest and Hubinger and Nee² the lowest values. There is good agreement, to within ~5-15%, for the stronger band around 375 nm where Seery and Britton⁵ and Tellinghuisen⁷ report the highest and Hubinger and Nee² the lowest cross sections. The discrepancies are larger, up to 50%, in the region of the absorption minimum around 290 nm where Seery and Britton⁵ and Hubinger and Nee² report the highest cross sections and Tellinghuisen⁷ the lowest. Excellent agreement is observed in the long wavelength tail above 450 nm between the data of Maric et al.⁴ and Tellinghuisen⁷ whereas those from Hubinger and Nee² are 50% or more larger and those from Jost³ are lower by ~20–40%. Maric et al.⁴ fit a three-band semi-logarithmic Gaussian distribution function to their 0.2 nm resolution data (200–600 nm) and obtained:

$$\begin{aligned} \sigma(298 \text{ K}) = & 6.52 \times 10^{-20} \times \exp(-54.1 [\ln(227.6/\lambda)]^2) \\ & + 3.86 \times 10^{-19} \times \exp(-97.6 [\ln(372.5/\lambda)]^2) \\ & + 9.99 \times 10^{-20} \times \exp(-66.9 [\ln(442.4/\lambda)]^2) \end{aligned}$$

where λ is the wavelength in nm and σ is the absorption cross section in $\text{cm}^2 \text{ molecule}^{-1}$. The recommended absorption cross sections calculated using this expression are listed in Table 4G-11.

A semi-empirical expression based on the theory of Sulzer and Wieland,⁶ which describes the temperature and wavelength dependence of an absorption spectrum, was derived by Maric et al.⁴ to be

$$\begin{aligned}\sigma(T, \lambda) = & 7.34 \times 10^{-20} \times \tanh^{0.5} \times \exp(-68.6 \times \tanh \times [\ln(227.6/\lambda)]^2) \\ & + 4.35 \times 10^{-19} \times \tanh^{0.5} \times \exp(-123.6 \times \tanh \times [\ln(372.5/\lambda)]^2) \\ & + 1.12 \times 10^{-19} \times \tanh^{0.5} \times \exp(-84.8 \times \tanh \times [\ln(442.4/\lambda)]^2)\end{aligned}$$

where λ is the wavelength in vacuum (200–600 nm), $\tanh = \tanh(hc\omega_e/2kT) = \tanh(318.8/T)$ (with $\omega_e = 443.1 \text{ cm}^{-1}$), and T is the temperature (195–300 K).

Photolysis Quantum Yield and Product Studies: It is expected that BrCl photodissociates with unit quantum yield.

Table 4G-11. Recommended Absorption Cross Sections of BrCl at 298 K

G12. BrOCl (bromochloromonoxy)[Back to Index](#)

(1)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of BrOCl, bromochloromonoxy, was measured at room temperature over the wavelength range 230–390 nm by Burkholder et al.¹ Their results are recommended and given in Table 4G-12.

Photolysis Quantum Yield and Product Studies: No recommendation.

Table 4G-12. Recommended Absorption Cross Sections of BrOCl at 298 K

λ (nm)	$10^{20} \sigma$ (cm ²)	λ (nm)	$10^{20} \sigma$ (cm ²)	λ (nm)	$10^{20} \sigma$ (cm ²)	λ (nm)	$10^{20} \sigma$ (cm ²)

G13. CH₃Br (methyl bromide)[Back to Index](#)

(Recommendation: 15-10, Note: 15-10, Evaluated: 15-10)

Absorption Cross Sections: The UV absorption spectrum of CH₃Br, methyl bromide, has been measured at room temperature by Davidson¹ (205–270 nm), Gordus and Bernstein⁵ (204–260 nm), Robbins¹⁰ (174–270 nm), Uthman et al.¹² (200–260 nm), Molina et al.⁸ (190–290 nm), Felps et al.³ (201.6 nm), Man et al.⁷ (180–264 nm), and over the temperature range 210–295 K by Gillotay and Simon⁴ (180–280 nm). At wavelengths >180 nm and <270 nm, the room temperature values of Gordus and Bernstein,⁵ Robbins,¹⁰ Uthman et al.,¹² Molina et al.,⁸ Gillotay and Simon,⁴ and the values of Davidson¹ at wavelengths >210 nm are in very good agreement, to within 10% and within 2% at the absorption maximum ~201 nm. The value from Felps et al.³ at 202 nm is lower by ~10% than the other studies. The cross section data of Man et al.,⁷ reported graphically, are lower by 20–30% over the entire band in comparison with the other data sets. The recommended absorption cross sections in Table 4G-13 are the mean of the values reported by Gillotay and Simon⁴ and Robbins¹⁰ for the range 182–188 nm, the mean of the values reported by Gillotay and Simon,⁴ Uthman et al.,¹² and Robbins¹⁰ for the range 190–198 nm, the mean of the values reported by Gillotay and Simon,⁴ Molina et al.,⁸ Uthman et

al.,¹² and Robbins¹⁰ for the range 200–260 nm, the mean of the values reported by Gillotay and Simon,⁴ Molina et al.,⁸ and Robbins¹⁰ for the range 262–268 nm; the mean of the values reported by Gillotay and Simon⁴ and Molina et al.⁸ for the range 270–280 nm, and the data from Molina et al.⁸ for the range 285–290 nm. A wavelength independent cross section uncertainty factor of 1.2 (2 σ) is assigned for the recommended wavelength range.

The VUV absorption spectrum at 298 K was measured by Olney et al.⁹ (2.8–199 nm) and Locht et al.⁶ (50–207 nm). A Lyman- α cross section of 3.2×10^{-17} cm² molecule⁻¹ from the Locht et al. study is recommended with an uncertainty factor of 1.3 (2 σ), which covers the range in the available experimental data.

Gillotay and Simon⁴ report a slight temperature dependence in the absorption cross sections for wavelengths >220 nm where the values decrease with decreasing temperature. Gillotay and Simon⁴ parameterized the cross sections and the temperature dependence using an empirical polynomial expansion:

$$\log_{10} \sigma(\lambda, T) = \sum A_n \lambda^n + (T-273) \times \sum B_n \lambda^n$$

and reported calculated values for T = 210, 230, 250, 270, and 295 K. However, the fit parameters given in Gillotay et al. result in a systematic bias in the calculated cross sections at wavelengths greater than 200 nm and a poor fit to their experimental data at shorter wavelengths. A re-fit of their data yielded the A_n and B_n parameters below, which are valid for the wavelength range 210–290 nm and temperature range 210–300 K. The re-fit removes the systematic bias and reproduces the experimental data to within 5%, while improving the short wavelength fit although deviations are still significant. This fit is recommended.

A ₀ = 7.997	B ₀ = 0.457415
A ₁ = -0.889724	B ₁ = -0.00882996
A ₂ = 0.00838084	B ₂ = 6.40235×10^{-5}
A ₃ = -3.03191×10^{-5}	B ₃ = -2.06827×10^{-7}
A ₄ = 3.69427×10^{-8}	B ₄ = 2.51393×10^{-10}

Photolysis Quantum Yield and Product Studies: Quantum yields for Br and H atom formation in the photodissociation of CH₃Br were measured at 298 K by Talukdar et al.¹¹ The quantum yields for Br atom formation were found to be close to unity, $\Phi(\text{Br}) = 1.05 \pm 0.11$, 1.10 ± 0.20 , and 1.01 ± 0.16 at 193, 222, and 248 nm, respectively. The quantum yield for H atom formation in the photolysis at 193 nm was measured to be $\Phi(\text{H}) = 0.002 \pm 0.001$, whereas H atoms could not be detected in the photolysis at 222 and 248 nm. Using broadband flash photolysis of CH₃Br, Ebenstein et al.² reported a Br*(²P_{1/2}) fractional yield, Br*(²P_{1/2})/(Total Br), of 0.15 ± 0.12 .

Table 4G-13. Recommended Absorption Cross Sections of CH₃Br at 296 K

λ (nm)	$10^{20} \sigma$ (cm ²)	λ (nm)	$10^{20} \sigma$ (cm ²)	λ (nm)	$10^{20} \sigma$ (cm ²)

G14. CH₂Br₂ (dibromomethane)

[Back to Index](#)

(Recommendation: 06-2, Note: 10-6, Evaluated: 10-6)

Absorption Cross Sections: The UV absorption spectrum of CH₂Br₂, dibromomethane, has been measured at room temperature by Molina et al.³ (200–300 nm), Gillotay et al.^{1,2} (174–290 nm), and Mössinger et al.⁴ (215–300 nm). The absorption cross sections are in good agreement in the range 200–255 nm, to within 10%, and at 275 nm they are within 30%. The recommended absorption cross sections in Table 4G-14 are the values from Gillotay et al.^{1,2} in the region 174–198 nm, the mean of the values reported by Molina et al.³ and Gillotay et al.^{1,2} for the range 200–215 nm, the mean of the values reported by the three groups for the range 220–290 nm, and values from Mössinger et al.⁴ for the range 295–300 nm. On the basis of the level of agreement among the available studies, cross section uncertainty factors (2σ) of 1.05 (200–250 nm), 1.1 (250–270 nm), and 1.2 (270–300 nm) are estimated for the wavelength ranges given in parenthesis.

The absorption spectrum temperature dependence was measured by Gillotay et al.^{1,2} (174–290 nm) over the temperature range 210–295 K and Mössinger et al.⁴ (215–300 nm) over the range 250–348 K. The absorption cross sections decrease at wavelength >~235 nm and increase between 235 and 207 nm with decreasing temperature. At shorter wavelengths, Gillotay et al.^{1,2} report a slight increase in the cross sections in the range 175–189 nm and a slight decrease around the maximum near 200 nm. Gillotay et al.^{1,2} parameterized the cross sections and the temperature dependence using an empirical polynomial expansion:

$$\log_{10} \sigma(\lambda, T) = \sum A_n \lambda^n + (T-273) \times \sum B_n \lambda^n$$

and report calculated values for T = 210, 230, 250, 270, and 295 K. The A_n and B_n parameters, which are valid for the wavelength range 210–290 nm and temperature range 210–300 K are given below.

$$\begin{array}{ll} A_0 = -70.211776 & B_0 = 2.899280 \\ A_1 = 1.940326 \times 10^{-1} & B_1 = -4.327724 \times 10^{-2} \\ A_2 = 2.726152 \times 10^{-3} & B_2 = 2.391599 \times 10^{-4} \\ A_3 = -1.695472 \times 10^{-5} & B_3 = -5.807506 \times 10^{-7} \\ A_4 = 2.500066 \times 10^{-8} & B_4 = 5.244883 \times 10^{-10} \end{array}$$

Mössinger et al.⁴ parameterized their cross section data using the expression:

$$\ln \sigma(\lambda, T) = \ln \sigma(\lambda, 298 \text{ K}) + B(\lambda) (T-298)$$

for the ranges 215–300 nm and 250–348 K. The parameterizations given by Gillotay et al.^{1,2} and Mössinger et al.⁴ yield cross sections that agree at 250 K to within 5% in the range 215–265 nm and to within 10% in the range 270–285 nm. The $B(\lambda)$ coefficients from Mössinger et al.⁴ are given in Table 4G-14 and recommended for use in model calculations.

Photolysis Quantum Yield and Product Studies: It is expected that photolysis will rupture the C-Br bond with unity quantum yield.

Table 4G-14. Recommended Absorption Cross Sections of CH₂Br₂ at 298 K

λ (nm)	$10^{20} \sigma$ (cm ²)	λ (nm)	$10^{20} \sigma$ (cm ²)	$10^3 B$ (K ⁻¹)	λ (nm)	$10^{20} \sigma$ (cm ²)	$10^3 B$ (K ⁻¹)

G15. CHBr₃ (tribromomethane, bromoform)

[Back to Index](#)

(Recommendation: 15-10, Note: 15-10, Evaluated: 15-10)

Absorption Cross Sections: The UV absorption spectrum of CHBr₃, tribromomethane (bromoform), has been measured by Gillotay et al.³ (170–310 nm, 240–295 K), Moortgat et al.⁴ (286–362 nm, 256–296 K), and Papanastasiou et al.⁵ (300–345 nm, 260–330 K). The agreement in the cross sections reported in these studies at wavelengths less than 310 nm is very good. Moortgat et al. reported possible complications to their measurements at the longer wavelengths due to the possible presence of impurities as well as optical artifacts arising from adsorption of CHBr₃ on the cell windows. The Papanastasiou et al. study addressed these potential complications in their cavity ring-down spectroscopy measurements, while also addressing contributions from Rayleigh scattering. The recommended cross sections in Table 4G-15 are the values from Gillotay et al. for the range 170–258 nm and for wavelengths greater than 258 nm from the spectrum parameterization of Papanastasiou et al. given below.

The absorption cross sections increase around the three absorption maxima in the ranges 178–189 nm, 194–208 nm, and 208–234 nm, and decrease at wavelengths <179 nm, over the range 189–194 nm, and >235 nm with decreasing temperature. Gillotay et al.³ parameterized the cross sections and the temperature dependence using an empirical polynomial expansion:

$$\log_{10}(\sigma(\lambda, T)) = \sum A_n \lambda^n + (T-273) \times \sum B_n \lambda^n$$

and report calculated values for 210, 230, 250, 270, and 295 K. The A_n and B_n parameters, which are valid for the wavelength range 240–310 nm and temperature range 210–300 K are given below.

$$\begin{array}{ll} A_0 = -110.2782 & B_0 = -1.5312 \times 10^{-1} \\ A_1 = 1.0281 & B_1 = 1.6109 \times 10^{-3} \\ A_2 = -3.6626 \times 10^{-3} & B_2 = -5.8075 \times 10^{-6} \\ A_3 = 4.1226 \times 10^{-6} & B_3 = 7.2893 \times 10^{-9} \end{array}$$

Moortgat et al.⁴ parameterized their data using the expression:

$$\sigma(\lambda, T) = \exp [(0.06183 - 0.000241 \lambda) (273 - T) - (2.376 + 0.14757 \lambda)]$$

for the wavelength range 290–340 nm and temperature range 210–300 K.

Papanastasiou et al. parameterized the CHBr₃ spectrum using their experimental data and the data from Gillotay et al. and Moortgat et al. between 260–310 nm using the expression:

$$\log_{10}(\sigma(\lambda, T)) = \sum A_n \lambda^n + (296 - T) \times \sum B_n \lambda^n$$

The obtained parameters are

i	A _i	B _i
0	-32.6067	0.1582
1	0.10308	-0.0014758
2	6.39 × 10 ⁻⁵	3.8058 × 10 ⁻⁶
3	-7.7392 × 10 ⁻⁷	9.187 × 10 ⁻¹⁰
4	-2.2513 × 10 ⁻⁹	-1.0772 × 10 ⁻¹¹
5	6.1376 × 10 ⁻¹²	—

and the parameterization is valid over the wavelength range 260–345 nm for temperatures in the range 260–330 K. This parameterization is recommended, while the Gillotay et al. parameterization is recommended for wavelengths <260 nm. A cross section uncertainty factor (2σ) of 1.2 (330–345 nm) and 1.1 (240 to <330 nm) is assigned to the room temperature spectrum.

The VUV absorption spectrum was measured by Causley and Russell² (112–190 nm) and the absorption cross section at Lyman-α was measured by Vasta and Volpp⁷ at 298 K. A Lyman-α cross section of 7.1 × 10⁻¹⁷ cm² molecule⁻¹ from the direct study of Vasta and Volpp is recommended. There is good agreement between these two studies at Lyman-α and an uncertainty factor of 1.1 (2σ) is assigned.
