53. **HNO₃ + NaCl(s) and NaCl(aq).** Recommendation is based on an average of the values of Hoffman et al.,⁸ Ghosal and Hemminger,⁶ the data of Davies and Cox³ as revised by Ghosal and Hemminger⁶ using their model for surface reactivation, and the single crystal data of Leu et al.¹² Hoffman et al.⁸ used less than a single layer of particles so that diffusion into the underlying layers is not a factor to obtain an initial value of $\gamma_0 = (2.3 \pm 1.9) \times 10^{-3}$ (2σ). This is consistent within the combined experimental errors with a value of $(1.3 \pm 0.6) \times 10^{-3}$ determined from the formation of nitrate on the surface of single crystal (100) NaCl by Ghosal and Hemminger,⁶ and with a value of 1.1×10^{-3} from application of the Ghosal and Hemminger model to the Davis and Cox data.³ Ghosal and Hemminger suggest that the value could be as high as 5×10^{-3} for NaCl powders that have more steps and edges that hold SAW.⁷ At longer reaction times, the steady-state value⁸ is a factor of two smaller, $\gamma = 1 \times 10^{-3}$. The reaction is hypothesized to occur both on dry terraces, which saturate rapidly, and on steps and edges that hold surface-adsorbed water. The water acts to recrystallize the product NaNO₃ so that the surface does not passivate during the reaction at atmospherically relevant HNO₃ pressures. This model, developed and modified by several research groups^{2,3,6,8} brings together most of the seemingly disparate measurements of the reaction probability made using a variety of techniques including flow tubes,³ Knudsen cells,^{2,4,5,8} and XPS studies of nitrate formation on single crystals.^{6,7,17} The only gas phase product observed is HCl, with a yield that is within experimental error of 100%. The higher value of $(1.3 \pm 0.4) \times 10^{-2}$ of Leu et al.¹² was obtained by correcting even larger measured values using a pore diffusion model;^{9,10} the corrections were typically in the range of a factor of 4–6. On single crystal NaCl where such corrections were not necessary, Leu et al.¹² measured a value of $(2.4 \pm 0.6) \times 10^{-3}$. A value of $(4 \pm 1) \times 10^{-2}$ was measured using a molecular diffusion tube technique by Koch et al.¹¹ The corrected value of $(8.7 \pm 1.4) \times 10^{-5}$ reported by Zangmeister and Pemberton^{18,19} using Raman spectroscopy to follow the nitrate formed on the surface is lower than the other values likely because a much higher HNO₃ concentration was used ($\sim 10^{18} \text{ cm}^{-3}$), which would lead to a

larger coverage of the surface by the recrystallized NaNO₃ product and passivation of much of the NaCl surface.

Abbatt and Waschewsky¹ measured the loss of gas-phase HNO₃ in a flow tube containing deliquesced 1–5 µm NaCl particles (75% RH) and obtained a lower limit to the uptake coefficient for HNO₃ of 0.2 on unbuffered NaCl. Stemmler et al.¹⁵ report a value of 0.5 ± 0.2 for the initial uptake coefficient on deliquesced particles at 60% RH. Tolocka et al.¹⁶ followed the reaction of HNO₃ with 100–220 nm NaCl particles at 80% RH using single particle MS to measure the Cl[−]/NO₃[−] ratio; the uptake coefficient for 100 nm particles was $(4.9 \pm 2.7) \times 10^{-3}$ and increased with droplet size. Saul et al.¹⁴ have extended the Tolocka et al. work, by studying the reaction over a wide range of relative humidities, both above and below the efflorescence point. Uptake coefficients on the mixed nitrate-chloride particles reach a maximum of 0.12 or so at 50% RH, decreasing at both higher and lower RHs. The presence of hygroscopic MgCl₂ increases the uptake coefficient at low RHs, where the particles may remain liquid. Liu et al.¹³ using static particles probed spectroscopically determine the maximum uptake coefficients to be 0.2 (uncertainty a factor of three), also close to 50% RH, decreasing at higher and lower RHs. The combination of these studies shows that the initial uptake of HNO₃ into solution is fast, with $\gamma_0 > 0.2$; as the solution becomes acidified, HCl is expelled as the gaseous product. The uptake coefficient may decrease when the reaction proceeds on processed particles, where a large amount of nitrate has built up. In such cases, the maximum reactivity is at close to 50% RH. Note that the Stemmler et al.¹⁵ study illustrated that monolayer coverages of long-chain surfactants can reduce the initial uptake coefficient by over an order of magnitude.

- 54. HNO₃ + NaBr and KBr.** Fenter et al.¹ reported that the value of γ for uptake of HNO₃ on NaCl, NaBr, KBr and KCl was the same, $(2.8 \pm 0.3) \times 10^{-2}$, independent of sample mass. Koch et al.² reported an uptake coefficient of HNO₃ on KBr of $(2 \pm 1) \times 10^{-2}$ using a molecular diffusion tube technique. As discussed in Note 7, integration of the results of an extensive series of studies in different laboratories using different techniques, uptake coefficients for HNO₃ on NaCl give a value for the HNO₃-NaCl reaction that is smaller than measured in the Fenter et al.¹ and Koch et al.² studies. These values for KBr may therefore be upper limits. Leu et al.³ reported a value that is an order of magnitude smaller, $(2.8 \pm 0.5) \times 10^{-3}$ after applying large corrections (about an order of magnitude) for pore diffusion; the average uncorrected value using the geometric area was 0.027.

- 55. HNO₃ + sea salt.** The uptake coefficient for HNO₃ on synthetic sea salt¹ is much larger than that on NaCl, which is attributed to the very hygroscopic nature of sea salt due to such components as the magnesium chloride and its hydrates (see Note on O₃ + sea salt). De Haan and Finlayson-Pitts¹ reported initial uptake coefficients of γ_0 in the range of 0.07 to 0.75 and steady state values in the range of 0.03 to 0.25; these were measured using salt layers from 2 layers to 10³ layers. The initial uptake coefficient on MgCl₂•6H₂O was ≥ 0.4 and the steady-state value > 0.1 . At these high uptake values, the correction for diffusion into underlying layers is expected to be small. The large uptake coefficient on sea salt is consistent with the values measured for uptake on concentrated aqueous solutions of NaCl and the high water content of the surface of sea salt (see O₃ + seasalt Note above). The yield of HCl was within experimental error of 100%. Guimbaud et al.² measured the uptake coefficient of HNO₃ on 70 nm supersaturated sea-salt particles (deliquesced particles held at 55% RH) to be 0.50 ± 0.20 ; they concluded that this was the mass accommodation coefficient.

- 56. HNO₃ + Al₂O₃.** Börensén et al.¹ used diffuse reflectance FTIR observations to show that HNO₃ reacts with surface hydroxyl groups on γ -alumina at 299 K to produce surface bonded nitrate, while Goodman et al. reported similar observations for α -alumina at 296 K.² Goodman et al.² also observed that higher relative humidity lead to higher HNO₃ uptake. They integrated their nitrate absorbance feature to yield a time averaged uptake coefficient of $(4 \pm 1) \times 10^{-8}$.² Underwood et al.⁵ report a linear mass dependent, BET corrected γ_0 for α -alumina at 295 K of $(9.7 \pm 0.5) \times 10^{-5}$. Hanisch and Crowley also measured liner mass

dependent γ_o s on α -alumina (at 298 K) for four particle sizes, which yielded an average value of 0.133 ± 0.033 .³ They argue that the lack of variance of γ_o s on a large range of particle sizes and masses indicate that the BET correction to the geometrical surface area is not required. They also measured γ_o for an unpolished single crystal of $(1.6 \pm 1.4) \times 10^{-3}$ and smaller values on polished single crystals, showing the higher density of surface defect sites on small amorphous particle are critical for their high reactive active uptake coefficients. The recommendation is based on the Hanisch and Crowley data and analyses for particulate samples.³ Seisel et al.,⁴ used Knudsen cell uptake experiments at 298 K to measure an initial uptake (γ_o) value of 0.13 ± 0.02 for γ -alumina with HNO_3 vapor concentrations of $\sim 10^{11} \text{ cm}^{-3}$. Lower values of γ were observed for higher nitric acid partial pressures; water vapor was observed as a product. They also performed DRIFTS experiments that yielded a mean uptake coefficient for surface nitrate formation of $(7.7 \pm 0.8) \times 10^{-3}$ at 298 K.

57. **$\text{HO}_2\text{NO}_2 + \text{HCl}$ on $\text{H}_2\text{SO}_4 \cdot n\text{H}_2\text{O}(\text{l})$.** Zhang et al.¹ performed wetted-wall flow-reactor studies with HCl and HO_2NO_2 partial pressures in the 10^{-6} to 10^{-7} Torr range. Using chemical ionization mass spectrometry (CIMS) to detect expected reaction products, no Cl_2 (using SF_4^- as an analyte ion) or HOCl (using F^-) was detected over a temperature range of 200–225 K and an acid concentration range of 50–70 wt% H_2SO_4 . An upper limit for the reactive uptake coefficient for HO_2NO_2 reacting with HCl of $\gamma < 1 \times 10^{-4}$ was deduced.

58. **$\text{NH}_3 + \text{H}_2\text{SO}_4 \cdot n\text{H}_2\text{O}$.** Robbins and Cadle,⁶ Huntzicker et al.,⁴ McMurry et al.,⁵ and Daumer et al.¹ all studied NH_3 uptake by sulfuric acid aerosols in near room temperature flow reactors ($T = 281\text{--}300 \text{ K}$). Uptake coefficients varied between 0.1 and 0.5. Rubel and Gentry⁷ used levitated H_3PO_4 acid droplets to show that heterogeneous reaction does control the initial NH_3 uptake on strong acid solutions. Both Rubel and Gentry and Däumer et al. also explored the effect of organic surface coatings. Swartz et al.⁸ used a droplet train flow reactor to measure reactive uptake coefficients on 20 to 70 wt% acid over a temperature range from 248 to 288 K. Measured uptake coefficients varied from 1.0 at 55 wt% and above to 0.3 at 20 wt% and drop off smoothly to the pure water results reported by the same group, as well as other droplet train flow reactor and coaxial jet uptake studies.⁹ Hanson and Kosciuch² used an aerosol flow reactor to measure reactive uptake coefficients at room temperature (287 to 297 K) from 15 to 65 wt%. While the data have a fair amount of scatter, taken as a whole they are consistent with $\gamma = 1$ over the whole range of acid concentrations. There is no obvious reason for the discrepancy between the 15 to ~45 wt% results from Swartz et al.⁸ and Hanson and Kosciuch,² the two groups have discussed conceivable issues at length in print⁹ and Hanson and Kosciuch.³

59. CO₂ + Al₂O₃(s). Parkyns¹ and Szanyi and Kwak² each report FTIR studies of CO₂ chemisorbed on γ -alumina surfaces annealed at temperatures up to ~800 K. They report that CO₂ can react with the HO-Al surface sites of γ -alumina at room temperature to form adsorbed bicarbonate structures. They also show that the surface OH on γ -alumina can be eliminated by calcination of the alumina surfaces at temperatures near 800 K. Adsorbed CO₂ on the dehydroxylated γ -alumina forms weakly bound carbonate species. No kinetic uptake data are available for CO₂ uptake.

60. H₂CO + Al₂O₃(s). Carlos-Cueller et al.¹ reported Knudsen cell studies that determined γ_0 values for oxygenated volatile organic compounds (VOCs) at 295 K. They measured a γ_0 on α -alumina for formaldehyde of $(7.7 \pm 0.3) \times 10^{-5}$, based on BET surface areas and the KML² correction for porosity; relatively “sticky” formaldehyde may not access the full BET surface and thus γ_0 may be underestimated. Xu et al.³ used a DRIFTS Reactor with γ -Al₂O₃ surfaces over a temperature range of 84–573 K and a RH range of 0–80%. BET and geometric surface areas were used to calculate initial uptake coefficients. Formaldehyde uptake was independent of gas phase O₂ over the studied range ($0.18\text{--}730 \times 10^{13} \text{ cm}^{-3}$); uptake was negatively correlated with RH. Surface analyses included FTIR, X-ray Diffraction and SEM. The initial surface product is dioxymethylene that is oxidized to formate, with reaction order of 0.74 ± 0.05 . Polyoxymethylene is a secondary adsorbed product. Reactive uptake saturates active surface sites so initial γ_0 values are reported for both geometric and BET surface areas. For T = 298 K, $\gamma_0(\text{Geo}) = (3.6 \pm 0.8) \times 10^{-4}$ and $\gamma_0(\text{BET}) = (1.4 \pm 0.31) \times 10^{-8}$ (T = 298 K, RH = 0); $\gamma_0(\text{BET}, 298 \text{ K})$ decreases approximately a factor of 2 as RH increases from 0 to 80%; $\gamma_0(\text{BET}, 0 \text{ RH})$ increases irregularly by approximately a factor of 3 as T increases from 273 to 373 K. The Xu et al. room temperature BET value for γ -Al₂O₃ is ~5000 lower than the Carlos-Cueller et al. value for α -alumina. It is unclear how much of this is due to systematic error in one or both experiments and how much is due to different surface properties for the two alumina phases. Given the available data an upper limit of $\gamma_0 < 5 \times 10^{-4}$ over the temperature range of 270–300 K is estimated for both phases.

61. **CH₃OH + H₂SO₄•nH₂O(l) and H₂SO₄•mHNO₃•nH₂O(l).** Van Loon and Allen² report spectroscopic observations at 293 K for 0 to 96.5 wt% H₂SO₄ exposed to methanol vapor. They observed rapid surface adsorption and saturation, followed by slower bulk absorption. For acid concentrations between 47.1 and 63.3 wt% they observed surface reaction between methanol and sulfuric acid that formed methyl hydrogen sulfate, CH₃SO₄H. Iraci et al.¹ used infrared spectroscopy to monitor the production of gas phase methyl nitrate, CH₃ONO₂, from the bulk reaction of ternary sulfuric acid/nitric acid/water solutions with 0.00005–0.005 M CH₃OH in 50.5 to 63.6 wt% H₂SO₄ with 0.03–0.21 M HNO₃ between 278.2 and 328.6 K. Within this range methyl nitrate production increased linearly with methanol and nitric acid concentration and exponentially with sulfuric acid concentration. At high acid concentrations nitric acid reacts with protons to form water and the nitronium ion, NO₂⁺; methyl nitrate production was observed to be proportional to the NO₂⁺ concentration indicating it was the nitrating agent.

62. **CH₃OH + Al₂O₃(s).** Carlos-Cueller et al.¹ reported Knudsen cell studies that determined γ_o values for oxygenated volatile organic compounds (VOCs) at 295 K. They measured γ_o on α -alumina for methanol of $(1.0 \pm 0.7) \times 10^{-4}$, based on BET surface areas and the KML² correction for porosity. Since data is only available from a single laboratory using only a single method, an upper limit of $\gamma_o < 3 \times 10^{-4}$ is recommended for α -Al₂O₃.

63. **HC(O)OH + Al₂O₃(s).** Tong and co-workers^{3,4} used a DRIFTS reactor to investigate the uptake of formic acid on beds of α -Al₂O₃ particles; surface areas were estimated with BET measurements as well by geometric sample area. Their initial study³ reported $\gamma(\text{BET})$ and $\gamma(\text{Geo})$ for formic, acetic and propionic acids on α -Al₂O₃ at 300 K over a RH range (0–90%). For RH(0) they reported:

Acid	$\gamma(\text{BET})$	$\gamma(\text{Geo})$
HC(O)OH	$(2.37 \pm 0.30) \times 10^{-7}$	$(2.07 \pm 0.26) \times 10^{-3}$
CH ₃ C(O)OH	$(5.99 \pm 0.78) \times 10^{-7}$	$(5.00 \pm 0.69) \times 10^{-3}$
CH ₃ CH ₂ C(O)OH	$(3.03 \pm 0.52) \times 10^{-7}$	$(3.04 \pm 0.63) \times 10^{-3}$

It is likely that $\gamma(\text{BET})$ underestimates the true uptake coefficient since organic acids adsorb and react before penetrating some pores and that $\gamma(\text{Geo})$ overestimates uptake rates. The effect of relative humidity on the HC(O)OH uptake co-efficients is modest, with a slight (~10%) rise between RH(0) and RH(20%) and then a gradual fall off (~33%) between RH(20%) and RH(95%). A second publication by Tong and co-workers⁴ focused on the effects of temperature on uptake rate. For RH(0) they measured a modest increase (less than a factor of two) as T decreases from 298 to 240 K:

T (K)	$\gamma(\text{BET})$	$\gamma(\text{Geo})$
298	$(1.34 \pm 0.02) \times 10^{-6}$	$(2.35 \pm 0.03) \times 10^{-3}$
285	$(1.52 \pm 0.04) \times 10^{-6}$	$(2.65 \pm 0.07) \times 10^{-3}$
277	$(1.70 \pm 0.03) \times 10^{-6}$	$(2.98 \pm 0.03) \times 10^{-3}$
273	$(1.77 \pm 0.01) \times 10^{-6}$	$(3.09 \pm 0.03) \times 10^{-3}$
263	$(1.96 \pm 0.02) \times 10^{-6}$	$(3.43 \pm 0.04) \times 10^{-3}$
250	$(2.22 \pm 0.02) \times 10^{-6}$	$(3.89 \pm 0.03) \times 10^{-3}$

$$240 \quad (2.39 \pm 0.03) \times 10^{-6} \quad (4.18 \pm 0.05) \times 10^{-3}$$

Note that their earlier $\gamma(\text{Geo})$ for room temperature and $\text{RH}(0)$ of $(2.07 \pm 0.26) \times 10^{-3}$ is in good agreement with the value of $(2.35 \pm 0.03) \times 10^{-3}$ reported in Wu et al.;⁴ however, their later room temperature $\gamma(\text{BET})$ value is more that a factor of five larger than their earlier value, calling into question the reliability of BET surface area determinations. Infrared spectra indicated surface enhanced crystallization of HCOOH at lower temperatures as well reaction with surface hydroxyl groups to form formate. Based on these data only an upper limit of $\gamma_o < 0.01$ is recommended for $\alpha\text{-Al}_2\text{O}_3$.

Rubasinghege et al.² used a Quartz Crystal Microbalance (QCM) and Attenuated Total Reflectance FTIR (ATR-FTIR) to characterize total HC(O)OH uptake and surface reactions on $\gamma\text{-Al}_2\text{O}_3$, SiO_2 and kaolinite surfaces at T (298 K) and RH (<1%); no kinetic data was presented. They observed both reversible and irreversible adsorption of HC(O)OH on $\gamma\text{-Al}_2\text{O}_3$. Adsorbed water, controlled by RH, increases the irreversible uptake of HC(O)OH . The resulting layer of adsorbed formate decreases the surface hydrophilicity, decreasing the amount of water uptake. Raun et al.¹ report a density functional simulation of HC(O)OH interacting with an $\alpha\text{-Al}_2\text{O}_3$ (0001) surface, presenting adsorbate dissociation pathways and estimating the energy barrier for dehydration reactions.

64. **$\text{CH}_3\text{CH}_2\text{OH} + \text{H}_2\text{SO}_4 \cdot n\text{H}_2\text{O}$.** Timonen and Leu² used a trough flow reactor to measure uptake coefficients for ethanol on 41.1 to 79.3 wt% H_2SO_4 , for selected temperatures between 193 to 273 K, but primarily for temperatures from 203 to 258 K. Uptake coefficients for 70.3–79.3 wt% acid showed little temperature variation, starting at ~ 0.07 for 203 K and falling to 0.05 to 0.06 above 250 K, while uptake coefficients for 41.1 to 64.1 wt% started at ~ 0.07 at 203 K and decreased to about 0.02 at 233 K for 41.1 wt% 1, to ~ 0.03 at 243 K for 54.4 wt% and ~ 0.035 at 253 K for 64.1 wt%. Uptake was only partially reversible, so it was attributed to both physical and reactive processes, making the reported uptake coefficients as upper limits for γ . The authors attributed the reactive portion of the uptake to esterification reactions, forming ethyl hydrogen sulfate and diethyl sulfate, and saw some mass spectral evidence for these products when they mixed ethanol with 80 wt% acid in their reactor at 296 K. Michelsen et al.¹ found no evidence for ethyl hydrogen sulfate in Knudsen cell ethanol uptake experiments for 39–76 wt% H_2SO_4 over a 209–237K temperature range, so the extent of reaction for low temperature acid solutions remains uncertain. Timonen and Leu suggest that at low ethanol vapor fluxes surface reactivity may be important.

65. **$\text{CH}_3\text{C(O)OH} + \text{Al}_2\text{O}_3(\text{s})$.** Carlos-Cueller et al.¹ reported Knudsen cell studies that determined γ_o values for oxygenated volatile organic compounds (VOCs) at 295 K. They measured a γ_o on α -alumina for acetic acid of $(2 \pm 1) \times 10^{-3}$, based on BET surface areas and the KML² correction for porosity; “sticky” acetic acid may not access the full BET surface and thus γ_o may be underestimated. Tong et al.³ used a DRIFTS

reactor to investigate the uptake of acetic acid on beds of α -Al₂O₃ particles at 300 K; surface areas were estimated with BET measurements as well by geometric sample area. For RH(0) they reported $\gamma(\text{BET}) = (5.99 \pm 0.78) \times 10^{-7}$ and $\gamma(\text{Geo}) = (5.00 \pm 0.69) \times 10^{-3}$; this $\gamma(\text{BET})$ is over 3000 times smaller than that reported by Carlos-Cuellar et al.¹ Given the disparity between the two values only an upper limit of $\gamma_0 < 0.02$ for α -Al₂O₃ is recommended.

- 66. CH₃CHO + H₂SO₄•nH₂O.** Knudsen cell uptake measurements are reported by Michelsen et al.³ for 38.5–76.2 wt% H₂SO₄ over a temperature range of 211–241 K, with evidence of reactive uptake for some temperatures in the 38.5–66.3 wt% H₂SO₄ range. Using a rotating wetted-wall flow reactor Esteve and Nozière² measured small, probably solubility constrained, uptake coefficients at 298 ± 3 K for 96 wt% and 89.4 wt% of 9.4×10^{-6} and 4.2×10^{-7} , respectively. Michelsen et al. found uptake over the 211–241 K temperature range was controlled by Henry's law solubility, and had a complex dependence on acid concentration due to competition among the reversible bulk phase processes of physical dissolution, hydration to form the gem diol, protonation and enolization, all of which affect H*. They also saw evidence for aldol condensation at some temperatures for acid concentrations of 66.3 wt% and below. Drawing on the complex aldol condensation mechanism presented to explain the bulk kinetic studies of Baigrie et al.,¹ Michelsen et al. present plausible arguments why non-reversible condensation reactions might have the complex dependence on acid concentrations and temperature that they observed. Given its relatively small rate constant, they suggest that aldol condensation bulk reactions will play a negligible role for typical aldehyde concentrations in the atmosphere.

- 67. CH₃CHO, CH₃CH₂CHO and CH₃C(O)CH₃ + Al₂O₃(s).** Li et al.¹ reported Knudsen cell studies that determined γ_0 values for oxygenated volatile organic compounds (VOCs) at 298 K. They reported very similar BET corrected γ_0 s values on α -alumina for acetaldehyde (3.2×10^{-5}), propionaldehyde (4.7×10^{-5}), and acetone (2.0×10^{-5}). For molecules this large BET surface area may not be assessable and derived γ_0 s may be underestimated. Since data are from a single laboratory using only one technique, only conservative lower limits are recommended.

69. **CH₃C(O)O₂ + H₂O(l) and H₂SO₄•nH₂O.** Villalta et al.¹ used wetted-wall flow tube techniques to measure $\gamma = 4.3 (+ 2.4 / -1.5) \times 10^{-3}$ for water at 274 ± 3K. They also measured uptake for 34 wt% H₂SO₄ at 246 K ($\gamma = (2.7 \pm 1.5) \times 10^{-3}$), 51 wt% at 273 K ($\gamma = (0.9 \pm 0.5) \times 10^{-3}$), and 71 wt% at 298 K ($\gamma = (1.4 \pm 0.7) \times 10^{-3}$). They suggest that products subsequent to hydrolysis are HO₂ and CH₃C(O)OH.

70. **H₂C=C(CH₃)CHO and H₂C=CHC(O)CH₃ + Al₂O₃(s).** Zhao et al.¹ report a coated wall flow reactor study with Transmission FTIR measurements of adsorption and reaction of both methacrolein (MAC) and methyl vinyl ketone (MVK) on α -Al₂O₃ at T~300 K and relative humidity values of RH <1%, 20% and 60%. They reported RH = 0 γ_o values based on BET surface areas of: $\gamma_o(\text{MAC}) = (2.0 \pm 0.5) \times 10^{-8}$ and $\gamma_o(\text{MVK}) = (3.8 \pm 0.8) \times 10^{-8}$. They measured significantly lower γ_o s for RH = 20 and 60% indicating that water vapor blocks reactive surface sites. Major products (>0.03) were CH₃CH₂CHO, HCHO and HCOOH for MAC and isomerization of MVK to CH₃CH=CHCHO (crotonaldehyde) that then reacted to produce CHOCHO, CH₃CHO and CH₃C(O)OH. For molecules this large some BET surface area may not be accessible and derived γ_o s may be underestimated. Given the strong impact of relative humidity and uncertainty in effective surface area no recommendations for γ_o s are made.

71. **CH₃C(O)O₂NO₂ + HCl, Cl, ClO, and OCLO on H₂SO₄•nH₂O(l).** Zhang and Leu¹ performed wetted wall flow reactor studies with Cl species partial pressures in the 10⁻⁶ to 10⁻⁷ Torr range and CH₃C(O)O₂NO₂ at 3 × 10⁻⁶ Torr after equilibrating the acid surfaces (42, 51, and 69 wt% at 202 and 224 K) with CH₃C(O)O₂NO₂. Also uptake studies with 5 × 10⁻⁷ Torr CH₃C(O)O₂NO₂ were performed after exposing the acid surface to the Cl species. No Cl species or CH₃C(O)O₂NO₂ uptake enhancements were observed under either condition and an upper limit for the reactive uptake coefficient of $\gamma < 1 \times 10^{-4}$ of CH₃C(O)O₂NO₂ was deduced. No gas phase reaction products were observed using CIMS after 42 wt% H₂SO₄ at 210 K was exposed to CH₃C(O)O₂NO₂ and each Cl species for 20 minutes.

76. **Cl₂ + NaBr and NaI.** Mochida et al.⁵ used salt powders and spray-deposited films to obtain a value for the initial uptake coefficient of 2×10^{-2} . The measured uptake coefficients for the salt powders were a factor of six larger, but application of the pore diffusion model of Keyser et al.^{3,4} gave this value, which is in agreement with that for a spray-deposited film. Br₂ was generated in a yield of 100%, within experimental error.
- Hu et al.¹ measured the uptake of Cl₂ on aqueous solutions of NaBr and NaI over the temperature range of 263–293 K using a droplet train flow reactor. Measured values of the uptake coefficients on NaBr solutions ranged from 0.16 at 263 K to 0.05 at 293 K, and there was evidence of a surface reaction between Cl₂ and Br⁻ at the air-particle interface. Similarly, the uptake coefficients for Cl₂ on NaI solutions ranged from 0.20 to 0.07 over the same temperature range, again with evidence for a contribution from an interface reaction. Huff and Abbatt² have studied the reaction of Cl₂ with films formed by freezing NaBr solutions at 233 K, observing Br₂ as the reaction product and that the maximum reaction probability is 0.1 when the surface is saturated with bromide ions.

77. **Cl₂ + KBr.** Mochida et al.² used salt powders and spray-deposited films to obtain a value for the initial uptake coefficients. The value measured for salt powders was 0.176, but after correction for pore diffusion, this became 3.7×10^{-2} , similar to a value of 2.3×10^{-2} measured for spray-deposited films. Br₂ was generated in a yield of 100%, within experimental error. Aguzzi and Rossi¹ measured a similar value, 2.7×10^{-2} , using a Knudsen cell. Santschi and Rossi³ reported an initial value of $\gamma_0 = 0.11$ for the uptake of Cl₂ on thin spray-deposited films of KBr that had not been extensively pumped on; this initial value was 4×10^{-2} for films that had been pumped on for hours. They attributed the difference to the removal of surface-adsorbed water (SAW) by extensive pumping.

78. **Cl₂ + sea salt.** Mochida et al.¹ used a synthetic sea salt and a "natural" seasoning sea salt in Knudsen cell studies of the uptake of Cl₂. The synthetic sea salt value of $(2.2 \pm 0.3) \times 10^{-2}$ is the value reported after correction of the measured value of 0.138 using the pore diffusion model. For the "natural" seasoning salt, the measured value was 0.11 which after correction for diffusion into the underlying layers became $(3.1 \pm 1.1) \times 10^{-2}$. Br₂ was the major gas phase product, with small mass spectrometric signals also seen for BrCl.

79. **ClO + H₂O(s) and HNO₃•nH₂O(s).** Proposed reaction (Leu³) is $2 \text{ClO} \rightarrow \text{Cl}_2 + \text{O}_2$; reactive uptake may depend on ClO surface coverage, which in turn may depend on gas phase ClO concentrations. Kenner et al.² measured reaction probabilities of $(8 \pm 2) \times 10^{-5}$ for ice at 183 K which is far lower than the limit of $>1 \times 10^{-3}$ obtained by Leu.³ Abbatt,¹ using nearly the same low levels of ClO as Kenner et al., obtained $\gamma < 1 \times 10^{-5}$ at 213 K. The difference may lie in the level of ClO or other adsorbable reactive species present. The lower value of Abbatt is probably closer to the expected reactivity under stratospheric conditions. Using high concentrations of ClO radicals ($>10^{12}$ molecules/cm³) exposed to ice surfaces at 225 K, McKeachie et al.⁴ infer an uptake coefficient of 0.001, which increases with ClO exposure. Formation of higher chlorine oxides, notably OClO, is observed mass spectrometrically and by UV-VIS spectroscopy, upon warming the ice. It is likely that the high ClO concentrations drive self-reactions on the ice surface. Kenner et al. also measured a reaction probability limit of $< (8 \pm 4) \times 10^{-5}$ for NAT at 183 K.

80. **ClO + H₂SO₄•nH₂O.** Measured reaction probability (Martin et al.²) varies between 2×10^{-5} and 2×10^{-4} as H₂O content is varied by changing wall temperature. Reaction product is claimed to be HCl, not Cl₂. Abbatt¹ measured $\gamma < 1 \times 10^{-5}$ for 60 and 70 wt% H₂SO₄ at 213 K.

81. HCl + HNO₃ on H₂SO₄•mHNO₃•nH₂O(l). Two studies have noted HCl activation in concentrated ternary H₂SO₄/HNO₃/H₂O solutions or ice slurries. Luick et al.² saw only gas phase HCl in 64.6 wt% H₂SO₄/ 4.8 wt% HNO₃ at 200 K, but saw a vapor phase Cl partitioning of 50% HCl and 50% ClNO/ClNO₂ for a 76.6/20.1 wt% solution (an ice slurry) at 200 K. Cappa et al.¹ saw substantial yields of ClNO, ClNO₂, and Cl₂ at 273 K for a range of solution compositions; e.g. 32.6%, 9.8%, and 44.4% respectively for a total HCl conversion of 86.9% in a 35% H₂SO₄/45% HNO₃ solution and 20.2%, 6.9%, 27.9% for a 60/25 wt% solution. While no kinetic coefficients or detailed mechanisms are available, these studies do show the potential for HCl activation in strong H₂SO₄/HNO₃/H₂O solutions.

82. HOCl + HCl + H₂O(s) and HNO₃•3H₂O(s). Hanson and Ravishankara⁵ and Abbatt and Molina¹ have investigated the HOCl + HCl reaction on water ice and NAT-like surfaces, and Chu et al.^{3,4} studied the reaction on water ice. Product yield measurements support the identification of Cl₂ and H₂O as the sole products. The measured yield of product Cl₂ is 0.87 ± 0.20 and was stated to be similar on both surfaces according to Abbatt and Molina. Within the accuracy of the experiments, the reaction probability does not depend on the gas phase HCl and HOCl densities. Only Abbatt and Molina investigated at more than one temperature, their data indicates that γ increases at lower temperatures. A plot of data from the three studies does show a weak temperature trend, with γ increasing about a factor of two as the temperature drops from 202 to 188 K. However, the data are too sparse to assign a definitive temperature dependence. The average of all three studies yields $\gamma = 0.26 \pm 0.08$ for data based on the geometrical area of the flow tube surfaces. Chu et al.³ indicate that a porosity correction for their data would reduce their value by a factor of 3 to 4. The real uncertainty would appear to be dominated by systematic uncertainties in porosity corrections and a potential temperature dependence. Given the fact that any porosity correction must reduce the value, a central value of 0.2 is adopted with an uncertainty factor of 2. The high reaction probabilities measured for water ice indicate that this reaction may play a significant role in release of reactive chlorine from the HCl reservoir.

Two studies (Hanson and Ravishankara⁵ and Abbatt and Molina¹) have measured the reaction probability of HOCl + HCl on NAT surfaces. These data show γ increases as the ambient water pressure increases and then reaches a plateau. At relatively high water pressure, the two studies averaged $\gamma = 0.135 \pm 0.049$, with no porosity correction. The reaction probability on water-poor NAT-like surfaces falls off dramatically (a factor of 10). A recommendation of 0.1 with an uncertainty factor of 2 is shown in Table 5-2. Carslaw and Peter² have published a model of this reaction and its dependence on HCl uptake.

83. **HOCl + HCl + H₂SO₄•nH₂O(l).** This process has been studied in coated flow tubes over ~200–260 K by Zhang et al.,⁷ Hanson and Ravishankara,³ Donaldson et al.,¹ and Hanson and Lovejoy.² Hanson and Lovejoy also made measurements in an aerosol flow tube from 251 to 276 K. A model of this and related sulfuric acid aerosol reactions tailored to stratospheric conditions has been published by Hanson et al.⁴ Zhang et al. held the water vapor partial pressure at 3.8×10^{-4} Torr and showed γ increased by a factor of 50 as the temperature was lowered from 209 to 198 K increasing the water mole fraction, showing that the reaction rate is strongly dependent on water activity. A detailed kinetic uptake model has been developed to fit the experimental data.⁶ The formulation for γ is given as:

$$\frac{1}{\gamma} = \frac{1}{\alpha} + \frac{1}{\Gamma_{HOCl}^{rxn}}$$

where

$$\Gamma_{HOCl}^{rxn} = \frac{4H_{HOCl}RT}{\bar{c}} (D_{HOCl}k_{HOCl,HCl})^{1/2}$$

At the low temperatures of interest, α for HOCl was assumed to be unity consistent with the value for HCl measured at 240 K and below (Robinson et al.⁵). The individual formulations for H_{HOCl} , D_{HOCl} and $k_{HOCl,HCl}$ are given in Table A-4 in Shi et al.⁶ Reaction of HOCl with HCl is considered to be acid catalyzed. It is known that the reaction rate for HOCl + HCl in pure water is low (Donaldson et al.¹). Experimental data noted above indicated that the reaction rate of HOCl + HCl increases with acidity of H₂SO₄ solution. The data from the experimental studies noted above were fit to the model without bias. Using the same error analysis discussed in the note for N₂O₅ uptake on sulfuric acid, a detailed kinetic model yields a 33.4% error (one sigma fit to the available data set, with $\sigma_m = 33.3\%$ and $\sigma_d = 3.0\%$).

In the cold stratosphere where $T < 190$ K, the reaction of ClONO₂ + HCl is so fast that HCl is depleted which slows down the reaction of HOCl + HCl. As shown in Table A-4 in Shi et al., the effect of HCl depletion on the HOCl reactive uptake coefficient (due to reaction with ClONO₂ inside/on the surface of particles) is taken into account via the factor F_{HCl} (also see the note on chlorine nitrate/hydrochloric acid reactive uptake on sulfuric acid surfaces).

84. **HOCl + HBr on H₂O(s).** Chu and Chu¹ measured γ at 189 K to be in the range from 0.06 to 0.38 for HBr partial pressures ranging from 1.1×10^{-7} to 6.6×10^{-5} Torr. At 220 K they measured γ in the range from 0.01 to 0.07 for HBr partial pressures in the range from 7.2×10^{-7} to 1.3×10^{-5} Torr. These γ values were estimated assuming the area of the ice surface to be equal to the geometric area of the cylindrical flow reactor; corrections for surface porosity effects range from a factor of 3 to 10 lower.

- 85. $\text{HOCl} + \text{HBr}$ on $\text{H}_2\text{SO}_4 \cdot n\text{H}_2\text{O}(\text{l})$.** Abbatt and Nowak¹ measured uptake of HOCl in the presence of excess HBr on a 69.3 wt% sulfuric acid solution in a wetted wall flow reactor at 228 K. A second order bulk reaction rate constant, k^{II} , of $2 \times 10^6 \text{ M}^{-1} \text{ s}^{-1}$ was derived; this is a factor of ~ 10 faster than $\text{HOBr} + \text{HCl}$ under the same conditions. Since HOCl and HBr have variable solubilities under stratospheric conditions, characterizing this reaction with a simple uptake coefficient is not appropriate. A full reaction/solubility/liquid phase diffusion model will require further data.

- 86. $\text{HOCl} + \text{NaBr}$ and KBr .** Rossi² reported studies of the uptake of HOCl in a Knudsen cell using KBr powders and spray-deposited thin films. Values for the initial uptake coefficients covered a wide range, from 5×10^{-3} to 0.2, due to changes in the surface from adsorbed reaction products. The major product initially was Br_2 , and subsequently BrCl and HOBr, with much smaller amounts of BrOCl and Br_2O . The mechanism was interpreted as the formation of small amounts of HBr on the surface from hydrolysis of KBr, followed by the reaction of HOCl with adsorbed HBr to form BrCl which then reacts with KBr to form Br_2 . On frozen solutions of NaBr, Huff and Abbatt¹ observe reactivity of HOCl with uptake coefficients between 0.02 and 0.04 at 233 K in a coated-wall flow tube. Br_2 is the gas-phase product, thought to arise from the intermediate BrCl reacting with the bromide film. Although the kinetics are faster on the most acidic films (pH 2), there is no dependence of the acidity of the solution from pH 4 to 10.

- 90. ClNO_2 + KBr, NaBr, NaI and NaCl.** Caloz et al.³ measured the uptake of ClNO_2 on solid KBr at room temperature using a Knudsen cell and salt samples in the form of powders, spray-deposited films, polished windows and depolished windows. The uptake coefficient increased with the number of layers of salt powders; correction of the uptake coefficients using the pore diffusion model gave initial uptake coefficients of $(1.0\text{--}1.3) \times 10^{-4}$, in agreement with values measured for the spray-deposited film (1.0×10^{-4}) and depolished window (1.0×10^{-4}). The value for the polished window was an order of magnitude smaller, as expected since this has much less surface-adsorbed water (SAW) that assists in keeping the surface from becoming passivated. The yield of Br_2 relative to ClNO_2 lost was 0.55 ± 0.2 . Using a diffusion tube method, Koch and Rossi⁷ measured an uptake coefficient of 2.0×10^{-4} , in reasonable agreement with the Knudsen cell results.

The uptake of ClNO_2 on aqueous solutions of NaBr has been shown to increase with the concentration of NaBr. Frenzel et al.⁵ measured the uptake of ClNO_2 on $(0.5\text{--}5) \times 10^{-3}$ M NaBr solutions from 275–291 K using a wetted wall flow tube apparatus; the values of γ increased from 1.2×10^{-5} to 4.0×10^{-5} over this range of NaBr concentrations. Schweitzer et al.⁹ used a droplet train apparatus from 275–288 K; γ increased from 8.6×10^{-6} to 9.4×10^{-4} as the NaBr concentration increased from 10^{-4} to 1.0 M. The main product was Br_2 , with traces of BrNO_2 and BrCl . In a subsequent study,¹⁰ they applied a wetted wall flow tube method from 275–293 K and reported uptake coefficients that were independent of temperature over this range, but again increased with the concentration of NaBr: γ increased from 7.1×10^{-6} at 10^{-4} M NaBr to 9.2×10^{-4} at 1.0 M. Fickert et al.⁴ used a wetted wall flow tube at 274 K and measured an uptake coefficient of 1.1×10^{-5} for 10^{-4} M NaBr, increasing to 1.1×10^{-4} for 10^{-2} M NaBr. The major gas phase products were Br_2 and BrNO_2 , with the yield of BrNO_2 decreasing as the initial bromide ion concentration in solution increased. The mass accommodation coefficient for ClNO_2 on aqueous solutions at 275 K was measured to be $(9 \pm 4) \times 10^{-3}$. A Knudsen cell study by Beichert and Finlayson-Pitts² found $\gamma < 10^{-5}$ on NaCl powders at 298 K.

The uptake of ClNO_2 on solutions of NaI was studied by George et al.⁶ and by Schweitzer et al.^{9,10} The uptake coefficient increases with the concentration of NaI. For example, George et al.⁶ reported that γ_0 increased from 1.1×10^{-3} to 6.6×10^{-3} as the iodide concentration increased from 10^{-3} M to 10^{-2} M at 280 K. This is consistent with the results of Schweitzer et al.^{9,10} who reported that γ_0 increased from 3.1×10^{-5} to 4.5×10^{-3} as the iodide concentration increased from 10^{-4} M to 10^{-2} M at 275 K.

The uptake of ClNO_2 on solutions of NaCl is much slower than on NaBr or NaI solutions. Behnke et al.¹ reported uptake of ClNO_2 at 291 K using a wetted wall flow tube, with uptake coefficients decreasing as the NaCl concentration increased. At 0.1 M NaCl, $\gamma_0 = (3.1 \pm 0.3) \times 10^{-6}$ but at 4.6 M NaCl, the value was about an order of magnitude smaller, $\gamma_0 = (0.27 \pm 0.02) \times 10^{-6}$. They proposed that this was due to the common ion effect owing to the reversible hydrolysis of ClNO_2 to $\text{Cl}^- + \text{NO}_2^+$.

Roberts et al.⁸ report that ClNO_2 produces Cl_2 when exposed to solutions of chloride with concentrations as low as 0.05 M, when the pH is less than 2.

- 91. ClONO₂ + H₂O(s).** Measurement of $\gamma = 0.3 (+0.7, -0.1)$ (Hanson and Ravishankara⁵) significantly exceeds early measurements of Molina et al.,¹¹ Tolbert et al.,¹⁴ Leu,⁹ and Moore et al.¹² but agrees reasonably well with subsequent measurements by Chu et al.,² Zhang et al.,¹⁵ and Fernandez et al.³ when geometrical surface areas are assumed for analysis. Previous measurements were probably complicated by NAT formation on the surface (Hanson and Ravishankara⁶ and Chu et al.²). Lower levels of ClONO₂(g) used by Hanson and Ravishankara⁵ minimized this surface saturation problem. Also, using lower ClONO₂ concentrations, Zhang et al. obtained a reaction probability of 0.08 ± 0.02 at 195 K, Fernandez et al. measured 0.1, and values were 0.03 to 0.13 from Chu et al. Subsequent Knudsen cell measurements at 180 and 200 K by Oppliger et al.¹³ showed initial uptake γ s in the 0.2 to 0.4 range. Measured reaction products were HNO₃ and HOCl. All of the HNO₃ and much of the HOCl is retained on the surface under polar stratospheric conditions (Hanson and Ravishankara^{5,6}). Hanson⁴ deposited ClONO₂ on H₂¹⁸O enriched ice and detected H¹⁸OCl showing the Cl-ONO₂ bond is broken at 191 K.

Data plots confirm a trend showing that at a high density of ClONO₂, the product HNO₃ covers the ice surface preventing the further reaction of ClONO₂ with H₂O molecules on the surface. Therefore, data obtained at high ClONO₂ densities ($>10^{14}$ molecules/cm³) are excluded from further evaluation. An experiment (Berland et al.¹) using a laser-induced thermal desorption technique yielded a much lower value of ClONO₂ reaction probability at 190 K (about 3 orders of magnitude lower) after extrapolating the results obtained at temperatures of 140 K and below. We also exclude this point in the averaging of data since the physical characteristics of ice surfaces at these very low temperatures may not be very representative of those found at stratospheric temperatures. Selected data show no temperature dependence between $T = 180$ and 200 K and averaged $\gamma_0 = 0.28 \pm 0.25$. Again, within the experimental accuracy, the Hanson and Ravishankara^{6,7} and Chu et al.² data show that uptake measurements are nearly independent of ice substrate thickness. See Henson et al.⁸ for discussion of a model which accounts for the effect of HNO₃ on the reaction ClONO₂ on water and nitric acid ice surfaces. The reactivity of ClONO₂ on ice, as modeled with high level ab initio methods and simulations with four water molecules is consistent with the above laboratory results, i.e., the uptake coefficient is modeled to be close to 0.1 at 180 K with a strong negative temperature dependence (Loerting et al.¹⁰).

Zondlo et al.¹⁶ report the formation of a supercooled H₂O/HNO₃ liquid layer at 185 K as a reaction product, forming NAT or NAD only after decreasing the relative humidity below the ice frost point. This effect is similar to that resulting from the interaction of gaseous HNO₃ or N₂O₅ with the ice surface. These authors measured $\gamma = (3 \pm 2) \times 10^{-3}$ at 185 K for the reaction of ClONO₂ with this supercooled liquid layer.

- 93. ClONO₂ + HNO₃·nH₂O(s).** Hanson and Ravishankara³ report a γ value of 0.006 at 201 K for the ClONO₂ reaction with the water on NAT (HNO₃·nH₂O). However, these authors present re-analyzed and additional data with γ ≈ 0.001 at 191 K in Hanson and Ravishankara.^{4,5} Similar experiments (Moore et al.⁸ and Leu et al.⁷) report a larger value of 0.02 ± 0.01 which falls very rapidly as slight excesses of H₂O above the 3/1 H₂O/HNO₃ ratio for NAT are removed. In general, it is difficult to know that only NAT is formed when freezing from solution; it is likely that the high value reflects the reactivity on water ice that will form when the solution stoichiometry is water rich. They measured γ of less than 1 × 10⁻⁶ for slightly water-poor NAT surfaces. Abbatt and Molina¹ report γ values reaching 0.002 at 202 K and high RH. Hanson and Ravishankara⁴ reported that γ for this reaction increases by a factor of 4 as the surface temperature increases from 191 to 211 K. However, Knudsen cell measurements at 185 K by Barone et al.² reported γ = 0.004 at a relative humidity (RH) of 100%, rising to 0.007 near RH = 120%, indicating a possible mild negative temperature dependence when high RH values from this and other studies are compared. Excluding the JPL data,^{7,8} the other data obtained at high RH (~90%) were averaged, assuming no temperature dependence, to yield γ = 0.0043 ± 0.0021. The strong dependence on RH and the possible temperature dependence suggest that systematic error probably exceeds the calculated statistical error. Within the experimental accuracy, the data of Hanson and Ravishankara^{4,5} show that measured uptake coefficients are independent of ice substrate thickness. Barone et al. report very similar uptake coefficients

for nitric acid dihydrate (NAD) as for NAT as a function of RH at 202 K. See Henson et al.⁶ for discussion of a model which accounts for the effect of HNO₃ on the reaction of ClONO₂ on water and nitric acid ice surfaces.

94. ClONO₂ + H₂SO₄·nH₂O(l). Results from wetted-wall flow tube (Hanson and Ravishankara⁵) Knudsen cell reactor (Manion et al.⁶), aerosol flow tube (Hanson and Lovejoy³), and droplet train uptake (Robinson et al.⁷) experiments supplement older wetted-wall flow tube (Hanson and Ravishankara⁴) and Knudsen cell measurements (Rossi et al.⁸ and Tolbert et al.¹⁰). Although earlier Knudsen cell measurements probably suffered from surface saturation, more recent results compare well with those from other techniques. Saturation free results, available over a temperature range of 200–265 K and a H₂SO₄ concentration range of 39 to 75 wt%, were fit to a phenomenological model developed by Robinson et al.⁷ Measured γ values depend strongly on H₂SO₄ concentration and vary modestly with temperature, with a trend to somewhat higher values for the 210–220 K temperature range. The temperature-dependent uptake model takes into account the temperature and composition dependence of the effective Henry's Law constant, liquid phase diffusion coefficient, and the liquid phase hydrolysis rate constant. The hydrolysis reaction was treated by modeling two reaction channels, a direct hydrolysis process dominating reaction at low H₂SO₄ concentrations with a reaction rate proportional to water activity and a proton-catalyzed reaction with a rate proportional to H⁺ activity, which dominates at higher acid concentrations.

The data fit to the original Robinson et al. model have been supplemented by additional wetted-wall flow tube and aerosol flow tube data from Hanson² and aerosol flow tube data from Ball et al.¹ A revised kinetic model (Shi et al.⁹) incorporating these data has been developed that is based on the earlier work of Robinson et al.⁷ In this model, γ is calculated using the expression

$$\frac{1}{\gamma} = \frac{1}{\alpha} + \frac{1}{\Gamma_b^{H_2O}}$$

where,

$$\Gamma_b^{H_2O} = \frac{4H_{ClONO_2}RT}{\bar{c}} \left(D_{ClONO_2} k_{hydr} \right)^{1/2}$$

The detailed parameterizations for H_{ClONO_2} , D_{ClONO_2} , and k_{hydr} are given in the Appendix in Shi et al.⁹ As was the case for N₂O₅ hydrolysis k_{hydr} is seen to have a direct and an acid catalyzed channel. Using the same error analysis approach as in the note on N₂O₅ uptake, the model error is about 32.4% (1 σ), with σ_m = 32.2% and σ_d = 4.0%.

In the calculation of the chlorine activation (Cl_2 production) rate under stratospheric conditions, one needs to take into account the competition between the reactions of $\text{ClONO}_2 + \text{H}_2\text{O}$ and $\text{ClONO}_2 + \text{HCl}$. The presence of HCl will depress the reaction probability of ClONO_2 with H_2O .

95. **$\text{ClONO}_2 + \text{H}_2\text{SO}_4 \cdot \text{H}_2\text{O}(\text{s})$ and $\text{H}_2\text{SO}_4 \cdot 4\text{H}_2\text{O}(\text{s})$.** Measurements by Hanson and Ravishankara¹ and Zhang et al.² demonstrate that the reaction probability on the tetrahydrate is a strong function of both temperature and relative humidity, both of which affect the level of adsorbed H_2O . Both groups covered the temperature range of 192–205 K. The reaction is slowest at higher temperatures and lower relative humidities. Zhang et al.² have parameterized their data in the form of $\log \gamma = a_1 + a_2 \log x + a_3 \log^2 x$; for 195 K and x = water partial pressure in Torr: $a_1 = 10.12$, $a_2 = 5.75$ and $a_3 = 0.62$; for a water partial pressure of 3.4×10^{-4} Torr and $x = T(\text{K})$ between 182 and 206: $a_1 = 318.67$, $a_2 = -3.13$ and $a_3 = 0.0076$. Zhang et al.³ have also measured a low value of $\gamma \sim 2 \times 10^{-4}$ on sulfuric acid monohydrate at 195 K.

- (2) Zhang, R.; Jayne, J. T.; Molina, M. J. Heterogeneous interactions of ClONO_2 and HCl with sulfuric acid tetrahydrate: Implications for the stratosphere. *J. Phys. Chem.* **1994**, 98, 867-874, doi:10.1021/j100054a022.
- (3) Zhang, R.; Leu, M.-T.; Keyser, L. F. Sulfuric acid monohydrate: Formation and heterogeneous chemistry in the stratosphere. *J. Geophys. Res.* **1995**, 100, 18,845-18,854.

96. **$\text{ClONO}_2 + \text{HCl} + \text{H}_2\text{O}(\text{s})$.** Reaction probabilities of 0.27 (+0.73, -0.13) (Leu⁶) and 0.05 to 0.1 (Molina et al.⁸) were reported at 195 and 185 K, respectively. Abbatt and Molina¹ and Hanson and Ravishankara⁴ report that a portion of the reaction may be due to $\text{HOCl} + \text{HCl} \rightarrow \text{Cl}_2 + \text{H}_2\text{O}$, with HOCl formed from $\text{ClONO}_2 + \text{H}_2\text{O}(\text{s}) \rightarrow \text{HOCl} + \text{HNO}_3(\text{s})$. Hanson and Ravishankara⁵ saw no enhancement of the ClONO_2 reaction probability when $\text{H}_2\text{O}(\text{s})$ is doped with HCl . Their preferred value at 192 K is $\gamma = 0.3$, but this is consistent with $\gamma = 1$. Chu et al.² also report a value of 0.27 (± 0.19) at 188 K, assuming no correction for porosity, but suggest the true value is 0.10 (± 0.08). Using a Knudsen cell technique and looking at initial uptake, Oppliger et al.⁹ measured $\gamma = 0.7$ at 180 K and 0.2 at 200 K with HCl in excess, and both Fernandez et al.³ and McNeil et al.⁷ report a value of >0.1 at close to 200 K. McNeil et al. report that this value is

substantially smaller at 218 K. Eliminating the Molina et al. points, which were taken at much higher ClONO₂ concentrations than the others, plots of the remaining data show no obvious bias when plotted as a function of reactant concentration or temperature (180–200 K). Their average value $\gamma = 0.26 \pm 0.06$. The Oppliger et al. data were presented for two HCl concentrations, differing by a factor of three. All points from both HCl concentrations were included since all the data were generally consistent with previous measurements, although the higher HCl concentrations did tend to produce modestly higher uptake coefficients. Until a fuller model is available, a single temperature independent value with a moderate uncertainty due to surface porosity seems appropriate.

97. **ClONO₂ + HCl + HNO₃•3H₂O.** Measurements by Hanson and Ravishankara,^{3,4} Leu and co-workers in Moore et al.⁶ and Leu et al.,⁵ and Abbatt and Molina¹ all report high γ values (>0.1) on NAT for temperatures between 192 and 202 K on water-rich NAT. Hanson and Ravishankara indicate that reaction probabilities on NAD are similar to those on NAT. The most recent NAT studies (Abbatt and Molina¹) show a strong fall-off with relative humidity from $\gamma > 0.2$ at 90% RH to 0.002 at 20% RH, indicating the necessity of sufficient water to solvate reactants. Within the limited measurements, data plots show no indication that the reaction probability of ClONO₂ + HCl depends on HCl and ClONO₂ gas phase concentrations or temperature between 191 and 202 K for water-rich NAT, but for nitric acid-rich NAT, there is a strong dependence on the partial pressure of HCl indicating that HCl is a limiting reagent on the surface under those conditions (Abbatt and Molina¹). Averaged data yield $\gamma = 0.23 \pm 0.10$ for the water-rich case. Carslaw and Peter² have published a model of this reaction and its dependence on HCl uptake.

98. **ClONO₂ + HCl + H₂SO₄•nH₂O(l).** Early work by Tolbert et al.¹⁰ and Hanson and Ravishankara⁴ indicated that the presence of HCl had little effect on the reaction of ClONO₂ with concentrated sulfuric acid (>65 wt% H₂SO₄). Subsequent realization that HCl would be more soluble, and therefore a more potent reactant, in the colder, more dilute sulfuric acid aerosols characteristic of the polar stratosphere led to additional investigations by Hanson and Ravishankara,⁵ Zhang et al.,¹¹ Elrod et al.,¹ and Hanson.² All these measurements show a strong dependence of reactivity on HCl solubility, which in turn depends on water activity. The solubility of HCl in a wide range of sulfuric acid solutions has been experimentally determined by a range of techniques that agree well with current thermodynamic models. See Robinson et al.⁸ for a review. Hanson and Lovejoy³ measured a reacto-diffusive length, *l*, of only 0.009 ± 0.005 μm for 60 wt% H₂SO₄ in an aerosol flow reactor. (See Hanson et al.⁶ for a definition of *l*) This is a factor of four lower than the value for the hydrolysis reaction of ClONO₂ showing the significant enhancement of ClONO₂ uptake due to HCl.

The ClONO₂ + HCl reaction on/in sulfuric acid has been modeled in Shi et al.⁹ using the same phenomenological model for ClONO₂ hydrolysis driven uptake by sulfuric acid. Since the effect of HCl on the ClONO₂ uptake is to increase the ClONO₂ pseudo-first-order reaction rate, the model of ClONO₂ uptake (see note on ClONO₂ uptake on sulfuric acid) should include the pseudo first order reaction rate, *k*_{HCl}. The formulation of *k*_{HCl} is found in the appendix in Shi et al.⁹ It is likely that the ClONO₂ reaction with HCl, like the ClONO₂ hydrolysis reaction, is acid catalyzed via protonated HClONO₂⁺, where Cl⁺ is activated as in the case of HOCl + HCl. For the ClONO₂ + HCl reaction, there is also a surface reaction (Hanson²). Hanson proposed that Γ_s, the effective uptake rate due to surface reactions, is linearly proportional to water activity; however, the calculated value of γ_o at 250 K and 60 wt% H₂SO₄ using his formulation is 0.02 (here γ_o~Γ_s), which is contradictory to his aerosol flow reactor result, which yielded γ_o = 0.0079 (here γ_o~Γ_b) (Hanson and Lovejoy³). In the model presented in the Shi et al. appendix, it is assumed that that Γ_s is linearly proportional to Henry's law constant of ClONO₂, rather than the water activity. The temperature dependence of Γ_s is determined, based on two measured values of Γ_s at 203 K (Hanson²) and 250 K (Hanson and Lovejoy³). The model yields a value of γ_o~0.011 (here γ_o~Γ_s), which is close to the measured value.

In the stratosphere, when the reaction rate of ClONO₂ with HCl exceeds the flux of HCl to the particle surface, HCl is depleted. This, in turn, will depress the rate of both the ClONO₂ and HOCl + HCl reactions, and increase the ClONO₂ hydrolysis rate. Shi et al.⁹ have proposed a model in which this effect is taken into account by including a factor *F*_{HCl} (see Table A–3 in Shi et al.). The formulation of *F*_{HCl} is based on scaling HCl reaction and accommodation fluxes. This flux correction is not exact (i.e., it does not rigorously calculate the HCl surface or bulk concentration) but provides a good approximation to the expected reduction in HCl + ClONO₂/HOCl reactivity and, just as importantly, the effective increase in ClONO₂ + H₂O reactivity when *p*_{ClONO₂} > *p*_{HCl}. This is particularly relevant during cold Cl activation events when HCl can be removed almost completely (i.e., see Jaegle et al.⁷).

Using the same error analysis approach as in the note on N₂O₅ uptake by sulfuric acid, the error of using the model in the Appendix is about 40.0% (one sigma), with σ_m = 39.8% and σ_d = 4.0%.

- 99. ClONO₂+HCl + H₂SO₄•H₂O(s) and H₂SO₄•4H₂O(s).** This reaction has been studied by Hanson and Ravishankara¹ and Zhang et al.² The reaction probability is strongly dependent on the thermodynamic state of the SAT surface, which is controlled by the temperature and the water vapor partial pressure. At a water vapor pressure of 5.6×10^{-4} Torr the measured γ drops by over two orders of magnitude as the SAT surface temperature rises from 195 to 206 K. The results from the two groups are in qualitative agreement, but sample different H₂O and HCl partial pressures. Zhang et al. have parameterized their data as a function of water partial pressure (at 195 K) and temperature (both at an HCl partial pressure of 4 to 8×10^{-7} Torr) in the form $\log \gamma = a_1 + a_2 \log x + a_3 (\log x)^2$. For H₂O partial pressure, $a_1 = 5.25$, $a_2 = 1.91$, and $a_3 = 0.0$; for T(K), $a_1 = 175.74$, $a_2 = -1.59$, and $a_3 = 0.0035$. Care must be taken in extrapolating either data set to lower HCl concentrations. Zhang et al.³ measured no enhancement of ClONO₂ uptake on sulfuric acid monohydrate at 195 K with $(2-8) \times 10^{-7}$ Torr of HCl present, implying $\gamma < 1 \times 10^{-4}$.

- 100. ClONO₂ + HCl + Al₂O₃(s).** Molina et al.¹ used flow tube techniques to measure $\gamma = 0.020 \pm 0.005$ on α -alumina at 195–230 K with stratospheric (5 ppmV) water vapor levels. Measured γ was independent of T and was affected very little by 5 ppbv HNO₃ vapor. The same γ was measured for a Pyrex surface, indicating the absorbed water and not the inorganic substrate hosted the reaction.

- 101. ClONO₂ + NaCl.** Timonen et al.¹⁰ studied the uptake of ClONO₂ on NaCl powders at 296 K and 225 K using a flow tube. Complete deactivation of the surface was observed at 225 K but not at 296 K. The uptake coefficients, after correction (typically by an order of magnitude) using the pore diffusion model of Keyser et al.^{7,8} were $\gamma_0 = (4.6 \pm 3.1) \times 10^{-3}$ (1 σ) at 296 K and $\gamma_0 = (6.7 \pm 3.2) \times 10^{-3}$ (1 σ) at 225 K. Similarly low values for the uptake coefficient are reported by Zelenov et al.¹¹ using a flow tube approach. On the other hand, Caloz et al.² used a Knudsen cell and found that the initial uptake coefficient was 0.23 ± 0.06 , independent of the type of salt used (powders, single crystals, deposited salt films) and without applying a correction for pore diffusion since no mass dependence for γ was observed; in similar studies. Aguzzi and Rossi¹ measured a value of $\gamma_0 = 0.10 \pm 0.05$ for the uptake of ClONO₂ on NaCl and 0.27 ± 0.10 for uptake on the unreactive NaNO₃ and Na₂SO₄ salts. The Cl₂ yield was 100% for NaCl, in agreement with the earlier studies^{2,10} but 27 ± 7 % on the unreactive salts. Koch and Rossi⁹ used a diffusion tube technique to measure a value of 0.1 for the uptake coefficient. Gebel and Finlayson-Pitts⁵

used a Knudsen cell and measured an initial value of $\gamma_0 = 0.14 \pm 0.11$ (2σ) and a steady-state value of $\gamma = (3.9 \pm 1.8) \times 10^{-2}$, but concluded that approximately two layers of salt were sampled in these multi-layer experiments. The use of a single or sub-single layer of NaCl gave a steady state value corrected using the model of Hoffman et al. of $\gamma = (2.4 \pm 1.2) \times 10^{-2}$.⁶ The source of the very disparate results from the different groups and techniques is not clear. All studies agree that the yield of Cl_2 is 100%, consistent with $\text{ClONO}_2 + \text{NaCl} \rightarrow \text{Cl}_2 + \text{NaNO}_3$ as observed earlier,⁴ with small amounts of HOCl from hydrolysis of ClONO_2 on the surface being observed in the presence of water.

Deiber et al.³ studied the uptake of ClONO_2 on water, NaCl and NaBr solutions using a droplet train flow reactor. The uptake coefficient was the same on water and 0.1 M NaCl, and Cl_2 was observed as the gas phase product.

102. ClONO_2 + KBr and NaBr. Caloz et al.² and Aguzzi and Rossi¹ report a rapid uptake of ClONO_2 on KBr solid salts at room temperature, $\gamma_0 = 0.35 \pm 0.06$ and $\gamma_0 = 0.18 \pm 0.07$ respectively; corrections for pore diffusion were not applied but are not expected to be large at these high uptake coefficients (see Introduction). This is consistent with a value of 0.1 measured by Koch and Rossi⁴ using a diffusion tube technique. The reaction products are BrCl, Br_2 and Cl_2 . BrCl is the initial reaction product formed from $\text{ClONO}_2 + \text{KBr} \rightarrow \text{BrCl} + \text{KNO}_3$. Br_2 is generated in a secondary reaction of BrCl with KBr: $\text{BrCl} + \text{KBr} \rightarrow \text{Br}_2 + \text{KCl}$. Cl_2 is then formed as the surface KBr is converted to KCl, which then reacts with ClONO_2 . Deiber et al.³ studied the uptake of ClONO_2 on water, NaCl and NaBr solutions using a droplet train flow reactor. On NaBr, the uptake increased from 0.041 at 0.01 M NaBr to 0.073 at 1 M NaBr. From the dependence on the NaBr concentration, a value for the mass accommodation coefficient for ClONO_2 of 0.108 ± 0.033 (2σ) was obtained. The gas phase products were BrCl and Br_2 , the latter formed by secondary reactions of BrCl with Br^- .

103. ClONO_2 + sea salt. Gebel and Finlayson-Pitts¹ reported a rapid reaction between ClONO_2 and synthetic sea salt, with initial values based on the geometric sample area of $\gamma_0 = 0.42$ and steady-state values of $\gamma = 0.16$ (2σ). These were measured with multiple salt layers (3–236) but corrections for diffusion into underlying layers for such high uptake coefficients are relatively small, less than a factor of three. The yield of Cl_2 was $78 \pm 13\%$; small amounts of HCl and HOCl were also observed as products. The recommended lower limit is based on these studies and the rapid uptake of other reactive species such as HNO_3 and N_2O_5 .

104. ClONO_2 + HBr + $\text{H}_2\text{O}(\text{s})$ and $\text{HNO}_3 \cdot n\text{H}_2\text{O}(\text{s})$. This reaction was studied by Hanson and Ravishankara² on water ice and NAT near 200 K. A diffusion-limited reaction probability of >0.3 was observed. Allan et al.¹ measured $\gamma = 0.56 \pm 0.11$ at 200 K on water ice, observing Cl_2 and Br_2 to be formed in yields of 100% and 66 to 80%, respectively, in the range 180 to 200 K.

- (1) Hanson, D. R.; Ravishankara, A. R. Heterogeneous chemistry of HBr and HF. *J. Phys. Chem.* **1992**, *96*, 9441-9446.

106. $\text{CF}_x\text{Cl}_{(4-x)}$ ($x=0-3$) and CF_2Br_2 + $\text{Al}_2\text{O}_3(\text{s})$. Robinson et al.³ reported steady-state dissociative uptake of CF_2Cl_2 and CF_2Br_2 on α -alumina surfaces at 210 and 315 K. Reaction probabilities of about 1×10^{-3} at 210 K were measured by monitoring the amounts of surface species bonded to the Al_2O_3 substrate. A re-analysis (Robinson et al.⁴) lowered this value by about a factor of 50. Moderate surface dosage with water vapor did not quench the reaction. In addition, Dai et al.¹ and Robinson et al.² studied dissociative chemisorption of CF_3Cl , CF_2Cl_2 , CFCl_3 , and CCl_4 on dehydroxylated γ -alumina powders. The obtained reactive uptake probabilities ranging from 0.4×10^{-5} for CFCl_3 to 1.0×10^{-5} for CF_2Cl_2 over a temperature range of 120 to 300 K. HCl and halomethyl radicals were observed as desorption products. Loss of these products may point to somewhat higher γ s, since they were measured by integrating halogen bound to Al_2O_3 substrates.

107. BrCl + NaCl, NaBr, KBr and NaI. The uptake of BrCl on solid NaCl and KBr using a Knudsen cell has been reported by Aguzzi and Rossi,¹ yielding 298 K values of 6×10^{-2} for NaCl and 0.14 on KBr. An earlier preliminary study from the same group reported a value at $\gamma > 0.1$ on KBr.² Insufficient data are available to make a recommendation.

Katrib et al.⁴ measured the uptake of BrCl on aqueous solutions of NaI over the temperature range from 273 to 288 K; the uptake coefficient increased from 0.37×10^{-2} to 0.7 as the I^- concentration increased from 1×10^{-4} to 0.5 M NaI. The complex dependence on the I^- concentration indicated that a surface reaction was occurring at the air-solution interface.

Huff and Abbatt³ studied the loss of BrCl on frozen bromide salt solutions at 233 K, finding that the uptake coefficients vary between 0.02 and 0.04 depending on the bromide concentration, independent of solution acidity.

108. Br₂ + NaCl, KBr and NaI. Only one report of the uptake of Br_2 on solid NaCl and KBr using a Knudsen cell is available¹ as part of a study of $BrONO_2$ uptake on salts. The uptake coefficient for Br_2 was 4×10^{-3} on NaCl and 3×10^{-3} on KBr. Insufficient data are available to make a recommendation.

Hu et al.² measured the uptake of Br_2 on aqueous solutions of NaI using a droplet train flow reactor over the temperature range of 263 to 293 K. The measured uptake coefficients decreased from 0.33 at 263 K to 0.08 at 293 K, with evidence for a significant contribution from a reaction at the interface between Br_2 and I^- .

- (2) Hu, J. H.; Shi, Q.; Davidovits, P.; Worsnop, D. R.; Zahniser, M. S.; Kolb, C. E. Reative uptake of $Cl_2(g)$ and $Br_2(g)$ by aqueous surfaces as a function of Br^- and I^- ion concentration: The effect of chemical reaction at the interface. *J. Phys. Chem.* **1995**, 99, 8768-8776, doi:10.1021/j100021a050.

109. BrO + H₂O(s), H₂SO₄•nH₂O(l) and NaCl(aq). Abbatt¹ used a coated flow tube technique to measure heterogeneous uptake on water ice, 60 and 70 wt% H_2SO_4 at 213 K, and 23 wt% aqueous NaCl at 253 K. He obtained $\gamma(ice) = (1.0 \pm 0.4) \times 10^{-3}$, $\gamma(60 \text{ wt\% } H_2SO_4) = (7 \pm 2) \times 10^{-4}$, $\gamma(70 \text{ wt\% } H_2SO_4) = (5 \pm 2) \times 10^{-4}$ and $\gamma(23 \text{ wt\% NaCl}) < 3 \times 10^{-3}$. He observed product Br_2 , indicating BrO self-reaction on both water ice and sulfuric acid solutions. Since reaction rate will depend on BrO concentrations, no recommendation is made for an atmospheric rate.

110. HOBr + H₂SO₄•nH₂O. Hanson¹ reported that uptake of HOBr on 80 wt.% H_2SO_4 , producing Br_2 . Br_2 and Br_2O production was also observed by Iraci et al.² during Knudsen cell studied of HOBr uptake on 70 wt% uptake for temperatures below 228 K. These products probably arise from HOBr self-reaction, although impurities in the acid solution might also play a role. Iraci et al. discuss methods to correct HOBr uptake

data for the effects of self-reaction and secondary reactions with its products. The bulk phase self-reaction of HOBr noted above is not likely to be significant over the expected range of atmospheric concentrations.

111. HOBr + HCl + H₂O(s). Abbatt¹ measured $\gamma = 0.25 (+0.10/-0.05)$ for this reaction on ice at 228 K. Chaix et al.³ measured $\gamma = 0.3$ on ice from 180 to 195 K, dropping to ~ 0.15 at 205 K. The BrCl product was observed by mass spectrometry. Allanic et al.² report a faster rate for this reaction than for HOBr uptake on pure ice (which had an uptake coefficient of 0.15 at 200 K). Mossinger et al.⁴ report a lower limit for γ of 0.1, under conditions with HCl concentration in excess of the HOBr concentration. No data on NAT surfaces is available.

112. HOBr + HCl + H₂SO₄•nH₂O. For the sulfuric acid reaction, Abbatt¹ measured γ s of ~ 0.1 to 0.2 for [HCl] $> 1 \times 10^{12} \text{ cm}^{-3}$ over 68.8 wt% H₂SO₄ at 228 K; yielding an estimated $k_{\text{HCl+HOBr}}^{\text{II}} = 1.4 \times 10^5 \text{ M}^{-1} \text{ s}^{-1}$ with a factor of 2 uncertainty. Hanson and Ravishankara³ also measured $\gamma \leq 0.2 (+0.2, -0.1)$ for 60 wt% H₂SO₄ at 210 K. However, both of these measurements were based on significant underestimation of the solubility of HOBr in the relevant sulfuric acid solutions. More recent measurements by Waschewsky and Abbatt⁵ indicate that the Henry's law constant for HOBr varies slightly with acidity between 60 to 70 wt% H₂SO₄ and more strongly with temperature between 208 and 238 K. (For 59.7 wt% H₂SO₄, $H (\text{M atm}^{-1}) = 1.2 \times 10^6$ at 208 K and 2.2×10^5 at 228 K.) The HOBr + HCl second order liquid phase rate constant, $k_{\text{HCl+HOBr}}^{\text{II}}$, varies between 2×10^5 and $3 \times 10^8 (\text{M}^{-1} \text{ s}^{-1})$ between 213 and 238 K over the same composition range (60–70 wt% H₂SO₄). Such a strong dependence on acid composition for the reaction rate of HOBr + HCl and the very small acid composition dependence for HOBr solubility in H₂SO₄ solution might be partially due to the formation of H₂OBr⁺ in the acidic solution as discussed in their paper. However, this acid catalyzed reaction, i.e. H₂OBr⁺ + HCl, alone does not completely account for measured reaction rates over the acid composition range studied.

Using the Henry's Law data for HOBr reported by Waschewsky and Abbatt,⁵ the limiting reagent will vary depending on atmospheric temperature (H₂SO₄ wt%) and the concentrations of HOBr and HCl. For stratospheric conditions where [HOBr] is 10 pptv and [HCl] 1 ppbv, they predict dissolved HOBr will be in excess above 204 K and HCl in excess below 204 K for a H₂O vapor partial pressure of $3 \times 10^{-7} \text{ atm}$. From their coated wall flow reactor uptake measurements, Waschewsky and Abbatt⁵ derived expressions for $k_{\text{HCl+HOBr}}^{\text{II}}$ and predicted uptake coefficients. For temperature between 204 and 218 K where HOBr is likely to be in excess, they calculated HCl uptake coefficients, γ_{HCl} , which range between 7×10^{-5} and 9×10^{-5} . For temperatures in the 202–198 K range, where dissolved HCl is likely to be excess, the calculated uptake coefficients for HOBr, γ_{HOBr} , of $\sim 1 \times 10^{-2}$. Hanson has reported Henry's law solubility data for 58–70 wt.% sulfuric acid and reactive uptake coefficients for HCl on HOBr doped sulfuric acid surfaces using a wetted wall flow reactor.² Hanson's reported that H_{HOBr} was independent of acid concentration at 250 K, however, the heat of solvation for HOBr derived is significantly lower (-12.5 ± 3.7 versus $-9 \pm 1 \text{ kcal/mol}$ reported at lower temperatures by Waschewsky and Abbatt) that the values of H^* based on Hanson's data, taken from 250 to 270 K, are much higher than the prior study's when extrapolated to their lower

temperatures. Hanson's reported γ_{HCl} are strongly dependent on HOBr partial pressure and drop almost three orders of magnitude as the sulfuric acid concentration is raised from 58 to 95 wt%, possibly because HCl may be reacting with sulfuric acid at higher acid concentrations. The higher temperature $k_{\text{HCl}+\text{HOBr}}^{\text{II}}$ values computed by Hanson for his data disagree, when extrapolated to lower temperatures with the values reported by Waschewsky and Abbatt as well as a prior lower temperature value reported by Hanson and Ravishankara.³ Better agreement can be obtained if the solvation enthalpy reported by Hanson is used to adjust the H_{HOBr} values used in the earlier, lower temperature studies. Clearly, the HOBr + HCl reaction will be difficult to parameterize in a simple manner. Potential inconsistencies in their $k_{\text{HCl}+\text{HOBr}}^{\text{II}}$ values, as discussed by Waschewsky and Abbatt⁵ and Hanson² indicate that further measurements are required before this reaction can be definitively modeled. Iraci et al.⁴ subsequently measured HOBr uptake over both of the temperature ranges covered in the prior experiments. Their derived H^* values agreed well with data from Waschewsky and Abbatt⁵ at lower temperatures but fell far below Hanson's higher temperature measurements. Thus, it appears that HOBr + HCl kinetic parameters developed from analyses based on the Hanson² data may need to be reanalyzed.

- 113. HOBr + HBr + H₂O(s) and H₂SO₄·nH₂O.** Abbatt¹ measured $\gamma = 0.12 \pm (0.03)$ on ice at 228 K. Chiax et al.³ measured γ_0 values ranging from 0.44 at 180 K to 0.15 at 205 K. The Br₂ product was observed by mass spectrometry. The HBr concentrations were such that the ice surface had probably melted. Abbatt² measured $\gamma = 0.25$ for $[\text{HBr}] = 1 \times 10^{12} \text{ cm}^{-3}$ over 68.8 wt% H₂SO₄ at 228 K; yielding an estimated $k_{\text{II}} > 5 \times 10^4 \text{ M}^{-1} \text{ s}^{-1}$.

- 114. HOBr + NaCl.** Studies have been done on solid salts and aqueous surfaces. On solids, Mochida et al.⁴ studied the uptake of HOBr on NaCl using multi-layer powders (10–500 μm) in a Knudsen cell at room temperature. After correction (by about an order of magnitude) for diffusion into the underlying layers, they obtained values for the initial uptake coefficient in the range of $(0.97\text{--}6.5) \times 10^{-3}$, with the corrected values decreasing with increasing concentrations of HOBr. They attributed this to competition between the reaction of HOBr with NaCl and a self-reaction of HOBr on the surface: $2 \text{HOBr} \rightarrow \text{Br}_2 + \text{H}_2\text{O} + \frac{1}{2} \text{O}_2$. Their final value of $\leq 6.5 \times 10^{-3}$ is based on their extrapolation back to very low HOBr concentrations. Both Br₂ and BrCl were observed as products. Chu et al.² measured the uptake of HOBr on NaCl at 250 K over a range of RH from 1.5 to 22.5%. After correcting the measured loss of HOBr by a factor of ~ 30 for diffusion into the underlying salt layers using the pore diffusion model, they obtained a value $\gamma_0 = 5 \times 10^{-5}$. The smaller value compared to the Knudsen cell results of Mochida et al.⁴ may be due to the much lower temperature they used; BrCl was the only gas phase product observed. Huff and Abbatt³ report reactivity with frozen NaCl solutions in a coated-wall flow tube at 233 K. Uptake coefficients were dependent on the

chloride concentration of the solution and on the acidity, with faster kinetics on the more acidic surfaces. BrCl was the only product observed.

Abbatt and Waschewsky¹ measured the uptake of HOBr on deliquesced 1–5 μm NaCl particles (75% RH); for particles at pH values of 0.3 and 7.2, a lower limit to the uptake coefficient of $\gamma_0 > 0.2$ was measured. On unbuffered particles, the upper limit for the uptake coefficient was $\gamma_0 < 1.5 \times 10^{-3}$ due to the limited availability of H^+ for the reaction between HOBr and Cl^- to form BrCl. Somewhat smaller values have been measured by Pratte and Rossi⁵ in another aerosol flow tube experiment, using acidified NaCl particles. Acidification was necessary for the reaction to be observable. In general, the uptake coefficients varied from 1 to 10×10^{-3} from 70 to 90% relative humidity. The particles were acidified with quite large amounts of H_2SO_4 , and the authors show that the reactivity on pure H_2SO_4 is less than that on the acidified salts. This could be a reason for the disagreement between the lower limit of Abbatt and Waschewsky and the Pratte and Rossi results.

- 115. HOBr + NaBr and KBr.** Mochida et al.⁶ studied the uptake of HOBr on solid KBr using multi-layer powders and spray-deposited films in a Knudsen cell. After correction (by factors of ~ 4 –5) for diffusion into the underlying layers for the powders, they obtained values for the initial uptake coefficient in the range of $(1.3\text{--}8.4) \times 10^{-2}$, with the corrected values again decreasing with increasing concentrations of HOBr due to the self-reaction of HOBr on the surface: $2 \text{HOBr} \rightarrow \text{Br}_2 + \text{H}_2\text{O} + \frac{1}{2} \text{O}_2$. On spray-deposited films where correction for diffusion into the underlying layers is not necessary, a value of 0.18 ± 0.04 was measured. The recommended upper limit is based on their extrapolation back to very low HOBr concentrations for the powders, and the spray-deposited film results. Br_2 was the only product observed. Chu et al.² measured the uptake of HOBr on NaBr at 250 K in a flow tube at RH from 0.5 to 12 %. After correction by approximately an order of magnitude for diffusion of HOBr into the underlying salt layers using a pore diffusion model, a value for γ_0 of 2.5×10^{-3} was obtained; the smaller value may be due to the much lower temperature at which these studies were carried out. Again, Br_2 was the only product observed.

The uptake of HOBr on aqueous solutions of NaBr has been measured by Wachsmuth et al.⁷ and by Fickert et al.³ Wachsmuth et al.⁷ report a rapid rate of uptake that is limited by mass accommodation; the mass accommodation coefficient was calculated to be 0.6 ± 0.2 . This is consistent with the studies of Fickert et al.³ who reported a lower limit for the mass accommodation coefficient of 1×10^{-2} at 274 K and observed that Br_2 was released at 100% yield at pH < 6.5. The yield of Br_2 decreased rapidly with pH at higher pH values due to the declining ratio of HOBr to BrO^- . Fickert et al.³ also measured the uptake of HOBr on aqueous solutions containing mixtures of NaCl and NaBr. BrCl was the major product at small Br^- concentrations while Br_2 dominated as the bromide ion concentration in solution increased.

Finally, there have been a number of coated-wall flow tube studies of HOBr reactivity on frozen salt solutions containing both NaCl and NaBr (Kirchner et al.,⁵ Huff and Abbatt,⁴ and Adams et al.¹). HOBr uptake coefficients are in the 10^{-2} to 10^{-3} range at roughly 233 K. A general finding is that if the HOBr concentrations are too high, then only BrCl is seen as a gas-phase product from films composed of the (low) seawater ratios of bromide to chloride. The reason for this is that the small concentrations of bromide at the surface are rapidly depleted, leaving only chloride available for reaction. However, for low

HOBr concentrations (10^9 to 10^{10} molecules/cm³), as used by Adams et al., Br₂ is observed as the initial product.

- 117. BrNO₂ + KCl and NaCl.** Caloz et al.¹ measured an uptake coefficient for BrNO₂ on KCl of 5×10^{-2} , but concluded that it was due only to reaction with a small bromide impurity in the KCl; as expected if this is the case, only Br₂ was generated in the reaction.

The uptake of BrNO₂ on aqueous solutions of 0.5 M NaCl has been measured using a droplet train flow reactor by Schweitzer et al.³ from 277–293 K yielding $\gamma_0 \sim 1 \times 10^{-5}$. Frenzel et al.² used a wetted wall flow tube to obtain a lower limit for the uptake coefficient of 3.8×10^{-5} at 291 K.

- 118. BrNO₂ + KBr, NaBr and NaI.** Caloz et al.¹ used a Knudsen cell to study the uptake of BrNO₂ on solid KBr powders. The uptake was fast, $\gamma_0 \geq 0.3$, with production of Br₂ as the gas phase product. On aqueous solutions of NaBr, the uptake coefficient increases as the concentration of NaBr increases.²⁻⁴ For example, at 278 K, γ_0 increased from 8.6×10^{-6} to 1.1×10^{-4} as the NaBr concentration increased from 5×10^{-4} to 5×10^{-2} , but was independent of temperature over the range from 275–293 K.⁴ The major gas phase product is Br₂, with smaller amounts of BrNO₂ and only at the smaller concentrations of NaBr.^{3,4}

The uptake of BrNO₂ on aqueous NaI solutions has been determined using a droplet train flow reactor³ and a wetted wall flow tube;⁴ the uptake coefficient from 4.4×10^{-5} to 4.4×10^{-4} as the iodide concentration increased from 10^{-4} M to 5×10^{-3} M.⁴

119. BrONO₂ and BrONO₂ + HCl + H₂O(s). Hanson and Ravishankara³ investigated these reactions in an ice-coated flow reactor at 200 (±10) K. The reaction of BrONO₂ with H₂O(s) proceeded at a rate indistinguishable from the gas phase diffusion limit, implying that the reaction probability may be as high as one; the product BrNO(g) was observed. Allan et al.² used a Knudsen cell reactor to measure BrONO₂ uptake between 190–200 K. Values of initial γ's in the 0.2–0.3 range were observed. An average γ = 0.26 ± 0.05 was obtained from all of the appropriate data from both experiments. Aguzzi and Rossi¹ studied the hydrolysis reaction on various types of ices, obtaining γ = 0.34 ± 0.03 at 180 K and γ = 0.15 ± 0.01 at 210 K. They observed HOBr as the main product and Br₂O as a secondary product. Hanson and Ravishankara³ also codeposited HCl with BrONO₂ observing rapid production of BrCl. It is unclear whether BrCl is produced directly from BrONO₂ + HCl or via HOBr (from BrONO₂ hydrolysis) reacting with HCl.

121. BrONO₂ and BrONO₂ + HCl + H₂SO₄·nH₂O(l). Hanson and co-workers used both coated flow tube and aerosol flow tube techniques to show that the reaction of BrONO₂ with 45–70 wt% H₂SO₄ is extremely facile at temperatures from 210 to 298 K. Hanson and Ravishankara² measured γs of 0.5 (+0.5, –0.25) (45 wt% H₂SO₄, 210 K), 0.4 (+0.6, –0.2) (60 wt%, 210 K), and 0.3 (+0.7, –0.1) (70 wt%, 220 K) in a coated-wall flow tube experiment. Hanson et al.,³ measured γ ~0.8 (20 to 40% error) for submicron aerosols at temperatures between 249 and 298 K and H₂SO₄ concentrations of 45 to 70 wt%; there was a sharp fall off in γ for H₂SO₄ concentrations between 73 and 83 wt%. Hanson also reported additional temperature dependent (230–295 K) coated flow reactor and room temperature (295–300 K) aerosol flow reactor studies extending measurements to higher acid wt% values.¹ Hanson has analyzed these combined data sets, the data indicated that γ is a function of sulfuric acid concentration, but independent of temperature. After eliminating one previously reported anomalously low 83 wt% data point Hanson has fit an empirical expression for measured γs for BrONO₂ + H₂O in the form of: 1/γ = 1/α + 1/γ_{rxn}, where γ_{rxn} = exp(a+b*wt.) and α = 0.80, and a = 29.2, b = –0.40.¹ Using the same approach as detailed in the note for N₂O₅ uptake on sulfuric acid, the error for BrONO₂ + H₂O is 27.3% (1σ), with γ_m = 26.6% and γ_d = 6.3%. Addition of excess HCl to 229 K, 40 and 60 wt% H₂SO₄ aerosols caused an increase in γ to 1.0 and 0.9, respectively.³

- 123. BrONO₂ + NaCl.** Aguzzi and Rossi¹ used a Knudsen cell and three types of NaCl samples (powders, spray-deposited and single crystal) to measure the uptake of BrONO₂ and obtained consistent results with $\gamma_0 = 0.31 \pm 0.12$. No correction for diffusion into the powders was made because of the high uptake coefficient (see Subsection 5.6). BrCl was the major product, $80 \pm 20\%$, with smaller amounts ($\sim 10\%$) of Br₂ and some HCl. Rapid uptake of BrONO₂ of the same magnitude was observed on the unreactive salts NaNO₃ and Na₂SO₄, with a Br₂ yield of $45 \pm 10\%$; this uptake and reaction was attributed to the self-reaction of BrONO₂ on the surface to generate Br₂O which decomposed to Br₂.
- Deiber et al.² studied the uptake of BrONO₂ on water, NaCl and NaBr solutions using a droplet train apparatus from 272–280 K. The uptake coefficient was the same on water and 0.1 M NaCl, where BrCl was observed as the gas phase product. On NaBr, the uptake increased with the square root of the NaBr concentration, from which a value for the mass accommodation coefficient for BrONO₂ of 0.063 ± 0.021 (2σ) was obtained.

- 124. BrONO₂ + KBr and NaBr.** Aguzzi and Rossi¹ used a Knudsen cell and three types of KBr samples (powders, spray-deposited and single crystal) to measure the uptake of BrONO₂ and obtained consistent results with $\gamma_0 = 0.33 \pm 0.12$. No correction for diffusion into the powders was made because of the high uptake coefficient (see Subsection 5.6). Br₂ was the major product, with its yield decreasing as the concentration of BrONO₂ increased; this was attributed to a competition between the reaction of BrONO₂ with KBr and the self-reaction of BrONO₂ on the surface.
- Deiber et al.² studied the uptake of BrONO₂ on water, NaCl and NaBr solutions using a droplet train flow reactor from 272–280 K. The uptake coefficient was the same on water and 0.1 M NaCl. On NaBr, the uptake increased with the square root of the NaBr concentration, from which a value for the mass accommodation coefficient for BrONO₂ of 0.063 ± 0.021 (2σ) was obtained. The gas phase product on the NaBr solution was Br₂.

- 125. ICl on NaCl/NaBr.** ICl uptake onto acidified and neutral NaCl/NaBr solutions at 274 to 298 K was studied in coated-wall flow tubes. The initial uptake coefficients were in the 0.6 to 3×10^{-3} range depending on the experimental system used, for solutions containing bromide; IBr was the gas-phase product observed. In an aerosol flow tube, uptake of ICl onto concentrated NaBr solutions showed uptake coefficients of 1 to 2×10^{-2} , which dropped to values of 10^{-4} on sea-salt solution aerosols. IBr was the product of the reaction on NaBr particles, with a yield of 0.6 (Braban et al.¹).

126. HOI on NaCl/NaBr. HOI uptake on acidified and neutral NaCl/NaBr solutions at 274 K in a wetted-wall flow tube indicate a lower limit for the uptake coefficient of 2.2×10^{-3} (Braban et al.¹). IBr is identified as the major gas-phase product when the solutions contain bromide to chloride ratios of 1:200, whereas ICl is the product from pure NaCl solutions. HOI uptake on dry and frozen solutions of NaCl and NaBr with chloride to bromide ratios equal to that of seawater were also studied in a coated wall-flow tube. The product ICl is only formed when the surface is depleted of bromide, otherwise IBr forms. Uptake coefficients measured in a flow reactor by Holmes et al.² are >0.01 at 243 K on the frozen films and >0.01 at 243 K and 298 K on dry salts. Mossinger and Cox³ report uptake of HOI onto dry films of NaCl, NaBr and sea salt from 278 to 298 K and measured uptake coefficients of 0.016, 0.034 and 0.061 respectively. The products are ICl, IBr and IC/IBr, respectively.

127. CF₃OH + H₂O + H₂O(l) and H₂SO₄•nH₂O(l). Lovejoy et al.¹ used both wetted-wall and aerosol flow tube techniques to measure reactive uptake of CF₃OH on water at 274 K and 39–60 wt% H₂SO₄ at various temperatures between 206 and 250 K. γ 's showed a strong dependence on water activity. Aerosol uptake studies yielded reacto-diffusive lengths of $>0.4 \mu\text{m}$ for 40 wt% H₂SO₄ and $1.0 \mu\text{m}$ for 50 wt% H₂SO₄, both at 250 K. Recommended γ 's were estimated by averaging bulk uptake measurements at similar H₂SO₄ concentrations and ignoring temperature effects on water activity.

128. SO₂ + O₃ + Al₂O₃(s). Usher et al.¹ present Knudsen cell data showing that pretreatment of α -alumina with SO₂ increases γ_0 values for O₃ uptake by 30%; FTIR observations by the same group show that O₃ oxidized surface sulfite and bisulfite formed by SO₂ absorption to sulfate and bisulfate.

129. SO₂ on H₂O₂/ice. SO₂ loss on ice surfaces has been observed to proceed when H₂O₂ is present, making the reaction of potential significance in ice clouds. Clegg and Abbatt² have observed this reaction when both SO₂ and H₂O₂ are delivered from the gas phase in a coated-wall flow tube at 228 K, with H₂O₂ in excess. For both SO₂ and H₂O₂ only small fractions of a monolayer are present on the surface during the reaction. It is inferred that the reaction proceeds through the HSO₃⁻ intermediate because the reaction rate declines as acidity builds up on the surface from the sulphuric acid product, i.e., because dissociation of adsorbed SO₂ to form HSO₃⁻ is becoming inhibited. At about 200 K, relative to the uptake on pure ice, Chu et al.¹ observe enhanced loss of SO₂ on ice films that have been doped with 3% H₂O₂ and they detect sulphate as a product. Uptake coefficients are reported in Clegg and Abbatt that are dependent on both the H₂O₂ and SO₂ partial pressure, so no single value prevails for atmospheric conditions.

130. SO₂ + H₂O₂, O₃, HONO, NO₂, HNO₃ + H₂SO₄•nH₂O(l). Rattigan et al.² used a bubble train reactor to measure the uptake of SO₂ in the presence of solvated oxidants at 293 K. For H₂O₂ the second order rate constant at 1 wt% H₂SO₄ agreed well with previous bulk kinetics measurements and with previous droplet train/flow reactor measurements. Measurements at 20, 40, and 60 wt% H₂SO₄ are the first reported for concentrated acid. Reaction rate data were fit to a two term (acid catalyzed and water catalyzed) bulk second order rate expression, which, in the limit of high acid activity ($a_{H^+} = \alpha_{H^+}[H^+]$, where α_{H^+} is the H⁺ activity coefficient) reduces to: $k_{H_2O_2}^{II} = 8.3 \times 10^4 (\alpha_{H_2O}/a_{H^+})$, where α_{H_2O} is the water activity coefficient. Both α_{H^+} and α_{H_2O} can be obtained from the sulfuric acid thermodynamic model of Carslaw et al.¹ The high a_{H^+} approximation for $k_{H_2O_2}^{II}$ should be accurate to a factor of two between 40 and 70 wt%. Uptake of SO₂ in the presence of solvated O₃ was measured for 1–70 wt% acid; the Henry's law expression for O₃ was determined in separate experiments. Measured second order rates agree reasonably well with previous results measured below 18 wt%. A three term fit for reaction with SO₂(aq), HSO₃[−], and SO₄[−] was fit to the data: $k_{O_3}^{II} = 6.6 \times 10^3 [SO_2(aq)] + 3.2 \times 10^5 [HSO_3^-] + 1 \times 10^9 [SO_4^-]$. This expression should be accurate to a factor of two between 20 and 70 wt%.

The HONO reaction was studied by adding nitrosyl sulfuric acid to 20, 40, 60, and 70 wt% acid. Measured second order rate constants were moderately consistent with previous measurements below 10 wt%. A $k_{HONO}^{II} = 142[H^+]$ was fit to the full data set; it should be accurate to a factor of two for acid concentrations between 10 and 70 wt%.

No enhanced SO₂ uptake was observed with added gas phase NO, NO₂, or with 20 wt% HNO₃ added to 50–60 wt% sulfuric acid.

131. SO₂ + Al₂O₃. Goodman et al.² used FTIR observations of SO₂ absorption on α-alumina to show that surface bound sulfite and bisulfite products are produced, they integrated these surface feature absorbencies to estimate a γ_0 of $(9.5 \pm 0.3) \times 10^{-5}$. Usher et al.⁸ performed BET corrected room temperature studies on four α-alumina samples reporting an average γ_0 of $(1.6 \pm 0.5) \times 10^{-4}$. Seisel et al.⁷ measured $\gamma_0 = (7.4 \pm 0.9) \times 10^{-3}$ on γ-alumina at 298 K using a pulsed Knudsen cell method. FTIR studies of SO₂ uptake on commercial γ-alumina catalyst samples also show sulfite formation on non-hydroxylated surfaces.^{1,3} Ma et al.⁶ co-deposited SO₂ and NO₂ on γ-alumina surfaces, using FTIR to observe that rather than forming adsorbed nitrite or nitrate, NO₂ dimerized and the dimer oxidized SO₂ to sulfate. Ma and coworkers⁴ extended their studies of NO₂/N₂O₄ interactions with adsorbed SO₂ on α-Al₂O₃, CaO, α-Fe₂O₃, ZnO₃, MgO, TiO₂ and SiO₂. Lo et al.⁵ published a density functional theory study of SO₂ interactions with hydrated and dehydrated γ-alumina surfaces calculating the thermochemistry of SO₂ adsorption and conversion to SO₃/HSO₃.

132. SO₂ + NaCl and sea salt. Gebel et al.¹ reported no measurable uptake of SO₂ on NaCl, yielding an upper limit of 1×10^{-4} for the uptake coefficient. The same was true for synthetic sea salt that had been heated while pumping. However, sea salt that had not been heated or pumped on extensively had a rapid uptake of SO₂, with initial uptake coefficients as large as 0.09. The time dependence of the uptake coefficient was consistent with uptake of SO₂ into a liquid layer, likely due to large amounts of water adsorbed on the hygroscopic components of sea salt such as magnesium hydrate. No gas phase products were observed but sulfite formation in the salt was seen by FTIR, indicating that uptake was due to dissolution of SO₂ into the water film on the salt surface.

133. SO₃ + H₂SO₄•nH₂O(l). Jayne et al.¹ measured the uptake coefficient in a wetted wall-flow reactor at 300 K over a composition range of 78–92 H₂SO₄ wt%. The measured γ was indistinguishable from 1.0. Higher water concentrations and lower temperatures probably tend to increase γ , so a value near 1.0 probably holds for all atmospheric conditions.

134. OCS + Al₂O₃. Liu and co-workers have measured OCS uptake on both α -alumina and γ -alumina surfaces at 298 K using Knudsen cell techniques³ and on α -alumina surfaces with controlled water vapor levels using both a Knudsen cell and a reaction chamber equipped with diffuse reflectance infrared Fourier transform spectroscopy (DRIFTS).⁴ The DRIFTS technique was also used to investigate heterogeneous reaction mechanisms, revealing that surface Al-OH plays a major role in oxidizing adsorbed OCS to CO₂ and that a number of surface adsorbed reactive intermediate anions, including HSCO₂⁻, are formed. The overall reaction is essentially a surface catalyzed hydrolysis reaction producing both CO₂ and H₂S.^{1,2,4} Liu et al.³ report uptake of relatively dry OCS yielding rather small $\gamma_0 = (4.9 \pm 0.5) \times 10^{-7}$ and $\gamma_{ss} = (6.5 \pm 2.4) \times 10^{-8}$ values for α -alumina and $\gamma_0 = (1.0 \pm 0.2) \times 10^{-7}$ and $\gamma_{ss} = (1.8 \pm 0.4) \times 10^{-8}$ values for γ -alumina at 298 K. The low steady-state uptake coefficients are probably due to consumption of most of the surface Al-OH sites and a low regeneration rate due to limited water vapor. OCS uptake experiments that provide controlled water vapor fluxes to α -alumina surfaces produce somewhat higher γ_{ss} values in the Knudsen apparatus, and the values obtained by integrating the DRIFTS spectra for RH values between 7 and 47% fall in the range of 7.4×10^{-6} to 3.3×10^{-6} .⁴ Interestingly, the highest uptake values are not obtained for the highest RH values because water vapor can also occupy reactive alumina surface sites and block OCS adsorption.

HO ₂ NO ₂	See Note	1 , 10
H ₂ O	See Note	1 , 11

5.16 Notes to Table 5-3

- See the discussions on soot presented in the introductory discussions of “Surface Types” and “Parameter Definitions” for descriptions of some of the factors affecting the uptake and reaction of gases on soot surfaces. In most cases, the available reactive surface area rather than the geometric areas have been used in obtaining the uptake coefficients; in those cases where the geometric area was used but a higher available surface area was involved in the measured uptake, the uptake coefficient is given as an upper limit. Most data are available at room temperature or there are very limited data at lower temperatures characteristic of the upper troposphere.

[Back to Table](#)

- SO₂ + soot.** $\gamma \leq 3 \times 10^{-3}$ measured using Degussa FW2 carbon black by Rogaski et al.⁷ This is an upper limit since it is based on the geometric surface area. Koehler et al.⁵ measured an average value of $(2 \pm 1) \times 10^{-3}$ over the first 10–30 s on n-hexane soot at –100° C (the initial uptake may be larger), but indicate that taking into account surface roughness would reduce this value. A number of studies¹⁻⁷ suggest that uptake is primarily due to physisorption on the surface; oxidation occurs in the presence of water, oxidants and metals.

- NH₃ + soot.** Chughtai et al.¹ and Muentert and Koehler² measured the uptake of NH₃ on soot. Based on Muentert and Koehler² where conditions are closest to atmospheric, NH₃ is not taken up by soot particles at temperatures above 173 K.

4. **O₃ + soot.** Many studies report a rapid, initial loss of O₃ followed by a slower loss that also occurs on aged soot or soot pre-exposed to ozone^{2,4-10,13,14,17,18}. Initial, rapid O₃ loss may be most applicable for soot as it comes out of aircraft exhaust, with $\gamma^{\text{init}} \sim 10^{-3}$ from most studies using both carbon black and organic combustion soots.^{6-8,13,18} The second stage of the reaction is probably more applicable to soot dispersed in air; $\gamma^{\text{aged}} \sim 10^{-4}$ – 10^{-6} using both carbon black and organic combustion soots,^{6-10,12,18} but in the range of 10^{-4} to 10^{-5} based on organic combustion soot data alone.^{8,10} A few studies have been carried out at temperatures below room temperature;^{2,8-10} given the wide ranges measured even at room temperature, these values generally fall in the same range. Il'in et al.⁸ report a temperature dependence for the initial uptake on fresh soot of $\gamma^{\text{fresh}} = 1.9 \times 10^{-3} \exp(-780/T)$ and for aged soots, $\gamma^{\text{aged}} = 1.8 \times 10^{-4} \exp(-1000/T)$. Both physisorption and reaction of ozone with the surface appear to take place. The studies of Fendel et al.⁶ suggest that lower particle growth in size below 40 ppb O₃ is due to less than a monolayer of O₃ on the surface. Stephens et al.¹⁸ proposed a Langmuir-type reversible adsorption of O₃, followed by a slower reaction with the surface. Pöschl et al.¹² proposed a similar scheme for uptake of ozone on spark-generated graphite soot coated with benzo[a]pyrene. Initial reversible physisorption occurred with $\gamma \sim 10^{-3}$, and “apparent reaction probabilities” for O₃ with BaP on soot of $\gamma \sim 10^{-5}$ – 10^{-6} were reported. The presence of water inhibited the reaction, which was postulated to be due to competitive adsorption between water and ozone on the surface; this is in contrast to the report of Chughtai et al.¹ in which the rate of ozone loss increased with RH. Pöschl et al.¹² report Langmuir adsorption equilibrium constants for O₃ and H₂O, and a second order surface reaction rate constant for the O₃-BaP reaction of $(2.6 \pm 0.8) \times 10^{-17} \text{ cm}^2 \text{ s}^{-1}$. Three possible paths have been proposed: (1) chemisorption of O₃; (2) catalytic decomposition of O₃: $2\text{O}_3 \rightarrow 3\text{O}_2$; (3) surface oxidation and formation of gas-phase carbon oxides. The studies of Fendel et al.⁶ suggest that lower particle growth in size below 40 ppb O₃ is due to less than a monolayer of O₃. Studies of Smith et al.¹⁷ and Smith and Chughtai¹⁴ suggest that catalytic decomposition occurs to some extent over the entire reaction sequence. CO₂ and H₂O are the major gas phase and surface oxidized functional groups on the surface such as carboxylic acids are observed.^{1-3,5,6,9,11,14-16,18}

5. **HNO₃ + soot.** Studies of the uptake of HNO₃ on soot have been carried out over a range of nitric acid pressures.¹⁻⁸ Measured values of γ at room temperature are typically in the range 10^{-1} – 10^{-5} , with smaller uptake coefficients measured at longer reaction times. Saathoff et al.⁷ report an upper limit of 3×10^{-7} as a time-averaged value over two days. At lower concentrations characteristic of the atmosphere, uptake appears to be primarily due to physisorption while at higher concentrations, $>2 \times 10^{12}$ molecule cm⁻³, a surface reaction occurs. At 220 K, $\gamma \sim 0.1$ with irreversible uptake attributed to reaction with surface groups.¹ Reaction of HNO₃ at concentrations from $(1-9) \times 10^{12}$ molecule cm⁻³ with “grey” soot from a rich flame using hexane has been reported⁸ to generate HONO as the major gaseous product with initial and steady-state reaction probabilities of $\gamma_o = 4.6 \times 10^{-3}$ and $\gamma_{ss} = 5.2 \times 10^{-4}$, respectively; reaction with “black” soot from a lean flame gave NO as the major gaseous product, with initial and steady-state reaction probabilities of $\gamma_o = 2.0 \times 10^{-2}$ and $\gamma_{ss} = 4.6 \times 10^{-3}$, respectively (based on geometric surface area of sample holder). The NO was hypothesized to result from secondary reactions of an initial HONO product.

6. **N₂O₅ + soot.** Brouwer et al.,¹ Longfellow et al.,² and Saathoff et al.³ studied the uptake of N₂O₅ at room temperature on a ground charcoal (carbon black) sample, on propane soot and on spark-generated graphite soot, respectively. Brouwer et al. and Longfellow et al. report uptake coefficients based on the geometric sample surface area, and therefore give upper limits. An upper limit of $\gamma \leq 0.02$ can be derived based on the

larger value of 0.016 reported by Longfellow et al. As discussed below, much smaller values are reported by Saathoff et al.: 4×10^{-5} under dry conditions and 2×10^{-4} at 50% RH. Three possible reactions may occur: (1) decomposition of N_2O_5 on the surface to generate $\text{NO}_2 + \text{NO}_3$; (2) reaction of N_2O_5 with the soot; (3) hydrolysis of N_2O_5 with water on the surface to generate HNO_3 . The studies of Longfellow et al. support the decomposition reaction, with yields of NO_2 within experimental error of 100%; the generation of NO_3 on the surface followed by its decomposition to NO_2 , may contribute to the observed production of NO_2 . The studies of Brouwer et al. suggest that a redox reaction with the soot surface to generate NO occurs in parallel with hydrolysis of N_2O_5 to generate HNO_3 . Saathoff et al. propose two independent, parallel reactions: (1) hydrolysis generating HNO_3 , $\text{N}_2\text{O}_5 + \text{soot} \rightarrow 2 \text{HNO}_3$ with $\gamma = (4 \pm 2) \times 10^{-5}$ under dry conditions (<10 ppm H_2O) which increases to $(2 \pm 1) \times 10^{-4}$ at 50% RH. (2) decomposition to NO and NO_2 : $\text{N}_2\text{O}_5 + \text{soot} \rightarrow \text{NO} + \text{NO}_2 + \text{products}$, with $\gamma = (4 \pm 2) \times 10^{-6}$ under dry conditions.

- (3) Saathoff, H.; Naumann, K.-H.; Riemer, N.; Kamm, S.; Möhler, O.; Schurath, U.; Vogel, H.; Vogel, B. The loss of NO_2 , HNO_3 , $\text{NO}_3/\text{N}_2\text{O}_5$, and $\text{HO}_2/\text{HOONO}_2$ on soot aerosol: A chamber and modeling study. *Geophys. Res. Lett.* **2001**, *28*, 1957-1960.

7. **$\text{NO}_2 + \text{soot}$.** A fast initial uptake of NO_2 is observed on fresh soots^{1-3,8-12,15,17,19,20,24-26} with the initial uptake coefficient in studies involving both carbon blacks and organic combustion soots in the range of $\gamma^{\text{init}} \cong 10^{-1}$ to 10^{-4} . For longer reaction times on carbon black soots, $\gamma^{\text{aged}} \sim 10^{-4}$ based on studies by Kalberer et al.¹⁶ and Ammann et al.^{3,4} However, Kleffmann et al.¹⁸ report a lower uptake coefficient of $\sim 10^{-7}$ on carbon black over the first 5 minutes of reaction and Saathoff et al.²¹ report an upper limit of $< 4 \times 10^{-8}$ averaged over 5 days under dry conditions (<10 ppm H_2O) on spark-generated graphite. On organic combustion soots, γ^{aged} has been reported to be in the range of $\sim 10^{-4}$ – 10^{-6} .^{1,4,5,19,22,24} All studies were done at room temperature except those of Longfellow et al.¹⁹ which were carried out at 262 K. The surface deactivates on continued exposure to NO_2 , suggesting a maximum amount of HONO that can be formed per cm^2 of soot area or mg of soot; this has been reported to be in the range of 10^{16} to 10^{18} HONO per mg of soot.^{5,12,14,15,18,24} However, reactivation on heating of the surface, exposure to water vapor and/or with time after the exposure is stopped has been observed.^{12,19,24-26} A small portion (~ 10 – 20%) of the NO_2 taken up appears to be chemisorbed to the surface.^{1,5,9,14,15,17,18,24-26} Infrared studies^{1,17,23} show that surface C–ONO, C–N– NO_2 , and C– NO_2 groups are formed. The remainder of NO_2 reacted appears as gaseous HONO and NO ; Salgado and Rossi²² report HONO as the major product for hexane soot from a flame at near stoichiometric ratio but NO as the major product for soot from an extremely lean flame. In addition, N_2O , CO , and CO_2 have been observed as products at higher temperatures.^{6,7} At lower NO_2 concentrations, the HONO yield can approach 100%; production of NO may be due to the bimolecular reaction of HONO on the surface at higher concentrations to give $\text{NO} + \text{NO}_2 + \text{H}_2\text{O}$. The HONO yield at 262 K appears to be smaller than at room temperature.¹⁹ Formation of HONO is due to reaction with a reduced surface site and not to NO_2 surface-catalyzed hydrolysis. The formation of HONO from the reaction of NO_2 with unspecified semi-volatile organics in diesel exhaust has been reported¹³ and proposed to be a much larger source of HONO than the reaction with the soot itself.

11. **H₂O + soot.** Alcalá-Jornod et al.¹ report an upper limit to the initial uptake coefficient of $\gamma < 2 \times 10^{-3}$, consistent with the earlier measurements of Rogaski et al.⁸ The uptake is most likely a reversible physisorption^{1,7} although based on water uptake isotherms, Chughtai et al.^{2,3,5,6} propose that at low relative humidities (<25%) chemisorption occurs. While prior exposure of Degussa FW-2 to NO₂ and SO₂ was not found to increase the uptake coefficient for water, treatment with HNO₃ increased the measured uptake coefficient by a factor of 28 and with H₂SO₄ by a factor of 68.⁸ Water adsorption isotherms on soot have been measured in a number of studies, e.g.²⁻⁶ and the amount of water taken up found to increase with the air/fuel ratio used to generate the soot, with the sulfur content, with aging and oxidation of the surface (e.g. by O₃) and with the presence of metals.^{2-6,9}

a. $\ln H = A + B/T + C \ln(T)$ [M atm⁻¹]

b. Uncertainty Classes:

I—Better than 10%

II—10% to 50%

III—50% to 100%

IV—Factor of 2 to factor of 10

V—Factor of 10 to factor of 100

VI—Greater than a factor of 100

c. $h_{G,0}$ and h_T are the gas-specific Sechenov coefficients. See section 5.10, Parameter Definitions, for more information.

5.18 Notes to Table 5-4

Note 1: Simple O, H Species

[Back to Table](#)

O₂	The recommendation was taken from the studies of Benson et al. ¹ and Rettich et al. ⁹ The data show clear curvature in a plot of $\ln(K_h)$ v. $1/T$. A two parameter fit gives $A = -13.26$ and $B = 1950$ K for the temperature range 273–285 K. The salt effect parameter $h_{G,0}$ is set to zero (see discussion in the text preceding this Table). The temperature dependent salt effect parameter is from the optimization of Weisenberger and Schumpe. ¹⁶
O₃	The recommendation of Rischbieter et al. ¹⁰ was accepted and refitted. Salt effect parameters were obtained from the effect of NaCl, KCl, Na ₂ SO ₄ , and Ca(NO ₃) ₂ on H, combined with specific ion parameters.
H	An average of estimates of the solubility of H based on two approaches: One is simply the assumption that the solubility of H is the same as the solubility of H ₂ . ⁸ The second assumes that the solubility of H is what would be expected for a rare gas atom of the same radius. ¹¹ The average value from 273 K to 298 K is 2.6×10^{-4} , with very small variation with temperature. Above room temperature the solubility increases.
OH	Calculated from the reduction potential of the OH radical, $E^\circ(\text{OH}/\text{OH}^-) = (1.90 \pm 0.02)$ V, derived from an equilibrium with Ti^+ . ¹³ This was combined with the Gibbs energy of the anion and the gas-phase radical to obtain the free energy of solution.
HO₂	The recommendation was based on a calculation by Schwartz ¹² based on the gas phase constituents HO ₂ , H ⁺ , and O ₂ ⁻ . Thermodynamic values were updated to those in our Thermodynamic tables, to $\text{p}K_a = (4.8 \pm 0.1)$, and to a reduction potential $E^\circ(\text{O}_2/\text{O}_2^-) = -(0.35 \pm 0.01)$ V. The reduction potential, referenced to one atmosphere O ₂ , is based primarily on equilibria reported by Meisel and Czapski, ⁶ corrected for a revised duroquinone potential. ¹⁵
H₂O₂	The data of Lind and Kok ⁴ (corrected), ⁵ Hwang and Dasgupta, ³ Yoshizumi et al., ¹⁷ Staffelback and Kok, ¹⁴ O'Sullivan et al., ⁷ and Huang and Chen ² are all in good agreement. The recommendation is from a two-parameter fit to all the results (Kok, et al. and Hwang and Dasgupta are represented by calculated endpoints; Huang and Chen by calculated points at the experimental temperatures). Previous recommendations were $A = -14.16$ and $B = 760$.

Note 2: Simple Inorganic Nitrogen Species

[Back to Table](#)

- N₂** The recommendation of Battino³ was accepted and refitted to three-parameter equations. A two parameter fit gives A = 12.81 and B = 1625 K for the temperature range 273–293 K. Salt effect parameters taken from the optimization of Weisberger and Schumpe.¹⁸
- NH₃** Based on the recommendation by Edwards et al.,⁹ refit to a two-parameter equation. Over the temperature range 273–348 K, there appears to be little curvature in the data. The more recent work of Dasgupta and Dong⁸ are in quite good agreement with this recommendation, whereas the results of Hales and Drewes¹⁰ are somewhat higher and those of Shi et al.¹⁶ (an uptake study) are significantly lower. The Hales and Drewes paper also included studies of the effect of dissolved CO₂ on the solubility of NH₃. The solubility of NH₃ in solutions containing a wide variety of ions is discussed by Clegg and Brimblecombe.⁷ Salt effect parameters taken from the optimization of Weisberger and Schumpe.¹⁸
- NF₃, N₂F₄** Refit to three- parameter equation from the recommendation of Wilhelm et al.¹⁹
- Chloramines**
Derived from flashoff studies with glass sparging columns at 20°C and 40°C.¹¹ Data point for ammonia at 20°C in exact agreement with recommended value in Table.
- NO** Three-parameter refit from the recommendation of Battino.² Two-parameter fit gives A = –12.27 and B = 1790 K for the temperature range 273–293 K. Salt effect parameters taken from the optimization of Weisberger and Schumpe.¹⁸
- NO₂** Based on NO₂ uptake studies and an analysis of literature values.⁶ A value of 0.014 was obtained from an analysis of studies of reactive dissolution of NO₂ by Schwartz and White.¹⁵
- NO₃** From the reduction potential $E^{\circ}(\text{NO}_3/\text{NO}_3^-) = (2.46 \pm 0.02) \text{ V}$, which is an average based on determinations of equilibria with Cl[–],^{5,12} combined with the Gibbs energy for the anion and the gas-phase radical. The derived solubility value is in good agreement with that calculated from the uptake of NO₃ into a wetted-wall flow reactor containing Cl[–].¹³ It is in very poor agreement with the much higher value derived from a study of the uptake of NO₃ by a series of wetted denuders.¹⁷
- N₂O** Three-parameter refit to the recommendation of Battino.¹ Two parameter fit gives A = 13.40 and B = 2880 K for the temperature range 273–293 K. Salt effect parameters taken from the optimization of Weisberger and Schumpe.¹⁸

- NOCl** Uptake kinetics measured as function of temperature into water and solutions containing HCl, NaCl, and NaOH. Only the latter had an effect. The kinetics were consistent with an uptake coefficient of 0.03.¹⁴
- HN₃** Measured using a packed column technique at pH 1.8 ($\mu = 0.02 \text{ mol L}^{-1}$). The effective Henry's law constant can be calculated using $K_H^* = K_H(1 + K_a/[H^+])$, with $pK_a = 4.65^4$

Note 3: Simple Inorganic Carbon Species[Back to Table](#)

- CO** The recommendation is based on smoothed data from Rettich et al.² and refit to three-parameter equation. A two parameter fit gives $A = -12.72$ and $B = 1720$ K for the temperature range 273–293 K.
- CO₂** Refit to three- parameter equation from the recommendation of Carroll et al.¹ Two parameter fit gives $A = -11.92$ and $B = 2550$ K for the temperature range 273–293 K. Salt effect parameters taken from the optimization of Weisberger and Schumpe.³

Note 4: Hydrocarbons[Back to Table](#)

- CH₄** The recommendation is a three-parameter fit to the smoothed recommendation of Battino.¹ There is very good agreement with the more recent data of Ben-Naim and Battino.² A two parameter fit gives $A = -13.45$ and $B = 2040$ K for the temperature range 273–293 K. Salt effect parameters taken from the optimization of Weisberger and Schumpe.⁴
- C₂H₆** The recommendation is a three-parameter fit to the smoothed recommendation of Battino.¹ There is very good agreement with the more recent data of Ben-Naim and Battino.² Two parameter fit gives $A = -15.95$ and $B = 2875$ K for the temperature range 273–293 K.
- C₃H₈** The recommendation is a three-parameter fit to the smoothed recommendation of Battino.¹ There is very good agreement with the more recent data of Ben-Naim and Battino.² A two parameter fit gives $A = 17.52$ and $B = 3275$ K for the temperature range 273–293 K. Salt effect parameters taken from the optimization of Weisberger and Schumpe.⁴
- n-C₄H₁₀** The recommendation is a three-parameter fit to the smoothed recommendation of Battino.¹ There is very good agreement with the more recent data of Ben-Naim and Battino.² A two parameter fit gives $A = -19.28$ and $B = 3740$ K for the temperature range 273–288 K. Salt effect parameters taken from the optimization of Weisberger and Schumpe.⁴
- CH₃CH(CH₃)CH₃** The recommendation is from a three-parameter fit to the smoothed recommendation of Battino.¹ A two parameter fit gives $A = 18.22$ and $B = 3340$ K for the temperature range 278–293 K.
- C₂H₄** The recommendation is from a three-parameter fit to the smoothed recommendation of Wilhelm.⁵ A two parameter fit gives $A = -12.40$ and $B = 2170$ K for the temperature range 288–313 K. Salt effect parameters taken from the optimization of Weisberger and Schumpe.⁴
- C₂H₂** Converted from the evaluation of Fogg et al.³ A two parameter fit gives $A = -10.70$ and $B = 2230$ for the temperature range 272–298 K. Previous recommendation was from a three-parameter fit to the recommendation of Wilhelm et al.⁵ The recommendation of Yaws et al.⁶ generates identical results.

Note 5: C1 Haloalkanes

[Back to Table](#)

CH₃F A refit to the evaluation of Staudinger and Roberts.⁵

CH₃Cl From the review of Warneck⁶ and in good agreement with the review cited previously.⁵ The uncertainties quoted are ± 0.47 in A and ± 139 in B. A more recent study over the temperature range 8–91°C is also in close agreement, with $K_h = 0.104$ vs. 0.131 M atm^{-1} at 293 K.³

CH₃Br, CH₃I

A refit to the evaluation of Staudinger and Roberts.⁵

CH₂Cl₂ From the review of Warneck.⁶ The review cited previously,⁵ gave somewhat different parameters, but a similar value at 298 K. The uncertainties quoted are ± 0.78 in A and ± 231 in B. A more recent study over the temperature range 8–91°C is also in close agreement, with $K_h = 0.401$ vs. 0.485 M atm^{-1} at 293 K.³

CHCl₃ From the review of Warneck.⁶ The review cited previously,⁵ gave somewhat different parameters, but a similar value at 298 K. The uncertainties quoted are ± 0.38 in A and ± 112 in B. A more recent study over the temperature range 8–91°C is also in close agreement, with $K_h = 0.313$ vs. 0.334 M atm^{-1} at 293 K.³

CHCl₂Br, CHClBr₂, CHBr₃, CF₂Cl₂, CFCl₃

A refit to the evaluation of Staudinger and Roberts.⁵

CCl₄ From the review of Warneck⁶ and in good agreement with the review cited previously.⁵ The uncertainties quoted are ± 0.40 in A and ± 119 in B. A more recent study over the temperature range 8–91°C is also in close agreement, with $K_h = 0.040$ vs. 0.046 M atm^{-1} at 293 K.³

CHF₃ Calculated values from the evaluation of Wilhelm⁷ were combined with results from Zheng et al.,⁸ double weighted. The latter study, gas solubilities measured at 278, 308, and 338 K and at NaCl concentrations from 0 to 0.0564 mole/mole (0 to 174%) with a gas absorption unit. Calculated values for 0% NaCl taken at each temperature and fitted to a two-parameter equation.

CHF₂Cl A linear fit to the data of Zheng et al.,⁸ Boggs and Buck,¹ and Kutsuna and Hori.⁴ The data of Chang and Criddle² were significantly lower than these results and not included in the fit. The review by Wilhelm, et al.⁷ gave a three-parameter fit that indicated curvature, but this does not appear to be supported by these more recent data.

CH₃OH The recommendation is from a three-parameter fit to the values derived through a comprehensive analysis of limiting activity coefficients, infinite-dilution partial molar excess enthalpies and heat capacities, and measured Henry's law constants.⁴ A two-parameter fit up to 298 K gives A = -13.61 and B = 5640, whereas a two-parameter fit up to 373 K gave A = -12.16 and B = 5215. An evaluation by Warneck¹⁰ for the temperature range 273 to 353 K resulted in recommended parameters of A = -12.45 and B = 5310. The previous recommendation was A = -12.08 and B = 5210, which was based on the two data points of Snider and Dawson.⁸ The 298 K result of Butler et al.³ and a calculation based on the NBS Thermodynamic tables,⁹ are in very good agreement. The 298 K result of Altschuh et al.¹ is about 40% lower.

C₂H₅OH The recommendation is from a three-parameter fit to the values derived through a comprehensive analysis of limiting activity coefficients, infinite-dilution partial molar excess enthalpies and heat capacities, and measured Henry's law constants.⁴ A two-parameter fit up to 298 K gives A = -17.14 and B = 6660, whereas a two-parameter fit up to 373 K gave A = -14.57 and B = 5908. An evaluation by Warneck¹⁰ for the temperature range 273 to 353 K resulted in recommended parameters of A = -15.87 and B = 6274. The previous recommendation was A = -16.98 and B = 6630, which was based on the two data points of Snider and Dawson,⁸ the 298 K results of Butler, et al.³ and Rohrschneider,⁷ and a calculation based on the NBS Thermodynamic tables,⁹ are in very good agreement. The 298 K result of Altschuh, et al.¹ is about 50% lower.

***n*-C₃H₇OH** The recommendation is from a three-parameter fit to the values derived through a comprehensive analysis of limiting activity coefficients, infinite-dilution partial molar excess enthalpies and heat capacities, and measured Henry's law constants.⁴ A two-parameter fit up to 298 K gives $A = -19.80$ and $B = 7370$. The previous recommendation was $A = -20.16$ and $B = 7470$, which was based on two data points from Snider and Dawson.⁸ Room temperature data from other studies¹⁻³ support these results.

***iso*-C₃H₇OH, 2-propanol**

The recommendation is from a three-parameter fit to the values derived through a comprehensive analysis of limiting activity coefficients, infinite-dilution partial molar excess enthalpies and heat capacities, and measured Henry's law constants.⁵ A two-parameter fit up to 298 K gives $A = -18.95$ and $B = 7100$. The previous recommendation was $A = -20.5$ and $B = 7450$, which was based on the two data points of Snider and Dawson⁸ supported by room temperature data from other studies.^{1,3}

***n*-C₄H₉OH** The recommendation is from a three-parameter fit to the values derived through a comprehensive analysis of limiting activity coefficients, infinite-dilution partial molar excess enthalpies and heat capacities, and measured Henry's law constants.⁴ A two-parameter fit up to 298 K gives $A = -17.68$ and $B = 6725$. The previous recommendation was $A = -19.34$ and $B = 72.10$, which was based on two data points from Snider and Dawson.⁸ Room temperature data from other studies^{1,2} support these results.

***iso*-C₄H₉OH, 2-methyl-1-propanol**

The recommendation is from a three-parameter fit to the values derived through a comprehensive analysis of limiting activity coefficients, infinite-dilution partial molar excess enthalpies and heat capacities, and measured Henry's law constants, over the temperature range 298–372 K.⁵ A two-parameter fit up to 298 K gives $A = -21.56$ and $B = 7720$. Extrapolated values are in very good agreement with the results of Snider and Dawson⁸ at 273 and 298 K and room temperature data from other studies.^{3,1} A room temperature value of 22.2 M atm⁻¹ from a thermal desorption-GC/MS study is about 40% lower than this recommendation.⁶

***sec*-C₄H₉OH, 2-butanol**

The recommendation is from a three-parameter fit to the values derived through a comprehensive analysis of limiting activity coefficients, infinite-dilution partial molar excess enthalpies and heat capacities, and measured Henry's law constants, over the temperature range 298–372 K.⁵ A two-parameter fit up to 298 K gives $A = -22.60$ and $B = 7095$. Extrapolated values are in very good agreement with the results of Snider and Dawson⁸ at 273 and 298 K and room temperature data from Butler et al.³

***tert*-C₄H₉OH, 2-methyl-2-propanol**

The recommendation is from a three-parameter fit to the values derived through a comprehensive analysis of limiting activity coefficients, infinite-dilution partial molar excess enthalpies and heat capacities, and measured Henry's law constants, over the temperature range 298–372 K.⁵ Extrapolated values are in very good agreement with the results of Snider and Dawson⁸ at 273 and 298 K and room temperature data from Butler et al.³ The two data points of Snider and Dawson yield $A = -23.63$ and $B = 8310$.

Note 10: Polyols

[Back to Table](#)

HOCH₂CH(OH)CH₂OH, glycerol

The vapor pressure of the pure liquid and the activity coefficient of the dilute solution were determined from an analysis of literature data. These were then used to obtain the Henry's law value.¹

HOCH₂(CH(OH))₂CH₂OH, erythritol

Determined from the solubility, water activity, obtained by a review of the literature, and solid vapor pressure of the polyol.¹

C₅H₈(OH)₄, pentaerythritol

Determined from the solubility, water activity, obtained by a review of the literature, and solid vapor pressure of the polyol.¹

C₅H₇(OH)₅, xylitol, adonitol, arabitol

Determined from the solubility, water activity, obtained by a review of the literature, and solid vapor pressure of the polyols stereoisomers.¹ These values, xylitol (4.0×10^{13}), adonitol (4.7×10^{13}), and arabitol (6.8×10^{13}) were averaged to get the value in the Table.

C₆H₈(OH)₆, sorbitol, mannitol, glactitol

Determined from the solubility, water activity, obtained by a review of the literature, and solid vapor pressure of the polyols stereoisomers.¹ These values, sorbitol (6.7×10^{16}), mannitol (1.8×10^{17}), and glactitol (9.1×10^{16}) were averaged to get the value in the Table.

Note 13: Aldehydes[Back to Table](#)

HCHO The recommended value is the apparent Henry's law constant and includes a contribution due to hydrolysis $H^* = H(1 + K_{hyd})$. Data from Betterton and Hoffmann³ and Zhou and Mopper⁹ are in substantial agreement and were fit to a two-parameter expression. The more recent results of Allou et al.¹ are in complete agreement. Betterton and Hoffmann have calculated $H = 2.5 \text{ M atm}^{-1}$ at 298 K for the physical solubility. A gas-stripping study over the temperature range 5–50 °C agreed at room temperature, but was lower below and higher above room temperature.⁷ Salt effect parameters derived from data on the effect of seawater concentration (0 to 100%) on the measured H .⁹ For these calculations, the seawater was assumed to be a solution of pure NaCl, with 35‰ salinity equal to 0.6 M. Additional studies of the effect of NaCl as a function of temperature have been carried out by Allou et al.¹

CH₃CHO The recommended value is the apparent Henry's law constant and includes a contribution due to hydrolysis $H^* = H(1 + K_{hyd})$. The results of Snider and Dawson,⁸ Benkelberg et al.,² and Betterton and Hoffmann³ are in excellent agreement and have been fit to a two-parameter expression for the recommendation. The results of Zhou and Mopper⁹ curve off at higher temperatures and were not included in the fit. (Note the similar situation for acetone.) Betterton and Hoffmann³ have calculated $H = 4.8 \text{ M atm}^{-1}$ at 298 K for the physical solubility. Salt effect parameters derived from data on the effect of seawater concentration (0 to 100%) on

the measured H .⁹ For these calculations, the seawater was assumed to be a solution of pure NaCl, with 35‰ salinity equal to 0.6 M.

C₂H₅CHO Results of Zhou and Mopper⁹ and Snider and Dawson⁸ agree only to within about a factor of two. The two points from the former were weighted by 3 and combined with the five points of the latter to generate the recommendation. A room temperature value of 9.26 M atm⁻¹ from a thermal desorption-GC/MS study is in good agreement with this recommendation.⁶ Salt effect parameters derived from data on the effect of seawater concentration (0 to 100%) on the measured H .⁹ For these calculations, the seawater was assumed to be a solution of pure NaCl, with 35‰ salinity equal to 0.6 M.

C₃H₇CHO The results from Zhou and Mopper⁹ were fit to a two-parameter expression. A room temperature value of 6.19 M atm⁻¹ from a thermal desorption-GC/MS study is about 40% lower than this recommendation.⁶ Salt effect parameters derived from data on the effect of seawater concentration (0 to 100%) on the measured H .⁹ For these calculations, the seawater was assumed to be a solution of pure NaCl, with 35‰ salinity equal to 0.6 M.

CHOCHO, glyoxal

Measured using a bubble-column method.⁴ Validation measurements on formaldehyde and acetic acid gave results of 4.8×10^3 and 5.0×10^3 , slightly higher than the recommendations here. The recommended value is the apparent Henry's law constant and includes a contribution due to hydrolysis $H^* = H(1 + K_{hyd})$. An intrinsic $K_h = 1.90 \text{ M atm}^{-1}$ was calculated at 298 K. The solubility increased by about a factor of three at 0.05 M NaCl, but dropped by ~50% when the concentration was increased to 5 M. Na₂SO₃ concentrations of 0.0003 M to 0.03 M increased the solubility, up to a factor of ~50. Even higher sulfate concentrations led to values too high to measure. An earlier study reported only limiting values of $\geq 3 \times 10^5$.³

HOCH₂CHO, hydroxyacetaldehyde

Apparent Henry's law measurements by a bubble-column technique at 25 and 45°C.³ An intrinsic Henry's law constant of $4.1 \times 10^3 \text{ M atm}^{-1}$ at 298 K was calculated.

CH₃C(O)CHO, methyl glyoxal

Apparent Henry's Law constant measured by a bubble-column technique.³ An intrinsic Henry's law constant of 1.4 M atm^{-1} at 298 K was calculated.

CH₂C(CH₃)CHO, methacrolein

Measured using a static technique with daily instrument calibrations and absolute determinations of partial pressures.⁵ An uncertainty of $\pm 0.7 \text{ M atm}^{-1}$ was reported.

Note 14: Ketones

[Back to Table](#)

CH₃COCH₃

The recommendation is from a fit to the data of Snider and Dawson,¹⁰ Benkelberg et al.,¹ Betterton,² and Strekowski and George.¹¹ Room temperature data points of Nozière and Riemer,⁸ Hoff et al.,⁵ Burnett,³ and Vitenberg et al.¹² are in very good agreement. Results of Zhou and Mopper¹³ are somewhat higher, particularly at room temperature and above. The situation is similar for acetaldehyde. Salt effect parameters derived from data on the effect of seawater concentration (0 to 100%) on the measured H .¹³ For these calculations, the seawater was assumed to be a solution of pure NaCl, with 35‰ salinity equal to 0.6 M. The K_S values from this work are somewhat different than those obtained by Benkelberg et al.,¹ 0.089 vs 0.17 at 298 K and 0.17 vs 0.085 at 273 K. The magnitude of this difference is not too great, but the two studies predict a different sign for h_T .

C₂H₅C(O)CH₃, butanone, methyl ethyl ketone

The recommendation is from the two points of Snider and Dawson.¹⁰ The room temperature points of Vitenberg et al.¹² and Rohrschneider⁹ are in good agreement, while a room temperature value of 10.5 M atm⁻¹ from a thermal desorption-GC/MS study⁷ is about 80% lower. The higher temperature data of Zhou and Mopper¹³ are somewhat higher and those of Friant and Suffet⁴ are lower than the recommendation. Salt effect parameters derived from data on the effect of seawater concentration (0 to 100%) on the measured H .¹³ For these calculations, the seawater was assumed to be a solution of pure NaCl, with 35‰ salinity equal to 0.6 M.

CH₃C(O)C(O)CH₃, 2,3-butanedione

Measured by a bubble-column technique.²

CH₂CHC(O)CH₃, methyl vinyl ketone

Measured using a static technique with daily instrument calibrations and absolute determinations of partial pressures.⁶ An uncertainty of ± 7 M atm⁻¹ was reported.

Note 15: C1 and C2 Organic Acids

[Back to Table](#)

HC(O)OH The results of Johnson et al.³ are accepted. The 298 K result of Khan et al.⁴ is about 75% lower.

CH₃C(O)OH

The results of Johnson et al.³ are accepted. A value calculated from the NBS Thermodynamic tables⁶ is about a factor of two higher.

HC(OH)C(O)OH, glycolic acid

Measured using a bubble-column method with no pH control (measured ~3–3.1).² Validation measurements on formaldehyde and acetic acid gave results of 4.8×10^3 and 5.0×10^3 , slightly higher than the recommendations in the Table. An intrinsic $K_h = 2.37 \times 10^4 \text{ M atm}^{-1}$ was calculated at 298 K.

HC(O)C(O)OH, glyoxylic acid

Measured using a bubble-column method with no pH control (measured ~2.6–2.8).² Validation measurements on formaldehyde and acetic acid gave results of 4.8×10^3 and 5.0×10^3 , slightly higher than the recommendations in the Table. An intrinsic $K_h = 28.67 \text{ M atm}^{-1}$ was calculated at 298 K.

CH₃C(O)C(O)OH, pyruvic acid

Taken from Khan et al.⁴ Salt effect derived from effect of NaCl ($k_s = 0.236 \text{ M}^{-1}$) and KCl ($k_s = 0.235 \text{ M}^{-1}$) on the partial pressure over 1.5 M solution of pyruvic acid at various salt concentrations. Much different values derived when other salts were used, suggesting complications due to specific interactions and, possibly, to the weakly buffered nature of the solution.

HOC(O)C(O)OH, oxalic acid

Determined from the solubility, water activity, obtained by a review of the literature, and solution vapor pressure of the acid.¹ The first two were obtained by a review of the literature; the vapor pressure was from evaporation measurements on levitated particles.⁵

Note 16: C₃ and Higher Organic Acids

[Back to Table](#)

HOC(O)CH₂C(O)OH, malonic acid

The solubility and water activity for the acid were obtained through a review of the literature. These were combined with solid vapor pressure¹ or solution vapor pressure⁴ data to derive Henry's law values of 0.94×10^{10} and 3.9×10^{10} M atm⁻¹.²

HOC(O)CH₂CH₂C(O)OH, succinic acid

The solubility and water activity for the acid were obtained through a review of the literature. These were combined with solid vapor pressure¹ or solution vapor pressure⁴ data to derive Henry's law values of 2.0×10^9 and 4.2×10^9 M atm⁻¹.²

HOC(O)(CHOH)₂C(O)OH, tartaric acid

Determined from the solubility, water activity, obtained by a review of the literature, and liquid vapor pressure of the acid.² The first two were obtained by a review of the literature; the vapor pressure was obtained from the evaporation rate of levitated, supersaturated liquid particles.³ The value listed is the midpoint of the range ($0.7\text{--}9.3 \times 10^{17}$) from the uncertainty in the vapor pressure data.

HOC(O)C₃H₆C(O)OH, glutaric acid

The solubility and water activity for the acid were obtained through a review of the literature. These were combined with solid vapor pressure¹ or solution vapor pressure⁴ data to derive Henry's law values of 2.4×10^9 and 5.2×10^9 M atm⁻¹.²

HOC(O)C₄H₈C(O)OH, adipic acid

Determined from the solubility, water activity, obtained by a review of the literature, and solid vapor pressure of the acid.² The first two were obtained by a review of the literature; the vapor pressure was from evaporation rates of aerosol samples.¹

(CH₂C(O)OH)₂C(OH)C(O)OH, citric acid

Determined from the solubility, water activity, obtained by a review of the literature, and liquid vapor pressure of the acid.² The first two were obtained by a review of the literature; the vapor pressure was obtained from the evaporation rate of levitated, supersaturated liquid particles.³ The value listed is the midpoint of the range ($0.2\text{--}6 \times 10^{17}$) from the uncertainty in the vapor pressure data.

Note 23: Nitro compounds

[Back to Table](#)

Nitroalkanes (CH₃NO₂, C₂H₅NO₂, C₃H₇NO₂, and CH₃CH(NO₂)CH₃)

The recommended values are all taken from the work of Benes and Dohnal.¹ For nitromethane, the 298 K value from Rohrschneider⁹ is about 30% higher.

Alkyl nitrates (CH₃ONO₂, C₂H₅ONO₂, 1-C₃H₇ONO₂, 2-C₃H₇ONO₂, 1-C₄H₉ONO₂, 2-C₄H₉ONO₂)

The recommended values are all taken from the work of Kames and Schurath.⁷ The results of Luke et al.⁸ are in very good agreement for 1-butyl and 2-butyl nitrates, but the values reported by Hauff⁴ for 1- and 2-propyl and butyl nitrates by head-space chromatography are significantly (~50%) lower.

CH₃C(O)O₂NO₂ (PAN)

The results of Kames and Schurath⁷ and Frenzel et al.³ are close and were used for the recommendation. They are somewhat higher (~60%) than the single temperature point of Holdren et al.⁵ Kames and Schurath⁷ and Holdren et al.⁵ also measured hydrolysis rate constants. $K_s = 0.0807 \text{ M}^{-1}$ for NaCl at 293.2 K based on solubility in artificial sea water (~0.7 M).⁷

Bifunctional alkyl nitrates

($\text{HOC}_2\text{H}_4\text{ONO}_2$, $\text{HOCH}_2\text{CH}(\text{ONO}_2)\text{CH}_3$, $\text{CH}_3\text{CH}(\text{OH})\text{CH}_2\text{ONO}_2$, $\text{CH}_3\text{C}(\text{O})\text{CH}_2\text{ONO}_2$)

The recommended values (at 293 K) are taken from the work of Kames and Schurath.⁶

 $\text{CH}_3\text{CH}(\text{ONO}_2)\text{CH}_2\text{ONO}_2$, 1,2-propane dinitrate

Direct measurement at 293 K.⁶ A much lower value of $33 \text{ atm}^{-1} \text{ L}^{-1} \text{ mol}$ was calculated from vapor pressure and solubility measurements.²

 $\text{O}_2\text{NO}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{ONO}_2$, 1,3-propane dinitrate

Calculated from vapor pressure and solubility measurements.² Note that the value for 1,2-propane dinitrate was much lower than that directly measured.

 CCl_3NO_2 , chloromethylnitrate (chloropicrin)

Measured by a stripping technique in water, 0.1 M and 0.2 M NaCl, and at pH 4.0 and 8.0 (buffered). All values were within the stated margin of error (± 0.3).¹⁰

Note 26: Haloaldehydes

[Back to Table](#)

CCl₃CHO 1,1,1-trichloroacetaldehyde (chloral). Apparent Henry's law constant measured by head-space analysis.¹ An intrinsic Henry's law constant of $14 \text{ mol L}^{-1} \text{ atm}^{-1}$ at 25°C was derived. Listed parameters from a refit to the data.

- (1) Betterton, E. A.; Hoffmann, M. R. Henry's law constants of some environmentally important aldehydes. *Environ. Sci. Technol.* **1988**, 22, 1415-1418.

Note 27: Haloacids

[Back to Table](#)

CFH₂C(O)OH

Equilibrium partial pressure of the acid obtained using a stripping technique over a solution containing 0.15 mol kg^{-1} HBr to suppress dissociation. Reported values corrected for the effect on the activity of the solution.¹ Due to high toxicity, only a single determination was made for this acid.

CF₂HC(O)OH

Equilibrium partial pressure of the acid obtained using a stripping technique over a solution containing 0.15 to 6.0 mol kg^{-1} HBr to suppress dissociation.¹ Reported values corrected for the effect on the activity of the solution.

CF₃C(O)OH, trifluoroacetic acid

Values derived at 178, 288, and 298 K from the simultaneous measurement of the equilibrium partial pressures of TFA over aqueous solutions and the concentration of undissociated TFA in solution using total reflection IR spectroscopy.² The previous recommended value from the equilibrium partial pressure of the acid obtained using a stripping technique over a solution containing HBr to suppress dissociation, assuming a pK_a value of 0.47 at 298 K.¹ The results of Kutsuna and Hori suggest a pK_a value of 0.2. It has been pointed out that are large discrepancies in reported pK_a values for TFA, which are not fully understood.³

CClH₂C(O)OH and CCl₂HC(O)OH

Equilibrium partial pressure of the acid obtained using a stripping technique over a solution containing 0.15 to 6.0 mol kg^{-1} HBr to suppress dissociation. Reported values corrected for the effect on the activity of the solution.¹

CCl₃C(O)OH

Equilibrium partial pressure of the acid obtained using a stripping technique over a solution containing 0.25 to 6.0 mol kg⁻¹ HBr to suppress dissociation. Reported values corrected for the effect on the activity of the solution.¹

CClF₂C(O)OH and CBrF₂C(O)OH

Equilibrium partial pressure of the acid obtained using a stripping technique over a solution containing 0.15 to 6.0 mol kg⁻¹ HBr to suppress dissociation. Reported values corrected for the effect on the activity of the solution.¹

CBr₃C(O)OH

Equilibrium partial pressure of the acid obtained using a stripping technique over a solution containing 0.15 to 6.0 mol kg⁻¹ HBr to suppress dissociation. Reported values corrected for the effect on the activity of the solution.¹ Only a few measurements at 308 K and one at 298 K were made. The reported value of B is the mean of those for CF₃C(O)OOH and CCl₃C(O)OOH.¹

Note 29: Halogens

[Back to Table](#)

Cl

From the reduction potential E°(Cl/Cl⁻) = (2.43 ± 0.03) V, together with the Gibbs energy for the anion and the gas-phase atom. The potential was derived from an analysis of the reaction of OH with Cl⁻, yielding the equilibrium constant for OH + Cl⁻ + H⁺ ↔ H₂O + Cl (K_{eq} = 1.1 × 10⁵ M⁻², corrected to a standard state of water at unit activity),⁸ and the reduction potential E°(OH⁻, H⁺/H₂O) = (2.73 ± 0.02) V.⁷

Cl₂

Three-parameter refit to the recommendation of Battino.³ Two parameter fit gives A = 9.38 and B = 2090 K for the temperature range 283–313 K. A more recent study in which the chlorine solubility was determined by measuring the total molecular chlorine concentration in contact with pure chlorine gas resulted in values of 0.11 mol L⁻¹ atm⁻¹ at 10°C, 0.074 at 20°C, and 0.052 at 30°C.¹

- Br₂** The results of Kelley and Tartar⁶ and Jenkins and King⁵ agree well below about 313 K, and with the 298 K point of Hill et al.⁴ Recommendation based on a two-parameter fit to all data at and below 308 K.
- BrCl** The recommendation is from the work of Barlett and Margerum.²

Note 30: Inorganic Halogen Species

[Back to Table](#)

- ClO** From the reduction potential $E(\text{ClO}/\text{ClO}^-) = (1.41 \pm 0.02)\text{V}$, which is based on an equilibrium with carbonate at high pH and ionic strength.⁵ This was combined with the Gibbs energy of the anion and the gas-phase radical to obtain the free energy of solution. Due to the high ionic strength, 3 M, it was not possible to correct the potential value and obtain a reduction potential for the standard state. Thus, the derived Henry's law constant must be considered uncertain.
- Cl₂O** Fit to recommendation of Wilhelm et al.⁷ Data appear somewhat uncertain.
- ClO₂** Two-parameter fit to the recommendation of Battino.¹
- HOCl** Huthwelker et al.⁶ analyzed the limited data for pure water from Blatchley et al.,² Holzwarth et al.,⁴ and the more extensive data for uptake by sulfuric acid from Hanson and Ravishankara,³ along with thermodynamic information, and obtained a consistent expression for the solubility of HOCl.
- HOBr** The Henry's law constant was estimated to be more than twice that of HOCl based on a study of the effective Henry's law constant for free bromine from a stripping column.²

Note 31: Inorganic Sulfur Species

[Back to Table](#)

- SO₂** The recommendation of Battino¹ was accepted and refit to a three-parameter equation. The earlier recommendation of Edwards et al.³ is slightly lower. A two parameter fit gives $A = -9.53$ and $B = 2930$ K for the temperature range 278–298 K. New value of $h_{\text{SO}_2,0}$ from absorption equilibria studies in aqueous HCl and NaCl solutions.⁸ Temperature dependence, h_T , from the optimization of Weisberger and Schumpe.¹⁰
- H₂S** In the recommendation of Fogg,⁵ two expressions were given, representing the results above and below 283 K. The predicted values from these expressions were calculated, with the points at 283 K averaged, converted to the desired units, and then fit with the two- and three-parameter expressions. These are the recommended values. More recent results of Rinker and Sandall⁷ and Munder et al.⁶ are slightly lower; in these studies, the physical solubility of H₂S was determined through measurements involving aqueous solutions of glycols or amines, neutralized with HCl. The reported values of De Bruyn et al.² are significantly (~30%) lower. The earlier recommendation of Edwards et al.³ is very close to the recommendation of Fogg⁵ as is the recommendation of Yaws et al.¹² The room temperature point calculated from the NBS Thermodynamic tables Wagman et al.⁹ is also slightly lower. The work of De Bruyn et al.² covered also a wide range of NaCl and (NH₄)₂SO₄ concentration and of pH. Salt effect parameters taken from the optimization of Weisberger and Schumpe.¹⁰
- CS₂** The recommendation is from a fit to data of Elliott,⁴ who also present data in 0.5 mol L⁻¹ NaCl. The results of De Bruyn et al.² are significantly (50%) lower. The work of De Bruyn et al.² covered also a wide range of NaCl and (NH₄)₂SO₄ concentration and of pH. Salt effect parameters derived from the ratio of the solubility of CS₂ in water and 0.5 M NaCl.¹ At 278 K, $k_s = 0.184$ M⁻¹, compared to 0.150 M⁻¹ from the results of De Bruyn, et al. Note also De Bruyn, et al.² obtained $K_s = 0.410$ M⁻¹ for (NH₄)₂SO₄, whereas these parameters would predict 0.261 M⁻¹.
- COS** The reviews by Wilhelm et al.¹¹ and Yaws et al.¹² result in identical values over the low temperature range (<303 K) and are combined to generate the recommendation. The results of De Bruyn et al.² are somewhat (~25%) lower at the lower temperature range. The work of De Bruyn et al.² covered also a wide range of NaCl and (NH₄)₂SO₄ concentration and of pH.

Note 32: Organic Sulfur Species

[Back to Table](#)

CH₃SH The recommendation is based on the data of Przyjazny et al.⁴ Results of De Bruyn et al.³ are about half the recommended value at 298 K. The work of De Bruyn et al.³ covered a wide range of pH and NaCl and (NH₄)₂SO₄ concentrations. At 298 K, they obtained K_s = 0.314 M⁻¹ for (NH₄)₂SO₄ and K_s = 0.143 M⁻¹ for NaCl. From the latter, we calculate h_G = 0.003 M⁻¹; the values for (NH₄)₂SO₄ from this work have tended to be high.

C₂H₅SH The recommendation is based on the data of Przyjazny et al.⁴ The results of Vitenberg⁶ are slightly lower than the extrapolated value at 293 K.

CH₃SCH₃ The recommendation is based on the values of Dacey et al.² The single temperature point of Wong and Wang⁸ and the higher temperature results of Przyjazny et al.⁴ are in good agreement. The results of De Bruyn et al.³ are about 30% lower. A more recent value of 0.47 M atm⁻¹ at 298 K, in good agreement with the value recommended here, was obtained by a dynamic gas stripping approach coupled to a mass spectrometer.⁵ The studies of Dacey et al.² and Wong and Wang⁸ were also carried out with seawater. The work of De Bruyn et al.³ covered also a wide range of NaCl and (NH₄)₂SO₄ concentration and of pH. Salt effect parameters based on the values of Dacey et al.² for Sargasso sea water from 0 to 29 C. The values for K_H obtained by Wong and Wang⁸ for sea water from 18 to 44 C are in good agreement. Dacey et al.² also measured K_H at 18 C for NaCl solutions up to 32%. For the 10–32% data, a value of K_s = 0.117 M⁻¹ can be derived, in good agreement with the predicted value of 0.113 M⁻¹. The 278 K value of K_s = 0.180 M⁻¹ obtained by De Bruyn et al.³ is somewhat larger. Note also the De Bruyn, et al.³ obtained K_s = 0.332 M⁻¹ for (NH₄)₂SO₄, whereas these values would predict 0.223.

CH₃SC₂H₅, C₂H₅SC₂H₅, CH₂CHCH₂SCH₃, higher alkyl sulfides

Obtained by a dynamic gas stripping approach coupled to a mass spectrometer.⁵ An uncertainty of ±0.03 M atm⁻¹ was estimated for CH₃SC₂H₅, of ±0.01 M atm⁻¹ for C₂H₅SC₂H₅, and ±0.02 M atm⁻¹ for CH₂CHCH₂SCH₃.

CH₃S(O)CH₃

The recommendation is from Watts and Brimblecombe⁷ cited by Allen et al.¹

CH₃NCS, methyl isothiocyanate

Measured by stripping technique in pure water.⁹ Measurements in NaCl and buffer solutions tended to be lower (0.1 M NaCl, 9 M atm⁻¹; 0.2 M, 7 M atm⁻¹).

CH₃SSCH₃ and C₂H₅SSC₂H₅

Obtained by a dynamic gas stripping approach coupled to a mass spectrometer.⁵ An uncertainty of ±0.04 M atm⁻¹ was estimated for CH₃SSCH₃ and ±0.03 M atm⁻¹ for C₂H₅SSC₂H₅.

Table 5-5. Ion-Specific Schumpe Parameters

Cation	h_i^c		Anion	h_i^a
H ⁺	0		OH ⁻	0.0839
Li ⁺	0.0754		HS ⁻	0.0851
Na ⁺	0.1143		F ⁻	0.092
K ⁺	0.0922		Cl ⁻	0.0318
Rb ⁺	0.0839		Br ⁻	0.0269
Cs ⁺	0.0759		I ⁻	0.0039
NH ₄ ⁺	0.0556		NO ₂ ⁻	0.0795
Mg ²⁺	0.1694		NO ₃ ⁻	0.0128
Ca ²⁺	0.1762		ClO ₃ ⁻	0.1348
Sr ²⁺	0.1881		BrO ₃ ⁻	0.1116
Ba ²⁺	0.2168		IO ₃ ⁻	0.0913
Mn ²⁺	0.1463		ClO ₄ ⁻	0.0492
Fe ²⁺	0.1523		IO ₄ ⁻	0.1464
Co ²⁺	0.168		CN ⁻	0.0679
Ni ²⁺	0.1654		SCN ⁻	0.0627
Cu ²⁺	0.1675		HCrO ₄ ⁻	0.0401
Zn ²⁺	0.1537		HCO ₃ ⁻	0.0549
Cd ²⁺	0.1869		CO ₃ ²⁻	0.1423
Al ³⁺	0.2174		HPO ₄ ²⁻	0.1499
Cr ³⁺	0.0648		SO ₃ ²⁻	0.127
Fe ³⁺	0.1161		SO ₄ ²⁻	0.1117
La ³⁺	0.2297		S ₂ O ₃ ²⁻	0.1149
Ce ³⁺	0.2406		PO ₄ ³⁻	0.2119
Th ⁴⁺	0.2709		Fe(CN) ₆ ⁴⁻	0.3574

The values in this table can be used to estimate the solubility of a gas in various mixed electrolyte solutions, even if these data have not been obtained experimentally for all of the ions. For example, the solubility of ozone in a solution of 0.8 M HCl and 1.2 M Na₂SO₄ at 273 K would be estimated as follows:

First, $H^0 = 0.024 \text{ M atm}^{-1}$ at 273 K, from the Henry's Law Table; from the same Table, the gas-specific parameters for ozone are $h_{G,o} = 0.00396 \text{ M}^{-1}$ and $h_T = 1.79 \times 10^{-3} \text{ M}^{-1} \text{ K}^{-1}$, thus:

$$k_G = 0.00396 + 1.79 \times 10^{-3} \times (273 - 298) = -0.0408 \text{ M}^{-1}$$

The specific ion parameters from Table 5-4 are corrected by this value to calculate the change in the logarithm of the Henry's law constant

$$\log (H^0/H^{273}) = 2 \times 1.2 \text{ M} \times (0.1143 - 0.0408) \text{ M}^{-1} + 1.2 \text{ M} \times (0.1117 - 0.0408) \text{ M}^{-1} +$$

$$0.8 \text{ M} \times (0 - 0.0408) \text{ M}^{-1} + 0.8 \text{ M} \times (0.0318 - 0.0408) \text{ M}^{-1} = 0.181$$

$$\text{Thus, } (H^0/H^{273}) = 1.517$$

$$H = 0.024 \text{ M atm}^{-1}/1.517 = 0.016 \text{ M atm}^{-1} \text{ for O}_3 \text{ in this salt solution at 273 K.}$$

Table 5-6. Henry's Law Constants for Acids

	T(K)	Wt.% H ₂ SO ₄	H or H* (M/atm)	Notes
O ₃ in H ₂ SO ₄ •nH ₂ O(l)	293	1–70	$\ln(H_o/H) = (4.08 \pm 0.2) \times 10^{-3} \times \text{wt}$ $H_o = 0.012 \text{ M atm}^{-1}$ wt is the H ₂ SO ₄ wt%	1

5.20 Notes to Table 5-6

1. **O₃ in H₂SO₄•nH₂O(l).** Bubble train uptake measurements were performed by Rattigan et al.¹ at 293 K for 1–70 wt% H₂SO₄. Recommended expression is a Sechenov coefficient formulation where $H_o = 0.012 \text{ M atm}^{-1}$ is the 293 K value of H for pure water from Wilhelm et al.² In the measurement, account was taken of the loss of O₃ due to reaction with H⁺.

2. **NO₂ in H₂SO₄•nH₂O(l).** Langenberg et al.¹ present novel capillary gas chromatography measurements for 39, 59, and 68 wt% H₂SO₄ over the temperature range of 203 to 243 K. However, NO₂ solubility must be derived from chromatographic waveforms, which are contorted by much higher N₂O₄ solubility. The resulting values for H_{NO_2} are in the 1 to 10² range, but show inconsistent trends with temperature and concentration, indicating possibly large systematic error.

3. **HONO in H₂SO₄•nH₂O(l).** Becker et al.¹ measured HONO partial pressure, P_{HONO} , over bulk solutions in a temperature range of 248–298 K and a H₂SO₄ concentration range of 0–67 wt%. Longfellow et al.² measured P_{HONO} in a wetted wall flow reactor over a temperature range of 218–295 K and an acid concentration range of 60–83 wt%. Agreement between these two data sets is excellent. H^* decreases from 0 wt% to 53 wt% due to physical solubility, then increases above 53 wt% due to protonation and/or association with H₂SO₄ to make nitrosyl sulfuric acid. Becker et al. parameterized their data as a function of sulfuric acid wt% and temperature. However, the Becker et al. parameterization is not able to fit the combined sets of Becker et al.¹ and Longfellow et al.² data, particularly at the lower temperatures and higher wt% most relevant to the stratosphere. Therefore, the recommended functional form was used to fit the data for >60 wt%. This function fits both sets of data very well. It is important to note that this function is only valid for H₂SO₄ concentrations near 60 wt% and above. The parameterization in Becker et al.¹ should be used to calculate H for H₂SO₄ concentrations <60 wt%. (Note that the units for H are mol/kg-bar in Becker et al.¹ The density parameterization of Myhre et al.³ was used to convert to M/atm units.)

4. **HNO₃ and HCl in H₂SO₄•nH₂O(l) and H₂SO₄•nHNO₃•mH₂O(l).** Effective Henry's law coefficients, H^* , for HNO₃, and HCl in binary H₂SO₄/H₂O and ternary H₂SO₄/HNO₃/H₂O solutions over the temperature range 195 to 300 K are required to model the composition and heterogeneous chemistry of stratospheric and upper tropospheric aerosols. Solubility data can be obtained from analysis of heterogeneous uptake experiments with the liquid phase diffusion coefficient estimated from acid solution viscosity (Williams and Long¹⁵). Solubilities can also be obtained from equilibrium or from vapor pressure data.
 Experimental solubility data for HNO₃ is provided by Van Doren et al.,¹² Reihs et al.,⁹ and Zhang et al.¹⁶ Data for HCl solubility is provided by Watson et al.,¹³ Hanson and Ravishankara,^{5,6} Zhang et al.,¹⁶ Williams and Golden,¹⁴ Abbott,¹ Elrod et al.,⁴ and Robinson et al.¹⁰

These studies all show that trace species solubility in H₂SO₄/H₂O and H₂SO₄/HNO₃/H₂O solutions is a strong function of water activity, which, in turn, depends on both temperature and acid concentrations. Prediction of

HNO₃ and HCl H* values for atmospheric compositions requires a sophisticated model. Comprehensive thermodynamic models of acid solutions for a range of atmospheric conditions have been published by Carslaw et al.,² Tabazadeh et al.,¹¹ and Luo et al.⁷ and reviewed by Carslaw et al.³ These models do an excellent job of reproducing the available experimental data, even for ternary H₂SO₄/HNO₃/H₂O solutions (Elrod et al.⁴). These models and the Carslaw et al.³ review should be consulted for plots/predictions of H* for HNO₃ and HCl in strong acid solutions over the atmospheric temperature range. The most widely used model of Carslaw et al.² was revised in Massucci et al.⁸

5. **HO₂NO₂ in H₂SO₄·nH₂O(l).** Zhang et al.³ performed wetted wall flow reactor studies using CIMS to detect HO₂NO₂ uptake over a temperature range of 201–230 K and an acid concentration range of 52.9–74 wt% H₂SO₄. HD₁^{1/2} values were determined for 52.9, 58.3/59.1, 66.4 and 73.8/74 wt%, with 5 to 15 data points per temperature or temperature pair. All uptake appeared to be reversible with the variation in H strongly temperature dependent, but only moderately dependent on H₂SO₄ wt%. D₁ values were calculated from a cubic cell model to derive H. Uncertainties in measured H values were estimated by authors to be 25% for H < 1 × 10⁶ M atm⁻¹ and 50% for H > 1 × 10⁶ M atm⁻¹. These data were parameterized by Leu and Zhang² in the Sechenov coefficient form adopted by Huthwelker et al.¹ for HOCl, and their formulation is recommended.

6. CH₂O in H₂SO₄•mHNO₃•nH₂O(l). The recommended Henry's Law relationship is:

$$H^* = H(1 + K_2 a_{H_2O} + K_3 a_{H^+})$$

where: $H = 3.4 \times 10^{-5} \exp[-(-0.0456 + 55.5/T)(0.46 m_{H_2SO_4} + 0.13 m_{HNO_3})]$ M atm⁻¹, T is the temperature in K, and $m_{H_2SO_4}$ and m_{HNO_3} are the respective acid molalities; $K_2 = \exp(4020/T - 5.83)$ M⁻¹, $K_3 = 0.56 \exp[8.84 - (T - 260/T)]$ M⁻¹, and a_{H_2O} and a_{H^+} are the water and H⁺ activities which are obtained from a thermodynamic model of the solution, e.g. Carslaw et al.¹ Valid for 10–85 wt% H₂SO₄, 8–40 wt% HNO₃, T = 240–300 K.

Knudsen cell studies by Tolbert et al.⁴ and Iraci and Tolbert² and droplet train/flow reactor studies by Jayne et al.³ all yield data showing that CH₂O is strongly absorbed by sulfuric acid solutions, and Jayne et al. also provide data for ternary acid solutions. The Jayne et al.³ study included H₂SO₄ concentrations from 10 to 85 wt% and HNO₃ concentration between 8 and 40 wt% with temperature variations from 241 to 300 K. These data were parameterized with three terms, representing physical CH₂O solubility, reversible hydrolysis to CH₂(OH)₂, important in more dilute solutions, and reversible formation of CH₃O⁺, dominant at high acidities. The Jayne et al.³ parameterization is recommended above. The H* data from Iraci and Tolbert² cover 49 to 95 wt% H₂SO₄ and a temperature range of 197 to 214.5 K and are in fair agreement with extrapolation of H* expression from Jayne et al.³ for concentrations below ~75 wt%. However, the Iraci and Tolbert data are taken on such thin acid films that initial uptake slopes are difficult to determine accurately and the data scatter is large. While the Iraci and Tolbert data do indicate significantly larger H* values for H₂SO₄ concentrations above 75 wt%, the data do not compel a reformulation of the Jayne et al. parameterization.

7. CH₃OH in H₂SO₄•nH₂O(l). H* data from Kane and Leu,³ taken over 40–85 wt% H₂SO₄ and from 210–235 K, indicate soluble uptake below 65 wt% and predominately reactive uptake to form methanesulfonic acid and dimethylsulfate above 65 wt%. Uptake decreased slightly with temperature below 65 wt% and increases slightly with temperature above. Data yield H*k^{1/2} at high acid concentrations. Weakly temperature dependent γs of ~0.15 were measured for 65, 75, and 80 wt%. However, Knudsen cell studies by Iraci et al.¹ at 45, 61 and 72 wt% over a 197–223 K temperature range show only well behaved reversible uptake. They argue that low vapor pressures explain the lack of CH₃OH recovery for the short observation times used by Kane and Leu. They also cite three older literature studies on the reaction of methanol and ethanol at room temperature in sulfuric acid which report reaction rate constants much lower than those deduced by Kane and Leu.¹ Iraci et al. present the following parameterization of their data plus data for water:

$$\log H^* = A + 1000B/T$$

where $A = 7.00 + \log M_{H_2O}$, $B = 0.000619 m^2 + 0.00544 m + 2.267$, M_{H_2O} is the molarity of water in the solution (mol L⁻¹) and m is the molality of the H₂SO₄ (moles H₂SO₄ per kg H₂O).

Note that this parameterization is based only on the Iraci et al. data. A reanalysis of the Kane and Leu³ results to provide additional data in the 40–72 wt% range, and H* values for higher wt% should be undertaken to validate and extend the Iraci et al. data.

Iraci et al.² used infrared spectroscopy to monitor the production of gas phase methyl nitrate, CH₃ONO₂, from the bulk reaction of ternary sulfuric acid/nitric acid/water solutions with 0.00005–0.005 M CH₃OH in 50.5 to 63.6 wt% H₂SO₄ with 0.03–0.21 M HNO₃ between 278.2 and 328.6 K. This reaction may complicate determinations of Henry's law solubility of methanol in ternary acid solutions when sulfuric acid concentrations are high enough (probably >70 wt%) to produce high levels of NO₂⁺, the assumed nitrating agent.

8. **CH₃CH₂OH in H₂SO₄•nH₂O (l).** Michelsen et al.¹ reported Knudsen cell ethanol uptake experiments for 36–76 wt% H₂SO₄ over a 209–237 K temperature range as well as equilibrium ethanol vapor pressure measurements for 0.5 M ethanol in 59.1 wt% acid between 214.3 and 230.8 K and 0.1 M ethanol in 38.5 wt% acid between 214.0 and 223.9 K. Henry's law solubility parameters from the two methods agreed well. Solubility increased dramatically with increasing acid wt% and decreasing temperature. Michelsen et al. present the following parameterization of their data:

$$\log H^* = A + 1000B/T$$

where $A = \Delta S^\circ/2.303R + \log M_{H_2O}$, $B = 5.319 (\chi_{acid})^2 + 0.812 (\chi_{acid}) + 2.647$, and ΔS° is $-174 \text{ J mol}^{-1} \text{ K}^{-1}$, M_{H_2O} is the molarity of water in the solution calculated at 220K (mol L⁻¹) and χ_{acid} is the mole fraction of sulfuric acid in the solution. Representative values of these parameters are presented in Table 2 of Michelsen et al.¹ Williams et al.³ performed Knudsen cell H* measurements on the effect of 0.1M acetone on the uptake of ethanol by 38.4 wt% H₂SO₄ at 219.1 K yielding $H^* = (2.2 \pm 0.1) \times 10^5 \text{ M atm}^{-1}$ in good agreement with values without added acetone reported by Michelsen et al.¹ and Timonen and Leu;² indicating no effect of added acetone.

Timonen and Leu² calculated H* values from their uptake coefficients on 41.1 wt% H₂SO₄ that are in moderate agreement with the Michelsen et al. parameterization.

9. **CH₃CHO in H₂SO₄•nH₂O(l).** Michelsen et al.¹ reported Knudsen cell acetaldehyde uptake experiments for 39–76 wt% H₂SO₄ over a 211–241 K temperature range. Tabulated H* values for 37 experiments covering four acid concentrations ranged from 2×10^2 to $1.5 \times 10^5 \text{ M atm}^{-1}$; with highest values at highest acid concentration and lowest temperatures. Data for the highest acid concentrations (~76 wt% H₂SO₄) generally indicated simple solubility behavior, while some measurements at lower acid concentrations (39–66 wt%) showed indications of reactive uptake.

Williams et al.² performed Knudsen cell H* measurements on the effect of 0.1M ethanol or acetone on the uptake of acetaldehyde, reproducing a few temperatures and acid concentrations used for the data reported in Michelsen et al.¹ The solubility of acetaldehyde in acid with 0.1 M ethanol or 0.1 M acetone was nearly an order of magnitude higher than the corresponding organic free measurements. Two measurements at 216.1 and 226.8 K with 0.0016 M formaldehyde added to 38.5 wt% H₂SO₄ showed no H* enhancement over organic free measurements but time resolved uptake measurements showed evidence for enhanced reactive uptake.

- 10. $\text{CH}_3\text{C}(\text{O})\text{CH}_3$ in $\text{H}_2\text{SO}_4 \cdot n\text{H}_2\text{O}(\text{l})$.** Duncan et al.^{2,3} used IR spectra of thin sulfuric acid films to establish that acetone is absorbed as the protonated species. Above 70 wt% protonated acetone undergoes a self-condensation/dehydration reaction to form protonated mesityl oxide, which, in turn, reacts with an additional protonated acetone to form trimethyl benzene. Duncan et al.³ measured reversible uptake and derived Henry's law constants for 70 wt% H_2SO_4 at 180, 187 and 195 K and a value at 201 K for 76 wt%. Kane et al.⁶ measured uptake in a wetted wall flow reactor and derived H^* parameters for 40, 50, 65, and 75 wt% over a much wider temperature range than Duncan et al.³ Their data diverge above 80 wt% which they attribute to reactive uptake as suggested by Duncan et al.^{2,3} Klassen et al.⁷ provide Knudsen cell uptake derived data for 48.7 to 78.3 H_2SO_4 wt% between 210 and 240 K that are generally consistent with that of Kane et al.⁶ Imamura and Akiyoshi⁵ report wetted wall flow reactor H^* measurements at 230 K for 50 and 60 wt%, 250 K for 60, 69 and 76 wt%, and 270 K for 76 and 79 wt%; their data diverges a factor of 2 to 4 from that of Kane et al.⁶ and Klassen et al.⁷

Equally weighted data sets from Kane et al.⁶ and Klassen et al.⁷ were combined and fit to generate the recommended parameterization. Two points for the solubility of acetone in water at 298 K and 273 K (Benkelberg et al.¹) were included to improve the extrapolation to low wt% solutions. The data points from Imamura and Akiyoshi⁵ were not included because they were inconsistent with the other data and have a very different temperature dependence. The few data points from Duncan et al.^{2,3} are also inconsistent with the other data and were not included in the parameterization. Using a rotating wetted-wall flow reactor Esteve and Nozière⁴ measured H^* coefficients at $298 \pm 3\text{ K}$ for 89.4, 85, 80.8 73.9 and 70 wt% H_2SO_4 , reporting values of 840, 650, 500, and 320 M atm^{-1} , respectively. These data are not included in the recommended parameterization since the temperature/wt% ranges they cover are unlikely to occur in the atmosphere.

Williams et al.⁸ performed Knudsen cell H^* measurements on the effect of 0.1 M ethanol on the uptake of acetone by 38.4 to 75.0 wt% H_2SO_4 at temperatures between 217.6 and 238.5 K, corresponding to data points previously reported by Kane et al. and Klassen et al. Their data indicated that the added ethanol had "no significant effect" on the solubility of acetone for comparable ethanol free measurements.

11. **CH₃C(O)O₂NO₂ in H₂O and H₂SO₄•nH₂O(l).** Zhang and Leu⁵ performed wetted wall flow reactor studies using CIMS to detect CH₃C(O)O₂NO₂ uptake over a temperature range of 199 to 226 K. Uptake studies were performed at 46, 54, 59, and 72 wt% H₂SO₄ to yield H^{*}D₁^{1/2} values. D₁ values were calculated from a cubic cell model to derive H^{*}. Leu and Zhang⁴ fit their data from Zhang and Leu,⁵ including water data from Kames and Schurath² and Kames et al.,³ using the Sechenov coefficient form adopted by Huthwelker for HOCl.¹ This formulation is recommended for both water and sulfuric acid solutions.

15. **ClONO₂ in H₂SO₄•nH₂O(l).** Recommendation is from the model of Shi et al.² who used a measurement of the hydrolysis reaction's reacto-diffusive length by Hanson and Lovejoy¹ on 60 wt% H₂SO₄ at 250 K to derive the hydrolysis rate constant, k_{hyd}, and constrain H_{ClONO2} at 250 K. Shi et al. fit the Hk^{1/2} dependence of the ClONO₂ uptake coefficients for a variety of ClONO₂ hydrolysis and ClONO₂ + HCl data to derive a parameterization for H as a function of wt% and T.

- 16. HBr in H₂SO₄•mHNO₃•nH₂O(l).** Experimental data for HBr solubility is provided by Williams et al.,⁷ Abbatt,¹ Abbatt and Nowak,² Kleffman et al.,⁴ and Behr et al.³ Data from time-dependent uptake measurements and from vapor pressure measurements are in good agreement after correcting for the fact that for some of the vapor pressure measurements the HBr concentration in solution was high enough to increase the acidity and thereby decrease the HBr solubility. By comparing pairs of data points with different HBr concentrations (from the same experiment), an average correction factor was obtained. The correction factor was used to correct the vapor pressure data of Williams et al.,⁷ Abbatt and Nowak,² and Kleffmann et al. to zero effective HBr concentration. (This is different than the approach taken in Kleffmann et al. of using a “corrected” H₂SO₄ wt%. However, the resulting parameterization is very similar to the one in Kleffmann et al.⁴) The time-dependent uptake data of Williams et al.⁷ and Abbatt,¹ and the molecular beam uptake data of Behr et al.³ did not require correction. All of the experimental data have been fit to obtain the recommended parameterization as a function of H₂SO₄ wt% and temperature.

Agreement between this parameterization and the updated activity coefficient model of Massucci et al.⁶ (and <http://www.hpc1.uea.ac.uk/~e770/aim.html>) is good for >60 wt%, but not very good at lower H₂SO₄ wt%, particularly at low temperatures. Therefore, this parameterization is recommended for calculating HBr Henry's law solubilities.

The only data for HBr solubilities in ternary solutions is from Kleffmann et al.⁴ The data do not agree well with the updated activity coefficient in Massucci et al.⁴ or with the older activity coefficient model in Luo et al.⁵ Until further information becomes available, the recommendation is to use the parameterization for ternary solutions given in Kleffmann et al.⁴

- 17. HOBr in H₂SO₄•nH₂O(l).** HOBr solubility measurements have been reported from coated wall flow reactor uptake studies by Waschewsky and Abbatt³ and Hanson¹ and from Knudsen cell uptake studies from Iraci et al.² Although they were performed in different temperature ranges, extrapolations of Hanson's higher temperature data to the temperature range investigated by Waschewsky and Abbatt predicted much higher HOBr solubility than they measured. Iraci et al. subsequently measured HOBr uptake over both of the temperature ranges covered in the prior experiments. Their data agreed well with data from Waschewsky and Abbatt³ at lower temperatures (213–238 K) but fall far below Hanson's higher (250–270 K) temperature measurements. The Iraci et al. measurements were performed at ~45, 55, 61 and 70 wt% H₂SO₄ and investigated over the temperature range from 201 to 252 K. Their results, like the earlier studies, indicate that

the dependence of H^* on acid concentration is relatively weak. For H_2SO_4 acid wt% from 55 to 75, H^* is well described by: $\log H^* = (2349 \pm 280)/T - (5.27 \pm 1.24)$. Their ~45 wt% data are fit by: $\log H^* = (3665 \pm 270)/T - (10.63 \pm 1.23)$.

- 18. SO_2 in $H_2SO_4 \cdot nH_2O(l)$.** Room temperature vapor pressure measurements reviewed by Hayduk et al.¹ and bubble train reactor uptake measurements by Rattigan et al.⁴ for 0–70 wt% H_2SO_4 agree very well. Langenberg et al.² used a novel capillary gas chromatography technique to deduce H^* values for 41–83 wt% H_2SO_4 over a temperature range of 193–242 K. The recommended parameterization is a fair fit to the Rattigan et al. and Langenberg et al. data sets and allows reasonable extrapolation over the full range of atmospheric temperatures. Note that the Langenberg et al.² data is in mol/kg-bar units and was converted to mole/l units using the density parameterization of Myhre et al.³

Substance	Temperature Range, K	$H(298\text{ K})$ (M atm ⁻¹)	A	B (K)	Uncertainty Range	Note
C ₂ Cl ₄	275–318	0.047	–17.635	4350	II	11
C ₂ H ₅ I	274–303	0.14	–18.06	4800	IV	12

Uncertainty Classes:

I—Better than 10%

II—10% to 50%

III—50% to 100%

IV—Factor of 2 to factor of 10

V—Factor of 10 to factor of 100

VI—Greater than a factor of 100

5.22 Notes to Table 5-7

Note 1: Inorganic Gases

[Back to Table](#)

- N₂O.** Measurements at 36.13‰ NaCl using a microgasometric technique.⁵ Data taken from the IUPAC evaluation.⁷
- CO.** The two published reports on the solubility of CO into salt water were evaluated by Wiesenburg,⁶ who concluded that the data of Douglas¹ were significantly more reliable than those of Schmidt.³ Those data were fit to a function of temperature and salinity. The present recommendation takes this function, calculates the values for 35‰ salinity, and fits those results to a two-parameter equation. A three parameter fit over the temperature range 274–303 K yields $\ln H = -179.224 + 8620/T + 25.13\ln(T)$.
- CO₂.** Published data on the solubility of CO₂ into salt water were evaluated by Weiss,⁴ who also carried out some confirmatory measurements. The extensive results of Murray and Riley² were accepted and fit as a function of temperature and salinity. The present recommendation for seawater takes the calculated values for 35‰ salinity and the newer values for 35.33‰ and fits them to a two-parameter equation over the indicated temperature range. A three parameter fit over the temperature range 272–313 K yields $\ln H = -157.779 + 8810/T + 21.88\ln(T)$.

Note 4: Fluorochloromethanes

[Back to Table](#)

- CHF₂Cl.** Gas solubilities measured at 278, 308, and 338 K and at NaCl concentrations from 0 to 0.0564 mole/mole (0 to 174‰) with a gas absorption unit.⁴ Calculated values for 35‰ NaCl taken at each temperature and fitted to a two-parameter equation. These values were double-weighted and fit together with the values measured² in seawater by a purge-and-trap technique.
- CFCl₃.** A linear fit to the results of Hunter-Smith, et al.¹ and Ooki and Yokouchi² in seawater. The results are in good agreement at low temperatures (<293 K) but diverge at room temperature and above.
- CF₂Cl₂, CF₃Cl.** Ostwald coefficients determined in filtered seawater with a salinity of 35‰.³ Results fit to a linear equation.
- (1) Hunter-Smith, R. J.; Balls, P. W.; Liss, P. S. Henry's law constants and the air-sea exchange of various low molecular weight halocarbon gases. *Tellus* **1983**, *35B*, 170-176.

- (3) Scharlin, P.; Battino, R. Solubility of CCl_2F_2 , CClF_3 , CF_4 , and CH_4 in water and seawater at 288.15-303.15 K and 101.325 kPa. *J. Chem. Eng. Data* **1995**, *40*, 167-169.
- (4) Zheng, D.-Q.; Guo, T.-M.; Knapp, H. Experimental and modeling studies on the solubility of CO_2 , CHClF_2 , CHF_3 , $\text{C}_2\text{H}_2\text{F}_4$ and $\text{C}_2\text{H}_4\text{F}_2$ in water and aqueous NaCl solutions under low pressures *Fluid Phase Equilibria* **1997**, *129*, 197-209.

Note 5: Chloromethanes

[Back to Table](#)

- CH₃Cl.** From a measurement of the concentration of the substance in a column of seawater at 30.4 or 34.34‰ salinity as a stream of nitrogen is bubbled through.^{5,6} Similar results were reported by Elliott and Rowland at 0 and 22°C.³
- CH₂Cl₂.** From a measurement of the concentration of the substance in a column of seawater at 34.34‰ salinity as a stream of nitrogen is bubbled through⁵ combined with values determined in seawater of salinities of 33.1‰ to 36.1‰ by using a purge-and-trap method and an equilibrator.⁷
- CHCl₃.** Taken from a linear fit to the results of Moore, et al.,^{5,6} Hunter-Smith et al.,⁴ and Dewulf, et al.² The latter were from a study as a function of salinity and the calculated value at 35‰ was used. These data were double-weighted in the fit. A measurement at 25°C with a purge-and-trap/GC method gave a result in close agreement.⁸

- CCl₄.** A linear fit to the results of Hunter-Smith, et al.,⁴ Bullister and Wisegarver,¹ and Dewulf, et al.² The latter were from a study as a function of salinity and the calculated value at 35‰ was used. These data were double-weighted in the fit. The Bullister and Wisegarver¹ data were from a study of the solubility as a function of temperature and salinity. Calculated values for 35‰ from a complex expression were used.

Note 6: Bromomethanes

[Back to Table](#)

- CH₃Br.** Solubility determined with a gas-liquid membrane equilibrator with a 35‰ NaCl solution.¹ An approximately 5% correction was applied for non-ideality and to express the result in terms of fugacities. Very similar values were measured for filtered seawater. The results of Elliott and Rowland at 0 and 22°C are very close to these.²
- CH₂Br₂.** From a measurement of the concentration of the substance in a column of seawater at 34.34‰ salinity as a stream of nitrogen is bubbled through³ combined with values determined in seawater of salinities of 33.1‰ to 36.1‰ by using a purge-and-trap method and an equilibrator.⁵
- CHBr₃.** A linear fit to the results from a purge-and-trap method,⁵ calculated from the expression presented, and with a stripping technique with mass spectrometric detection.⁴ Another measurement at 25°C with a purge-and-trap/GC method gave a result about 50% higher.⁶

Note 7: Chlorobromomethanes[Back to Table](#)**CHBrCl₂.**

A linear fit to the results measured by a stripping technique at a salinity of 30.4‰.¹ A measurement at 25°C with a purge-and-trap/GC method gave a bit higher result.²

CHBr₂Cl.

A linear fit to the results from a stripping technique at a salinity of 30.4‰.¹ A measurement at 25°C with a purge-and-trap/GC method gave a result about 20% higher.²

- (1) Moore, R. M.; Geen, C. E.; Tait, V. K. Determination of Henry law constants for a suite of naturally-occurring halogenated methanes in seawater. *Chemosphere* **1995**, 30, 1183-1191.

Note 11: Chloroethanes

[Back to Table](#)

1,1-C₂H₄Cl₂.

Derived from an equilibrium partitioning study as a function of salinity and temperature.¹ The derived value at 35‰ at each temperature was used.

1,2-C₂H₄Cl₂.

Derived from an equilibrium partitioning study as a function of salinity and temperature.¹ The derived value at 35‰ at each temperature was used. The data at 2°C were rejected due to a high reported standard deviation and a poor fit to the other results.

1,1,1-C₂H₃Cl₃.

The results from a multiple equilibration technique,² were combined with the derived values at 35‰ at each temperature from an equilibrium partitioning study as a function of salinity and temperature.¹ The highest temperature point from this latter study was not included in the fit.

C₂HCl₃, C₂Cl₄.

A fit to results from measurements of the concentration of the substance in a column of seawater at 34.34‰ salinity as a stream of nitrogen is bubbled through,³ from an equilibrium partitioning study as a function of salinity and temperature,¹ and from a gc/headspace method with seawater of 35‰ salinity.⁴ The derived value at 35‰ at each temperature from Dewulf et al.¹ was used and double-weighted.

Table 6-2. Gas-Phase Entropy and Enthalpy Values at 100 kPa	6-3

6.1 Introduction

Table 6-2 lists selected entropy and enthalpy of formation values at 298 K for a number of atmospheric species. As much as possible, the values were taken from primary evaluations that develop a recommended value from the original studies. Otherwise, the values were selected from the original literature, which is referenced in the table. Often, the enthalpy of formation and the entropy values are taken from different sources, usually due to a more recent value for the enthalpy of formation. The cited error limits are from the original references and therefore reflect often widely varying criteria. Some enthalpy values have been adjusted to reflect the value of a reference compound selected for this table; these are mentioned in the Notes. Values that are calculated or estimated are also indicated in the Notes, along with information on the level of theory. Results other than those recommended are also often mentioned in the Notes, including recommendations from previous versions of this Table. These should provide a better perspective on the selected value. All values in the Table are in SI (Joule) units. In the notes, some values are reported in calorie units (1 cal = 4.184 J).

In order to make the utilization of Table 6-2 more convenient, the species are grouped according to some defining characteristic. Each of these groupings has a number linked to that group in the Table. Each group, in turn, has a linked Note associated with it, in which the group's species are listed sequentially, followed by comments. At the end of each Note, the applicable references are given. Below is a list of these various groups and their group numbers. Formulas are presented in the order: C H O N F Cl Br I S Hg.

Table 6-1. Glossary of Groupings

6.2 Notes to Table 6-2

Note 1: Simple compounds of H and O

[Back to Table](#)

H	Enthalpy value is from the optimization of Ruscic et al. ¹⁷ and is almost the same as the CODATA Key Value, ² but with a smaller error limit. Entropy value from CODATA. ²
H₂	CODATA Key Value. ²
O(³P)	Enthalpy value is from the optimization of Ruscic et al. ¹⁷ CODATA Key Value ² of $\Delta_f H_{298}^\circ = 249.18 \pm 0.10$ kJ mol ⁻¹ was used in previous evaluation. Entropy value is from CODATA.
O(¹D)	Based on a transition to the weighted midpoint of the O ³ P J-levels. ¹³
O₂	CODATA Key Value. ²
O₂(¹Δ_g)	Spectroscopic value from Huber and Herzberg. ¹⁰
O₂(¹Σ_g^+)	Enthalpy value is from the optimization of Ruscic, et al. ¹⁹ Entropy from Gurvich et al. review, which also gave the previously-listed enthalpy of 141.8 ± 2 kJ mol ⁻¹ . ⁸
OH	Enthalpy value is an update ¹⁷ to the recommendation of the IUPAC Task Group. ¹⁸ It is an optimization, based on photoionization measurements. Values based on Birge-Sponer extrapolations of OH vibrational levels are 2.1 kJ mol ⁻¹ higher. The entropy is taken from Gurvich et al. ⁸ A network optimization of <i>ab initio</i> reaction enthalpies results in a value of $\Delta_f H_0^\circ = 36.90 \pm 0.16$ kJ mol ⁻¹ . ³ Uncertainty corresponds to the 95% confidence limit. The reference atomic values were taken from the Active Thermochemical Tables ver. 1.20.
H₂O	The enthalpy and entropy values are the result of an optimization in the Active Thermochemical Tables (ATcT). ¹⁶ Previous values of -241.826 ± 0.040 kJ mol ⁻¹ and 188.835 ± 0.010 J mol ⁻¹ K ⁻¹ are CODATA Key Values. ² A network optimization of <i>ab initio</i> reaction enthalpies results in a value of $\Delta_f H_0^\circ = -239.18 \pm 0.23$ kJ mol ⁻¹ . ³ The uncertainty corresponds to the 95% confidence limit. The reference atomic values were taken from the Active Thermochemical Tables, ver. 1.20.
HO₂	The enthalpy values are from an optimization of a local thermochemical network consisting of 14 experimental and 7 theoretical reaction enthalpies, and grounded in very well established reference enthalpies. ⁶ Most theoretical values from the literature were rejected in favor of determinations at a higher level of theory. In this study, computed values of $\Delta_f H_{298}^\circ = 11.88 \pm 0.33$ kJ mol ⁻¹ and $\Delta_f H_0^\circ = 14.81 \pm 0.33$ kJ mol ⁻¹ were obtained from a composite quantum chemical method discussed in the study, roughly 0.5 kJ mol ⁻¹ lower than earlier values. The previous Table values, $\Delta_f H_{298}^\circ = 11.92 \pm 0.22$ kJ mol ⁻¹ and $\Delta_f H_0^\circ = 14.85 \pm 0.22$ kJ mol ⁻¹ , were from an optimization based on both experimental and theoretical data. ¹⁸ Previous enthalpy value at 298 K of 13.4 ± 2.1 kJ mol ⁻¹ was based upon a negative ion thermodynamic cycle, ¹⁵ which was in good agreement with the photoionization result of 13.8 ± 3.3 kJ mol ⁻¹ . ¹² An earlier network optimization of <i>ab initio</i> reaction enthalpies resulted in a value of $\Delta_f H_0^\circ = 15.09 \pm 0.23$ kJ mol ⁻¹ . ³ The uncertainty corresponds to the 95% confidence limit.
H₂O₂	Enthalpy value based on the enthalpy of formation of liquid H ₂ O ₂ and the enthalpy of vaporization. ²⁰ A CCSD(T) calculation of the atomization energy, employing the cc-pVnZ basis sets (n=T,Q,5,6) led to $\Delta_f H_{298}^\circ = -32.28$ kcal mol ⁻¹ and $\Delta_f H_0^\circ = -30.83$ kcal mol ⁻¹ . ⁵
HO₃	Enthalpy for the reaction $\text{HOOOH} + \text{FOO} \rightarrow \text{HOOF} + \text{HOOO}$ at the CCSD(T)/CBS(Q5) level of theory is 9.50 kcal mol ⁻¹ . Adjusted for the Table reference values, this gives the cited enthalpy of formation. The minimum was found to be the <i>trans</i> configuration at the CCSD(T)/CBS(Q5) level of theory, with the <i>cis</i> configuration 0.5 kcal mol ⁻¹ higher in energy. ⁷ Note that the enthalpy values obtained from the atomization energy were higher, due, apparently, to higher order correlation effects. ⁷ A more recent calculation employing the 2-electron reduced density matrix method suggests that the <i>cis</i> isomer is 1.84 kcal mol ⁻¹ higher in energy than the <i>trans</i> isomer with a aug-cc-pVQZ basis set. ⁹ The selected value is supported by another analysis using theisodesmic reaction $\text{HO}_2 + \text{FOO} \rightarrow \text{HO}_3 + \text{FO}$ which leads to a value of $\Delta_f H_{298}^\circ = 6.3$ kcal mol ⁻¹ . ⁵ An older theoretical study, using both atomization energies and the reaction $\text{HOOO} + \text{HOH} \rightarrow \text{HOOOH} + \text{OH}$, resulted in $\Delta_f H_{298}^\circ = 7.1 \pm 2$ kcal mol ⁻¹ (not adjusted). ⁴ The enthalpy of formation derived from an estimate of the ionization

energy of HO₃, which comes from a study of the electron transfer reactions between HO₃⁺ and a series of neutral substrates, was $\Delta_f H_{298}^0 = -1 \pm 5 \text{ kcal mol}^{-1}$.²⁰ The stability of HO₃ has been supported by a neutralization-reionization mass spectrometry experiment, which led to a lifetime of $>1 \text{ } \mu\text{s}$,¹ and an infrared action spectrum, which leads to an upper limit for the HO-O₂ bond strength of $6.12 \text{ kcal mol}^{-1}$.¹⁴

HO₃H CCSD(T) calculation of the atomization energy, employing the cc-pVnZ basis sets (n=T,Q,5,6).⁵ Reaction enthalpy for the reaction $2 \text{ HOOH} \rightarrow \text{HOOOH} + \text{HOH}$ was calculated to be $-15.5 \text{ kcal mol}^{-1}$ using the G2 method, leading to $\Delta_f H_{298}^0 = -22.7 \text{ kcal mol}^{-1}$.¹¹ Atomization energy calculated by the CCSD(T) extrapolated to the CBS limit, with geometry optimized at the CCSD(T)/aV(n+d)Z (n = D,T,Q,5) level gives $\Delta_f H_{298}^0 = -21.3 \text{ kcal mol}^{-1}$ and $\Delta_f H_0^0 = -19.2 \pm 1 \text{ kcal mol}^{-1}$.⁷

HO₄H CCSD(T) calculation of the atomization energy, employing the cc-pVnZ basis sets (n = T,Q,5,6).⁵

Note 2: Water complexes

[Back to Table](#)

- O₃•H₂O** Structures were optimized using the QCISD approach, using the 6-311G(2df,2p) and G+ with aug-cc-pVDZ and aug-cc-pVTZ basis sets. Single point calculations were carried out using the CCSD(T) method with the same basis sets. The lowest energy complexes have van der Waals structures, not hydrogen-bonding, with the two terminal oxygens of ozone interacting with the oxygen atom of water. The calculated bond dissociation enthalpy is 1.58 kcal mol⁻¹. The structure involving the central oxygen atom of ozone has a slightly weaker bond, but, due to ZPE corrections, a slightly lower enthalpy.²
- OH•H₂O** The structure was optimized with A' symmetry at the CCSD(T)/aug-cc-pVTZ level and a binding energy of 5.88 kcal mol⁻¹ calculated, resulting in the listed formation enthalpy.³ In another calculation, the binding energy for the hydrogen-bonded complex was calculated by optimizing the structure using the PM3 method followed by HF/6-31G* self-consistent field optimization. A G3 calculation leads to a reaction enthalpy of -4.49 kcal mol⁻¹ for the formation of the complex.¹
- H₂O•H₂O** The enthalpy and entropy values are the result of an optimization in the Active Thermochemical Tables (ATcT).⁶
- HO₂•H₂O** Derived from the recommended equilibrium constant for the formation of the complex (Table 3-1, Note 4).
- OCl•OH₂** Obtained from a dissociation energy of 2.70 kcal mol⁻¹, calculated at the MP2//aug-cc-pVTZ level of theory with a quadruple- ζ basic set. Values of 1.70–1.79 kcal mol⁻¹ were calculated using B3LYP with triple to quintuple- ζ bases sets. B3LYP//aug-cc-pVTZ was also used to calculate BDEs for hydrates with up to six water molecules.⁴
- ClO•HOH** Obtained from a dissociation energy of 1.55 kcal mol⁻¹, calculated at the MP2//aug-cc-pVTZ level of theory with a quadruple- ζ basic set. Value of 1.06–1.23 kcal mol⁻¹ were calculated using B3LYP with triple to quintuple- ζ bases sets. B3LYP//aug-cc-pVTZ was also used to calculate BDEs for hydrates with up to six water molecules.⁴
- OBr•OH₂** Obtained from a dissociation energy of 3.48 kcal mol⁻¹, calculated at the MP2//aug-cc-pVTZ level of theory. A value of 2.54 kcal mol⁻¹ was calculated using B3LYP, which was also used to calculate BDEs for hydrates with up to four water molecules.⁵
- BrO•HOH** Obtained from dissociation energy of 1.70 kcal mol⁻¹, calculated at the MP2//aug-cc-pVTZ level of theory. A value of 1.58 kcal mol⁻¹ was calculated using B3LYP, which was also used to calculate BDEs for hydrates with up to four water molecules.⁵

Note 3: Simple compounds of N and H[Back to Table](#)

N(⁴S)	The enthalpy value is the result of an optimization in the Active Thermochemical Tables (ATcT). ⁹ Previous value of 472.420±0.050 kJ mol ⁻¹ derived from a PFI-PEPICO TOF study. ¹⁰ Entropy from CODATA Key Values. ³
N₂	CODATA Key Values. ³
NH	Enthalpy from review of Anderson. ¹ Entropy and enthalpy difference (0.05 kJ mol ⁻¹) from JANAF. ² A network optimization of <i>ab initio</i> reaction enthalpies results in a value of $\Delta_f H_0^\circ = 359.17 \pm 0.17$ kJ mol ⁻¹ . ⁴ The uncertainty corresponds to the 95% confidence limit. The reference atomic values were taken from the Active Thermochemical Tables, ver. 1.20. ⁹
NH₂	Recommended values from the IUPAC Task Group. ⁸ Enthalpy is a weighted average of four measurements since 1982. Previous recommendation was 186±1 kJ mol ⁻¹ . ¹ Entropy was taken from a computed anharmonic potential surface, ⁶ and is close to the JANAF value of 194.71±0.05 kJ mol ⁻¹ . ²
NH₃	CODATA Key Value. ³ The JANAF Tables give $\Delta_f H_0^\circ = -38.91$ kJ mol ⁻¹ , $\Delta_f H_{298}^\circ = -45.90$ kJ mol ⁻¹ , and $S^\circ = 192.774$ J K ⁻¹ mol ⁻¹ . ² A network optimization of <i>ab initio</i> reaction enthalpies results in a value of $\Delta_f H_0^\circ = -38.52 \pm 0.26$ kJ mol ⁻¹ . ⁴ The uncertainty corresponds to the 95% confidence limit. The reference atomic values were taken from the Active Thermochemical Tables, ver. 1.20.
N₂H	Geometry optimized at the frozen core CCSD(T) level of theory with aug-cc-pVDZ and aug-cc-pVTZ basis sets; the CCSD(T) energy extrapolated to the CBS limit. ⁷
<i>trans</i>-N₂H₂	Geometry optimized at the frozen core CCSD(T) level of theory with aug-cc-pVDZ and aug-cc-pVTZ basis sets; the CCSD(T) energy extrapolated to the CBS limit. ⁷ Previous value, 212±10 kJ mol ⁻¹ , taken from the Gurvich et al. review. ⁵ (The same value was used for the equilibrium mixture.)
<i>cis</i>-N₂H₂	Geometry optimized at the frozen core CCSD(T) level of theory with aug-cc-pVDZ and aug-cc-pVTZ basis sets; the CCSD(T) energy extrapolated to the CBS limit. ⁷ Previous enthalpy value, 248±12 kJ mol ⁻¹ , based on enthalpy of conversion of the <i>trans</i> to <i>cis</i> isomers, 36±12 kJ mol ⁻¹ . ⁵
N₂H₃	Geometry optimized at the frozen core CCSD(T) level of theory with aug-cc-pVDZ and aug-cc-pVTZ basis sets; the CCSD(T) energy extrapolated to the CBS limit. ⁷
N₂H₄	Taken from review of Gurvich et al. ⁵ An enthalpy value of 23.1 kcal mol ⁻¹ was obtained using a geometry optimized at the frozen core CCSD(T) level of theory with aug-cc-pVDZ and aug-cc-pVTZ basis sets; the CCSD(T) energy extrapolated to the CBS limit. ⁷

|-----------------------------------|---|
| NO | Enthalpy value is an update ⁷ to the recommendation of the IUPAC Task Group, which is from an optimization based on experimental data. ⁸ Previous enthalpy value, $91.29 \pm 0.17 \text{ kJ mol}^{-1}$ from review of Anderson. ³ Much of the difference can be ascribed to the change in the enthalpy for N. Entropy from JANAF. ⁴ |
| N₂O | Taken from review of Gurvich et al. ⁶ The JANAF Tables give $\Delta_f H_0^\circ = 85.48 \text{ kJ mol}^{-1}$, $\Delta_f H_{298}^\circ = 82.05 \text{ kJ mol}^{-1}$, and $S^\circ = 219.957 \text{ J K}^{-1}\text{mol}^{-1}$. ⁴ |
| NO₂ | The enthalpy value is from an optimization based on experimental data. ⁸ Entropy from Gurvich et al. ⁶ |
| NO₃ | Enthalpy derived from a molecular beam photofragmentation translational spectroscopic study, adjusted to Table values for O and NO ₂ . ⁵ Entropy from review of Abramowitz, et al. ¹ |
| N₂O₃ | Taken from review of Gurvich et al. ⁶ The JANAF Tables give $\Delta_f H_0^\circ = 89.6 \text{ kJ mol}^{-1}$, $\Delta_f H_{298}^\circ = 82.8 \text{ kJ mol}^{-1}$, and $S^\circ = 308.539 \text{ J K}^{-1}\text{mol}^{-1}$. ⁴ |
| N₂O₄ | Taken from review of Gurvich et al. ⁶ The JANAF Tables give $\Delta_f H_0^\circ = 18.7 \text{ kJ mol}^{-1}$, $\Delta_f H_{298}^\circ = 9.1 \text{ kJ mol}^{-1}$, and $S^\circ = 304.376 \text{ J K}^{-1}\text{mol}^{-1}$. ⁴ |
| N₂O₅ | Selected enthalpy value derived from a third-law calculation on the equilibrium constant for the reaction, $\text{NO}_2 + \text{NO}_3 \leftrightarrow \text{N}_2\text{O}_5$, presented in Table 3-1, note 11. Entropy value was calculated by Alecu and Marshall, ² as discussed in Table 3-1. Previous values ($\Delta_f H_{298}^\circ = 13.3 \text{ kJ mol}^{-1}$, and $S^\circ = 355.7 \text{ J mol}^{-1}$) and enthalpy difference taken from review of Gurvich et al. ⁶ The JANAF Tables give $\Delta_f H_0^\circ = 12.7 \text{ kJ mol}^{-1}$, $\Delta_f H_{298}^\circ = 11.3 \text{ kJ mol}^{-1}$, and $S^\circ = 346.548 \text{ J K}^{-1}\text{mol}^{-1}$. ⁴ |

Note 5: Compounds containing N, H, and O

[Back to Table](#)

HNO	Geometry optimized at the frozen core CCSD(T) level of theory with aug-cc-pVDZ and aug-cc-pVTZ basis sets; the CCSD(T) energy extrapolated to the CBS limit. ⁴ Previous enthalpy, 107.1±2.5 kJ mol ⁻¹ , from review of Anderson. ¹ Entropy from Gurvich et al., who cites an enthalpy of 102 kJ mol ⁻¹ . ⁷
HON	Geometry optimized at the frozen core CCSD(T) level of theory with aug-cc-pVDZ and aug-cc-pVTZ basis sets; the CCSD(T) energy extrapolated to the CBS limit. ⁴
NH₂O	Geometry optimized at the frozen core CCSD(T) level of theory with aug-cc-pVDZ and aug-cc-pVTZ basis sets; the CCSD(T) energy extrapolated to the CBS limit. ⁴
NH₂OH	Calculated using isodesmic reactions at several levels of theory and several basis sets. ¹² Previous value of -9.6±2.2 kcal mol ⁻¹ based on average of theoretical and experimental values. ¹ Entropy from Gurvich et al. ⁷
HNOH	Geometry optimized at the frozen core CCSD(T) level of theory with aug-cc-pVDZ and aug-cc-pVTZ basis sets; the CCSD(T) energy extrapolated to the CBS limit. ⁴
NH₂NO₂	The equilibrium geometry was calculated at the CCSD(T)/cc-pVQZ level of theory, while the energy was calculated by summing various contributions calculated at the CCSC(T) level with the use of various basis sets. ¹³ The previous value, Δ _f H ₂₉₈ ⁰ = -26±10 kJ mol ⁻¹ , was based on measurements of the enthalpy of formation of the crystalline substance and an estimated value of the enthalpy of sublimation, 60.7±10 kJ mol ⁻¹ . ⁷
HONO	Thermodynamic properties for the equilibrium mixtures of isomers from Gurvich et al. review. ⁷
trans-HONO	Taken from review of Gurvich et al. ⁷ Values calculated using G3, CBS-QB3, and CBS-APNO methods applied to atomization, isomerization, and work reactions are Δ _f H ₂₉₈ ⁰ = -18.90±0.05 kcal mol ⁻¹ and S ⁰ = 57.89 cal K ⁻¹ mol ⁻¹ . ²
cis-HONO	Enthalpy value obtained on basis of enthalpy of conversion of trans-HONO into cis-HONO, 1.7±0.4 kJ mol ⁻¹ . ⁷ Values calculated using G3, CBS-QB3, and CBS-APNO methods applied to atomization, isomerization, and work reactions are Δ _f H ₂₉₈ ⁰ = -18.40±0.05 kcal mol ⁻¹ and S ⁰ = 57.64 cal K ⁻¹ mol ⁻¹ . ²
trans-HOON, hydroperoxynitrene or nitrosyl O-oxide	The O-O dissociation energy was calculated at the CCSDTQ/aug-cc-pVTZ level of theory as 39.0 kJ mol ⁻¹ . This was corrected to 298 K by -5.7 kJ mol ⁻¹ to give the selected enthalpy value. The cis isomer was calculated to be 6.4–8.5 kJ mol ⁻¹ less stable. ¹⁴
HNO₂, nitryl hydride	Calculated using G3, CBS-QB3, and CBS-APNO methods applied to atomization, isomerization, and work reactions. ²
HONO₂	Taken from the updated NIST-JANAF Tables. ⁵
cis,cis-HOONO	Derived from a third-law analysis of the equilibrium constant for HO + NO ₂ ↔ c,c-HOONO (Table 3-1, Note 1). Previous enthalpy value of -5.7 kcal mol ⁻¹ and values for the cis,perp- and trans,perp-HOONO calculated at the MP2 level of theory. ¹⁰ A computational

study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculated by summing various contributions calculated at the CCSD(T) level with the use of various basis sets, led to $\Delta_f H_0^\circ = -6.4 \pm 2.0$ kJ mol⁻¹, $\Delta_f H_{298}^\circ = -15.5 \pm 2.0$ kJ mol⁻¹, and $S = 271.0 \pm 2.0$ J K⁻¹ mol⁻¹.¹³

***trans, perp*-HOONO**

Derived from the dissociation energy for *t,p*-HOONO and reported molecular constants (Table 3-1, Note 1). Enthalpy values for the *cis,cis*-, *cis,perp*-, and *trans,perp*-HOONO have also been calculated at the MP2 level of theory.¹⁰

HO₂NO₂ Derived from a third-law analysis of the equilibrium constant for HO₂NO₂ ↔ HO₂ + NO₂.⁶ Previous recommended enthalpy value of -12.7 ± 0.6 kcal mol⁻¹ from Regimbal and Mozurkewich.¹¹ A value of $\Delta_f H_{298}^\circ = -52.3$ kJ mol⁻¹ was obtained from a computational study in which equilibrium structures optimized at the MP2 level with the 6-311G(d,p) basis set and enthalpy values calculated by both atomization energies and through use of isodesmic reactions at the G3, G3B3, and G4 methods.³ A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculated by summing various contributions calculated at the CCSD(T) level with the use of various basis sets, led to $\Delta_f H_0^\circ = -41.3 \pm 2.4$ kJ mol⁻¹, $\Delta_f H_{298}^\circ = -52.4 \pm 2.4$ kJ mol⁻¹, and $S = 296.2 \pm 2.0$ J K⁻¹ mol⁻¹.¹³ The enthalpy difference was used to calculate the 0 K value in the Table.

NH₄NO₃ Enthalpy obtained from a third-law analysis of the sublimation pressure of NH₄NO₃ over the range 321–360 K. The entropy was calculated from molecular constants taken from the literature.⁸ A high-level theoretical calculation, CCSD(T) extrapolated to the aug-cc-pV ∞ Z basis set, gives $\Delta_f H_0^\circ = -221.1 \pm 3$ kJ mol⁻¹, $\Delta_f H_{298}^\circ = -230.6 \pm 3$ kJ mol⁻¹, and $S = 342.4$ J K⁻¹ mol⁻¹.⁹

- | | |
|--|--|
| C | CODATA Key Value. ² The JANAF Tables give $\Delta_f H_0^\circ = 711.2 \text{ kJ mol}^{-1}$, $\Delta_f H_{298}^\circ = 716.7 \text{ kJ mol}^{-1}$, and $S^\circ = 158.100 \text{ J K}^{-1} \text{ mol}^{-1}$. ¹ |
| CH | Recommendation taken from IUPAC Task Group. ⁹ Previous recommendation of $\Delta H_f(298 \text{ K}) = 597.37 \pm 1.3 \text{ kJ mol}^{-1}$ was from Gurvich et al. ⁶ The preferred value corresponds to the theoretical value of Császár et al., ⁴ which is in agreement with the experimental values but is considered to be of higher accuracy. The entropy was taken from Gurvich et al. ⁶ A network optimization of <i>ab initio</i> reaction enthalpies results in a value of $\Delta_f H_0^\circ = 592.62 \pm 0.24 \text{ kJ mol}^{-1}$. ³ The uncertainty corresponds to the 95% confidence limit. The reference atomic values were taken from the Active Thermochemical Tables, ver. 1.20. |
| CH₂(³B₁) | Update to the recommendation from IUPAC Task Group. ¹⁰ Previous recommendations of $\Delta H_f(298 \text{ K}) = 390.4 \pm 0.8 \text{ kJ mol}^{-1}$ and $S(298 \text{ K}) = 194.90 \text{ J K}^{-1} \text{ mol}^{-1}$ were from experiments of Ruscic et al. ¹¹ The present enthalpy recommendation represents a weighted average of this and other experimental results; the higher uncertainty reflects this and the differences between measurements that relate methylene to methyl and those derived from the dissociation of ketene. A network optimization of <i>ab initio</i> reaction enthalpies results in a value of $\Delta_f H_0^\circ = 390.86 \pm 0.29 \text{ kJ mol}^{-1}$. ³ The uncertainty corresponds to the 95% confidence limit. The reference atomic values were taken from the Active Thermochemical Tables, ver. 1.20. |
| CH₂(¹A₁) | Update to the recommendation taken from IUPAC Task Group. ¹⁰ Previous recommendation of $\Delta H_f(298 \text{ K}) = 428.0 \pm 0.8 \text{ kJ mol}^{-1}$ was from Jacox. ⁷ The preferred value is based on the enthalpy of formation of triplet methylene and a separation between the singlet and triplet states of $3147 \pm 5 \text{ cm}^{-1}$. |
| CH₃ | Recommendation taken from IUPAC Task Group. ⁹ Entropy value differs only slightly from previously recommended value of $193.96 \text{ J K}^{-1} \text{ mol}^{-1}$ from Gurvich et al. ⁶ A network optimization of <i>ab initio</i> reaction enthalpies results in a value of $\Delta_f H_0^\circ = 149.66 \pm 0.34 \text{ kJ mol}^{-1}$. ³ The uncertainty corresponds to the 95% confidence limit. The reference atomic values were taken from the Active Thermochemical Tables, ver. 1.20. |
| CH₄ | Enthalpy from an active thermochemical tables optimization. ¹² Enthalpy from flame calorimetry $-74.48 \pm 0.41 \text{ kJ mol}^{-1}$ used previously. ⁸ Entropy from Frenkel et al. ⁵ A network optimization of <i>ab initio</i> reaction enthalpies results in a value of $\Delta_f H_0^\circ = -66.35 \pm 0.46 \text{ kJ mol}^{-1}$. ³ The uncertainty corresponds to the 95% confidence limit. The reference atomic values were taken from the Active Thermochemical Tables, ver. 1.20. |

[Back to Table](#)

- CO** CODATA Key Value.³ Atomization energies calculated using CCSD(T) with aug cc-pVnZ (n = D – 7) basis sets, using frozen-core CCSD(T) optimized geometries and extrapolated to the complete basis set limit, led to enthalpies of $\Delta_f H_0^\circ = -27.0 \pm 0.2$ kcal mol⁻¹ and $\Delta_f H_{298}^\circ = -26.2 \pm 0.2$ kcal mol⁻¹.¹² A network optimization of *ab initio* reaction enthalpies results in a value of $\Delta_f H_0^\circ = -114.09 \pm 0.32$ kJ mol⁻¹.⁴ The uncertainty corresponds to the 95% confidence limit. The reference atomic values were taken from the Active Thermochemical Tables, ver. 1.20.
- CO₂** CODATA Key Value.³ The active thermochemical tables optimization gives $\Delta_f H_{298}^\circ = -393.474 \pm 0.014$ kJ mol⁻¹ and $\Delta_f H_0^\circ = -393.108 \pm 0.014$ kJ mol⁻¹.²⁴ Atomization energies calculated using CCSD(T) with aug cc-pVnZ (n=D – 7) basis sets, using frozen-core CCSD(T) optimized geometries and extrapolated to the complete basis set limit, led to enthalpies of $\Delta_f H_0^\circ = -93.7 \pm 0.2$ kcal mol⁻¹ and $\Delta_f H_{298}^\circ = -93.8 \pm 0.2$ kcal mol⁻¹.¹² A network optimization of *ab initio* reaction enthalpies results in a value of $\Delta_f H_0^\circ = -392.98 \pm 0.40$ kJ mol⁻¹.⁴ The uncertainty corresponds to the 95% confidence limit. The reference atomic values were taken from the Active Thermochemical Tables, ver. 1.20.
- HCO** Enthalpy from reversible reactions of I and Br with CH₂O,¹ using present values for HI and HBr. Entropy taken from Gurvich et al.¹³ Atomization energies calculated using CCSD(T) with aug cc-pVnZ (n=D – 7) basis sets, using frozen-core CCSD(T) optimized geometries and extrapolated to the complete basis set limit, led to enthalpies of $\Delta_f H_0^\circ = 10.4 \pm 0.2$ kcal mol⁻¹ and $\Delta_f H_{298}^\circ = 10.5 \pm 0.2$ kcal mol⁻¹.¹²
- CH₂O** Enthalpy at 298 K obtained by using experimental reaction enthalpies taken from the literature.⁷ This value was confirmed by three computational approaches involving enthalpies of the same reaction, isodesmic reaction enthalpies, and atomization energies, using a range of high-level computational techniques. The previous value, $\Delta_f H_{298}^\circ = -108.7 \pm 0.50$ kJ mol⁻¹, was taken from review of Gurvich et al., as is the present entropy value and enthalpy difference.¹³ A CCSD(T) calculation with the aug-cc-pVnZ (n = D,T,Q,5) basis set extrapolated to the CBS limit gave $\Delta_f H_0^\circ = -104.2 \pm 2.1$ kJ mol⁻¹, $\Delta_f H_{298}^\circ = -107.95 \pm 2.1$ kJ mol⁻¹, and $S = 218.57$ J K⁻¹ mol⁻¹.²⁰ A computation using the focal-point analysis approach resulted in $\Delta_f H_0^\circ = -105.42 \pm 0.33$ kJ mol⁻¹, $\Delta_f H_{298}^\circ = -109.23 \pm 0.33$ kJ mol⁻¹.⁵

***trans*-HOCO**

The enthalpy and entropy values are taken from a CCSDT(Q) calculation, with structure optimized using the cc-pVQZ basis set.²¹ The previous $\Delta_f H_{298}^\circ = -187.9 \pm 2.1$ was obtained from atomization energies calculated using CCSD(T) with aug cc-pVnZ (n=D – 7) basis sets, using frozen-core CCSD(T) optimized geometries and extrapolated to the complete basis set limit.¹² An earlier computational study using G3 and CBS-QB3 methods gave $\Delta_f H_{298}^\circ = -43.3 \pm 2$ kcal mol⁻¹.¹⁰ These results are in agreement with photoionization lower limit of -46.5 kcal mol⁻¹.²⁵

***cis*-HOCO** The enthalpy and entropy values are taken from a CCSDT(Q) calculation, with structure optimized using the cc-pVQZ basis set.²¹ The previous $\Delta_f H_{298}^\circ = -175.7 \pm 2.1$ was obtained from atomization energies calculated using CCSD(T) with aug cc-pVnZ (n=D – 7) basis sets, using frozen-core CCSD(T) optimized geometries and extrapolated to the complete basis set limit; $\Delta_f H_0^\circ = -41.0 \pm 0.5$ kcal mol⁻¹. (Result presented in text as an energy difference of 2.9 kcal mol⁻¹ over the *trans* form.)¹² An earlier computational study using G3 and CBS-Qb3 methods gave $\Delta_f H_{298}^\circ = -41.4 \pm 2$ kcal mol⁻¹.¹⁰

HC(O)O Enthalpy obtained from atomization energies calculated using CCSD(T) with aug cc-pVnZ (n = D – 7) basis sets, using frozen-core CCSD(T) optimized geometries and extrapolated to the complete basis set limit.¹² An earlier study using vibrational frequencies calculated at the HF/6-31G(D) level and total energies evaluated at the G2(MP2) level, also making use of isodesmic reactions, gave $\Delta_f H_{298}^\circ = -30$ kcal mol⁻¹ and the quoted entropy value.³⁰ A CCSD(T)-CBS (W1U) calculation gives $\Delta_f H_{298}^\circ = -129.4 \pm 12.6$ kJ mol⁻¹.¹¹

C(O)OH Vibrational frequencies calculated at the HF/6-31G(D) level and total energies evaluated at the G2(MP2) level, also making use of isodesmic reactions.³⁰ Enthalpy calculated using the atomization energy method at the CBS-Q level gave -41.62 kcal mol⁻¹.²⁷

HC(O)OH Enthalpy taken from NBS Tables;²⁹ entropy calculated based on structure optimized at MP2/6-31G(D) and frequencies calculated at HF6/31G(D) level.³⁰ See also discussion of enthalpy in Yu et al.³⁰ $\Delta_f H_{298}^\circ = -90.5$ kcal mol⁻¹ also obtained by calculating optimized geometry at the CCSD(T)/aVTZ level with the aug-cc-pVTZ basis set; CCSD(T) energy extrapolated to the CBS limit.²² Atomization energies calculated using CCSD(T) with aug cc-pVnZ (n = D – 7) basis sets, using frozen-core CCSD(T) optimized geometries and extrapolated to the complete basis set limit, led to enthalpies of $\Delta_f H_0^\circ = -88.9 \pm 0.4$ kcal mol⁻¹ and $\Delta_f H_{298}^\circ = -90.7 \pm 0.4$ kcal mol⁻¹.¹² Microwave intensity measurements have determined that the *cis* rotamer of HC(O)OH to be 16.3 ± 0.4 kJ mol⁻¹ higher in energy than the *trans* rotamer.¹⁴

***trans*-and *cis*-HC(O)OO**

Photoelectron spectroscopy of the peroxyformate anion was used to obtain the electron affinity of the peroxyformate radical. Through a thermochemical cycle, this leads to the O-H bond dissociation energy, which combined with the calculated enthalpy of the acid, yields the enthalpy of formation. BDEs for both the *cis* and *trans* conformers of the acid could be determined, both leading to the lower-energy *trans* conformer of the radical.²⁸

***trans*-HC(O)OOH**

Enthalpy obtained from the calculated heat of an isodesmic reaction, at the G3B3MP2 level of theory.²⁸ This value is slightly lower than $\Delta_f H_{298}^\circ = -285.3 \pm 2.5$ kJ mol⁻¹ ($\Delta_f H_0^\circ = -275.7$ kJ mol⁻¹) obtained from atomization energies calculated using CCSD(T) with aug cc-pVnZ (n = D – 7) basis sets, using frozen-core CCSD(T) optimized geometries and extrapolated to the complete basis set limit.¹² The present value was chosen as it is conformer specific; the 0 K value is based on the Feller et al.¹² enthalpy difference.

***cis*-HC(O)OOH**

The enthalpy value is derived from the value for the *trans* conformer, which is calculated at the G3B3MP2 level of theory, to be 14.2 kJ mol⁻¹ lower in energy than the *cis* conformer.²⁸

CH₂OO, formaldehyde carbonyl oxide (Criegee intermediate)

Optimized geometry calculated at the CCSD(T)/aVTZ level with the aug-cc-pVTZ basis set; CCSD(T) energy extrapolated to the CBS limit.²²

CH₂O₂, dioxirane

Optimized geometry calculated at the CCSD(T)/aVTZ level with the aug-cc-pVTZ basis set; CCSD(T) energy extrapolated to the CBS limit.²²

CH₃O Selection taken from IUPAC Task Group.²³ The recommended enthalpy is a weighted average of the experimental determinations, with an amplified uncertainty for the older gas-phase acidity determinations. The recommendation is supported by one recent high-level theoretical study. This value is significantly higher than that recommended here previously, 17.15±3.8 kJ mol⁻¹ from the evaluation of Berkowitz et al.,² and most other previous recommendations. The recommended entropy is also somewhat different than the previously recommended value of 232.86 J K⁻¹ mol⁻¹.¹³ Atomization energies calculated using CCSD(T) with cc-pVnZ (n = D, T, and Q) basis sets, using (U)MP2/aug-cc-pVTZ optimized geometries and extrapolated to the complete basis set limit, led to enthalpies of $\Delta_f H_0^0 = 7.4$ kcal mol⁻¹ and $\Delta_f H_{298}^0 = 5.5$ kcal mol⁻¹.¹⁹

CH₃O₂ Based on a re-analysis of previous equilibrium data on R + O₂ ↔ RO₂ from the same laboratory.¹⁶ In a computational study, $\Delta_f H_{298}^0 = 8.8$ kJ mol⁻¹ was determined using G3B3 and CBS-APNO methods with isodesmic reactions to minimize systematic errors, where the geometry was optimized at the B3LYP/cc-pVTZ+d level of theory. This work also provided the recommended entropy.⁶

CH₂OH Recommendation taken from IUPAC Task Group.²³ Enthalpy is a weighted average of the most recent experimental studies and a theoretical study, and is in good agreement with all the previous experimental results. (Note that the previous value listed in this Table, $\Delta_f H_0^0 = -11.5 \pm 1.3$ kJ mol⁻¹, was inadvertently for 0 K.) The entropy value reported by Johnson and Hudgens was accepted and is included here with their error limits.¹⁵ Results of Dóbbé, et al.⁸ give -16.6 ± 1.3 kJ mol⁻¹. Atomization energies calculated using CCSD(T) with cc-pVnZ (n=D, T, and Q) basis sets, using (U)MP2/aug-cc-pVTZ optimized geometries and extrapolated to the complete basis set limit, led to enthalpies of $\Delta_f H_0^0 = -2.3$ kcal mol⁻¹ and $\Delta_f H_{298}^0 = -3.8$ kcal mol⁻¹.¹⁹

CH₃OH Taken from review of Gurvich et al.¹³ Atomization energies calculated using CCSD(T) with cc-pVnZ (n = D, T, and Q) basis sets, using (U)MP2/aug-cc-pVTZ optimized geometries and extrapolated to the complete basis set limit, led to enthalpies of $\Delta_f H_0^0 = -45.7$ kcal mol⁻¹ and $\Delta_f H_{298}^0 = -48.3$ kcal mol⁻¹.¹⁹

CH₃OH•HO₂

Estimated from studies on the decay of HO₂ in the presence of CH₃OH, with supporting *ab initio* calculations (Table 3-1, Note 5).

CH₂OOH Calculated using the complete basis set method, CBS-Q. Enthalpies calculated using the atomization energy method. Entropy based on geometric properties optimized at the MP2/6-31G(d') level and vibrational frequencies at the HF/6-31G(d') level.²⁷ This radical is unstable to decomposition to CH₂O + OH.

CH₃OOH Geometry optimization and frequency calculations were performed at the MP2/6-31G(d) and the B3LYP/6-311++G(d,p) levels of theory, with a single-point energy calculation at the CCSD(T)/6-311++G(d,p)/B3LYP/6-311++G(d,p) level. The dissociation energy into HO₂ and the alkyl radical was then evaluated and used, after thermal correction, to calculate the enthalpy of formation at 298 K.¹⁷ This was adjusted to the radical values from the present Table. Reaction enthalpies determined using the G2 method indicated $\Delta H_{298}^0(\text{CH}_3\text{OO}-\text{H})$ is 1.6 kcal mol⁻¹ lower than $\Delta H_{298}^0(\text{HOO}-\text{H})$, or 85.9 kcal mol⁻¹ (359.4 kJ mol⁻¹), leading to the previous enthalpy value of -132.2 kJ mol⁻¹.¹⁸ An earlier recommended enthalpy value (-139.0 ± 8.1 kJ mol⁻¹) was computed on the assumption that the dissociation energy for ROO-H is 366±3 kJ mol⁻¹ (Stocker and Pilling, unpublished work).¹⁶ Enthalpy calculated using the atomization energy method at the CBS-Q level gave -30.75 kcal mol⁻¹ (-128.7 kJ

mol⁻¹).²⁷ The entropy and enthalpy difference is from the updated JANAF Table.⁹ An entropy value of 273.4 J K⁻¹ mol⁻¹ was calculated based on geometric properties optimized at the MP2/6-31G(d') level and vibrational frequencies at the HF/6-31G(d') level.²⁷ Calculations using the CBS-QB3 and CBS-APNO model chemistries on three isodesmic reactions led to $\Delta_f H_{298}^\circ = -129.5 \pm 0.9$ kJ mol⁻¹.²⁶

CH₃O₃ and CH₃O₄

Bond dissociation energies were calculated for CH₃OOOOCH₃ at the G3B3 and CBS-APNO levels of theory, using isodesmic and bond dissociation work reactions. The molecular geometry was optimized at the B3LYP/cc-pVTZ+d level of theory.⁶

[Back to Table](#)

CN, HCN, and C₂N₂

From the review of Gurvich et al.⁵

CH₂NH₂ Based on recommendation of McMillen et al.,⁸ adjusted for enthalpy for CH₃NH₂ used here (−5.6 kcal mol^{−1} vs. −5.5 kcal mol^{−1}). Calculations at the G2(MP2) level lead to an enthalpy of 147 kJ mol^{−1}.¹¹

CH₃NH₂ Enthalpy from review of Pedley;⁹ entropy value from the Thermodynamics Research Center Data Series.⁴ Values of Δ_fH₂₉₈⁰ = 21.8 ± 1.5 kJ mol^{−1} and Δ_fH₀⁰ = −7.0 ± 1.5 kJ mol^{−1} have been derived from a threshold PEPICO study of alkyl amines and the use of two isodesmic reaction networks, connected through the TPEPICO dissociation energies, and with reaction heats calculated at the CBS-APNO and W1U levels of theory.²

- CH₂CN** Based on an analysis of the negative ion cycle.⁷
- CH₃CN** Enthalpy at 298 K by combustion calorimetry;¹ 0 K value based on measured vibrational frequencies.⁷ Entropy from NBS Tables.¹⁰
- CH₂N₂** Enthalpy value calculated from the atomization energy at the G3 level of theory. Calculations also carried out at the G2, G2M(CC5), B3LYP, MW1B95, and MPWB1K levels.⁶
- CH₂N₂** Enthalpy from a CCSD(T) calculation of the atomization energy.³

- CH₂NO** From computed G2 heats of reaction.¹¹
- NH₂CO** This is the more stable isomer of CH₂NO (above), which is formed by the association of CH₂ with NO. The enthalpy and entropy values are taken from a CCSDT(Q) calculation, with structure optimized using the cc-pVQZ basis set.⁸ The previous $\Delta_f H_{298}^0 = -15.1 \pm 4$ was from computed G2 heats of reaction.¹¹
- NCO** Enthalpy from D(H-NCO) = 4.9±0.01 eV,⁹ using present value for HNCO. Entropy from Gurvich et al.⁶
- HNCO, isocyanic acid**
The dissociative photoionization of urea was investigated by iPEPICO.² The lowest energy channel, CO(NH₂)₂ + hν → NH₃⁺ + HNCO + e⁻, was measured accurately and the appearance energy of the second channel, CO(NH₂)₂ + hν → NH₂ + H₂NCO⁺ + e⁻, was measured with somewhat lower precision. These were used together with W1 and CBS-APNO calculations

on three isodesmic reactions for $\text{CO}(\text{NH}_2)_2$ and two isoelectronic reactions for HNCO to determine the enthalpy values for both HNCO and $\text{CO}(\text{NH}_2)_2$. The previous value, $\Delta_f H_{298}^\circ = -104 \pm 12 \text{ kJ mol}^{-1}$ from threshold photodissociation of HNCO by measuring $\text{NH}(\text{a}^1\Delta)$ threshold and fragment energy, adjusted for the present enthalpy of NH .¹² Entropy from NBS Tables.¹⁴

HCONH₂, Formamide

From review of Pedley et al.¹⁰

- CH₂NO₂** Recommendation from the Thermodynamics Research Center Data Series.⁵ A calculation of the atomization energy at the G3 level of theory leads to $\Delta_f H_{298}^\circ = 31.5 \text{ kcal mol}^{-1}$. Calculations also carried out at the G2, G2M(CC5), B3LYP, MW1B95, and MPWB1K levels.⁷
- CH₃NO₂** Enthalpy from Pedley,¹⁰ entropy from Frenkel et al.⁵ Enthalpy value calculated using G3, CBS-QB3, and CBS-APNO methods applied to atomization, isomerization, and work reactions is $\Delta_f H_{298}^\circ = -17.67 \pm 0.27 \text{ kcal mol}^{-1}$, which becomes $-17.73 \pm 0.27 \text{ kcal mol}^{-1}$ using the reference enthalpy for *cis*-HONO from this Table.¹ A calculation of the atomization energy at the G3 level of theory leads to $\Delta_f H_{298}^\circ = -17.5 \text{ kcal mol}^{-1}$. Calculations also carried out at the G2, G2M(CC5), B3LYP, MW1B95, and MPWB1K levels.⁷ A value of $\Delta_f H_{298}^\circ = -73.2 \text{ kJ mol}^{-1}$ was calculated at the G4 level of theory, making use of isodesmic reactions.⁴
- CH₃ONO** Taken from review of Stull et al.¹³ Enthalpy value calculated using G3, CBS-QB3, and CBS-APNO methods applied to atomization, isomerization, and work reactions is $\Delta_f H_{298}^\circ = -15.64 \pm 0.10 \text{ kcal mol}^{-1}$, which becomes $-15.81 \pm 0.10 \text{ kcal mol}^{-1}$ using the reference enthalpy for *cis*-HONO from this Table.¹ A calculation of the atomization energy at the G3 level of theory leads to $\Delta_f H_{298}^\circ = -15.4 \text{ kcal mol}^{-1}$. Calculations also carried out at the G2, G2M(CC5), B3LYP, MW1B95, and MPWB1K levels.⁷
- CH₃ONO₂** Enthalpy from Pedley,¹⁰ entropy from Stull et al.¹³
- CH₃O₂NO₂** Equilibrium structures optimized at the MP2 level with the 6-311G(d,p) basis set and enthalpy values calculated by both atomization energies and through use of isodesmic reactions at the G3, G3B3, and G4 methods.³

(NH₂)₂CO, Urea

The dissociative photoionization of urea was investigated by iPEPICO.² The lowest energy channel, $\text{CO}(\text{NH}_2)_2 + h\nu \rightarrow \text{NH}_3^+ + \text{HNCO} + e^-$, was measured accurately and the appearance energy of the second channel, $\text{CO}(\text{NH}_2)_2 + h\nu \rightarrow \text{NH}_2 + \text{H}_2\text{NCO}^+ + e^-$, was measured with somewhat lower precision. These were used together with W1 and CBS-APNO calculations on three isodesmic reactions for $\text{CO}(\text{NH}_2)_2$ and two isoelectronic reactions for HNCO to determine the enthalpy values for both HNCO and $\text{CO}(\text{NH}_2)_2$. The previous value, $\Delta_f H_{298}^\circ = -245.8 \pm 2.0 \text{ kJ mol}^{-1}$ from Pedley et al.,¹⁰ depended on a value of the sublimation energy that appears to be too low.²

- C(NO₂)₄** Enthalpy value calculated from the atomization energy at the G3 level of theory. Calculations also carried out at the G2, G2M(CC5), B3LYP, MW1B95, and MPWB1K levels.⁷ (see addition and corrections)

[Back to Table](#)

- C₂** The enthalpy value is the result of an optimization in the Active Thermochemical Tables (ATcT).¹² The entropy value is from JANAF.³
- C₂H** Enthalpy from review of Berkowitz, Ellison, and Gutman.¹ Δ_fH₀^o = 134.1±0.7 kcal mol⁻¹. Entropy from Gurvich et al.⁶ High level *ab initio* calculations result in an enthalpy value of 567.4±1.5 kJ mol⁻¹.¹⁴
- C₂H₂** From the review of Gurvich et al.⁶ Pedley gives the enthalpy as 228.2±0.7 kJ mol⁻¹.¹⁰ The JANAF Tables give Δ_fH₀^o = 227.3 kJ mol⁻¹, Δ_fH₂₉₈^o = 226.7 kJ mol⁻¹, and S^o = 200.958 J K⁻¹ mol⁻¹.³ A network optimization of *ab initio* reaction enthalpies results in a value of Δ_fH₀^o = 228.67±0.35 kJ mol⁻¹.⁴ The uncertainty corresponds to the 95% confidence limit. The reference atomic values were taken from the Active Thermochemical Tables, ver. 1.20.

H₂CC, vinylidene

Based on a series of negative ion photoelectron spectroscopic measurements combined with proton-transfer kinetics.⁵ CCSD(T) calculations, extrapolated to the CBS level, lead to Δ_fH₀^o = 98.6 kcal mol⁻¹ and Δ_fH₂₉₈^o = 98.8 kcal mol⁻¹.⁹

- C₂H₃** Enthalpy derived from a third-law analysis of the reaction $\text{Cl} + \text{C}_2\text{H}_4 \leftrightarrow \text{HCl} + \text{C}_2\text{H}_3$.⁷ A second-law analysis gives $69.1 \pm 1.6 \text{ kcal mol}^{-1}$. The recommendation of Tsang is $71.5 \pm 1 \text{ kcal mol}^{-1}$.¹⁶ See also discussion by Lago and Baer.⁸ Negative ion photoelectron spectroscopy combined with proton-transfer kinetics leads to a value of $\Delta_f H_{298}^\circ = 71.6 \pm 0.8 \text{ kcal mol}^{-1}$.⁵ A calculation at the HEAT345-Q level of theory gives recommended values of $\Delta_f H_0^\circ = 301.5 \pm 1.3 \text{ kJ mol}^{-1}$ and $\Delta_f H_{298}^\circ = 297.3 \pm 1.3 \text{ kJ mol}^{-1}$.¹⁵ This enthalpy difference provides the 0 K value in the Table. The entropy value was taken from the evaluation of Tsang.¹⁶
- C₂H₄** From the review of Gurvich et al.⁶ The JANAF Tables give $\Delta_f H_0^\circ = 60.0 \text{ kJ mol}^{-1}$, $\Delta_f H_{298}^\circ = 52.5 \text{ kJ mol}^{-1}$, and $S^\circ = 219.330 \text{ J K}^{-1} \text{ mol}^{-1}$.³
- C₂H₅** Enthalpy from review of Berkowitz, Ellison, and Gutman.¹ Entropy from Gurvich et al.⁶ Enthalpy of $120.7 \pm 1.0 \text{ kJ mol}^{-1}$ has been derived from a threshold PEPICO study of alkyl amines and the use of two isodesmic reaction networks, connected through the TPEPICO dissociation energies, and with reaction heats calculated at the CBS-APNO and W1U levels of theory. $\Delta_f H_0^\circ = 132.3 \pm 1.0 \text{ kJ mol}^{-1}$.² A re-analysis of the thermal decomposition of $\text{C}_2\text{H}_5\text{I}$, making use of calculated molecular parameters, led to a value of $\Delta_f H_{298}^\circ = 124 \pm 3 \text{ kJ mol}^{-1}$.¹³
- C₂H₆** Enthalpy from flame calorimetry measurement.¹¹ Entropy from Gurvich et al.,⁶ who gives $\Delta_f H_{298}^\circ = -84.00 \pm 0.40 \text{ kJ mol}^{-1}$ and $\Delta_f H_0^\circ = -68.38 \pm 0.40 \text{ kJ mol}^{-1}$.

Note 12: *Compounds containing two C, one O, and 1-6 H*

[Back to Table](#)

- CHCO** Based on the recommended dissociation energy for CH₂CO of 105.3±2.1 kcal mol⁻¹.¹ High level *ab initio* calculations result in an enthalpy of 173.8±1.5 kJ mol⁻¹.²⁰
- CH₂CO** From photoionization of CH₂CO and a subsequent optimization of a local thermochemical network.¹⁷ Calculations on several isodesmic reactions using CBS-QB3, CBS-APNO, and G3 methods led to a value of $\Delta_f H_{298}^\circ = -48.2 \pm 2.6$ kJ mol⁻¹.¹⁸
- CH₃CO** Recommendation taken from IUPAC Task Group.¹⁶ Enthalpy is a weighted average of the experimental results, with amplified uncertainties assigned to the most negative values. This recommendation is only slightly lower than the value -10.0±1.2 kJ mol⁻¹ previously recommended here.¹
- C₂H₂OH** Calculated from the heat of reactions for OH + C₂H₂ of -146±10 kJ mol⁻¹.⁷
- CH₂C(O)H, vinoxy radical**
Enthalpy values calculated at the HEAT345-Q level of theory.²¹ Previous enthalpy value an average of the a value obtained from the gas-phase basicity and proton affinity determined by a kinetic method (9.9±3.9 kJ mol⁻¹) and a reexamination of the results of Holmes, et al.¹¹ on the dissociation of ethyl acetate after electron ionization (15.9±5.6 kJ mol⁻¹).³ This value is supported by several computational studies.^{5,9,10,12} Previous recommendation, 10.5±9.2 kJ mol⁻¹, was from an analysis of gas-phase acidity and electron affinity studies.¹ A G3MP2B3 calculation led to $\Delta_f H_{298}^\circ = 13.45$ kJ mol⁻¹ and the selected entropy value.¹²
- CH₃C(O)H**
Enthalpy from Pedley,¹⁵ entropy from Frenkel et al.⁶
- Vinyl alcohol and corresponding radicals (CH₂CHOH, CH₂COH, CHCHOH)**
Molecular geometry optimized at the B3LYP/6-31G(d,p) level of theory. The enthalpy was determined using CBS-Q, CBS-APNO, and G3 methods with isodesmic reactions to minimize systematic errors. Entropies calculated by using the SMCPS program. The enthalpy values for both conformers of vinyl alcohol are within about 5 kJ mol⁻¹ the average of the experimental values, which are based on ionization techniques.⁴
- CH₃CH₂O** Recommendation taken from IUPAC Task Group.¹⁶ Enthalpy is based on a collision-induced dissociation measurement, which lies between the theoretical results and most of the previous recommendations, including that previously included here, $\Delta_f H_{298}^\circ = -15.5 \pm 3.3$ kJ mol⁻¹.¹ Ruscic et al. note that their new preferred value corresponds to an O–H bond dissociation energy for ethanol more in line with that in methanol. Atomization energies calculated using CCSD(T) with cc-pVnZ (n = D, T, and Q) basis sets, using (U)MP2/aug-cc-pVTZ optimized geometries and extrapolated to the complete basis set limit, led to enthalpies of $\Delta_f H_0^\circ = 0.8$ kcal mol⁻¹ and $\Delta_f H_{298}^\circ = -2.7$ kcal mol⁻¹.¹³
- CH₂CH₂OH**
Calculated from the heat of reaction for the addition of OH to C₂H₄ of -123±6 kJ mol⁻¹.⁷ Atomization energies calculated using CCSD(T) with cc-pVnZ (n = D, T, and Q) basis sets, using (U)MP2/aug-cc-pVTZ optimized geometries and extrapolated to the complete basis set limit, led to enthalpies of $\Delta_f H_0^\circ = -3.1$ kcal mol⁻¹ and $\Delta_f H_{298}^\circ = -6.2$ kcal mol⁻¹.¹³ The enthalpy of formation was also calculated from a set of isodesmic and isogyric

reactions at the CBS-QB3 level of theory to be $\Delta_f H_{298}^\circ = -28.7 \pm 2.2 \text{ kJ mol}^{-1}$. Calculations with B3LYP/cc-pVTZ were about 6 kJ mol^{-1} more negative.²

CH₃CHOH

Calculated using the complete basis set method, CBS-Q. Enthalpies calculated using the atomization energy method. Entropy based on geometric properties optimized at the MP2/6-31G(d') level and vibrational frequencies at the HF/6-31G(d') level.¹⁹ Enthalpy recommended in the review of McMillen and Golden is $-15.2 \pm 1 \text{ kcal mol}^{-1}$.¹⁴ Atomization energies calculated using CCSD(T) with cc-pVnZ (n = D, T, and Q) basis sets, using (U)MP2/aug-cc-pVTZ optimized geometries and extrapolated to the complete basis set limit, led to enthalpies of $\Delta_f H_0^\circ = -9.8 \text{ kcal mol}^{-1}$ and $\Delta_f H_{298}^\circ = -13.1 \text{ kcal mol}^{-1}$.¹³

C₂H₅OH

Taken from review of Gurvich, et al.⁸ Atomization energies calculated using CCSD(T) with cc-pVnZ (n = D, T, and Q) basis sets, using (U)MP2/aug-cc-pVTZ optimized geometries and extrapolated to the complete basis set limit, led to enthalpies of $\Delta_f H_0^\circ = -52.1 \text{ kcal mol}^{-1}$ and $\Delta_f H_{298}^\circ = -56.4 \text{ kcal mol}^{-1}$.¹³

CH₃OCH₂

Calculated using the complete basis set method, CBS-Q. Enthalpies calculated using the atomization energy method. Entropy based on geometric properties optimized at the MP2/6-31G(d') level and vibrational frequencies at the HF/6-31G(d') level.¹⁹ Recommendation in the review of McMillen and Golden, adjusted to allow for present enthalpy of CH₃COCH₃, is $-3 \pm 1 \text{ kcal mol}^{-1}$.¹⁴

CH₃OCH₃

Enthalpy from Pedley,¹⁵ entropy from Frenkel et al.⁶ Enthalpy calculated using the atomization energy method at the CBS-Q level gave $-43.98 \text{ kcal mol}^{-1}$.¹⁹

Note 13: Compounds containing two C, two O, and 1-6 H

[Back to Table](#)

(CHO)₂, glyoxal

The lowest energy conformer is the *trans* isomer. From the updated JANAF Tables, based on measurements of the heat of combustion.²

cy-(C₂H₂O)O, oxiranone (an α -lactone of ethylene oxide)

Ab initio calculations utilizing isodesmic reactions.⁹

CH₃CHOOH

Calculated using the complete basis set method, CBS-Q. Enthalpies calculated using the atomization energy method. Entropy based on geometric properties optimized at the MP2/6-31G(d') level and vibrational frequencies at the HF/6-31G(d') level.¹² This radical is unstable towards dissociation.

C₂H₅O₂ Based on a re-analysis of previous equilibrium data on R + O₂ $\leftrightarrow$ RO₂ from the same laboratory.⁵

C₂H₅OOH Reaction enthalpy for the reaction CH₃CH₂OO + CH₃OOH $\rightarrow$ CH₃CH₂OOH + CH₃OO calculated to be 0.5 kcal mol⁻¹ using the QCISD(T)/6-31G**// MP2/6-31G* method.⁶ Previous enthalpy value (-175.4 $\pm$ 12.9 kJ mol⁻¹) was computed on the assumption that the dissociation energy for ROO-H is 366 $\pm$ 3 kJ mol⁻¹ (Stocker and Pilling, unpublished work).⁵ Pedley gives a value of -198.9 $\pm$ 58.7 kJ mol⁻¹.⁸ Enthalpy calculated using the atomization energy method at the CBS-Q level gave -38.78 kcal mol⁻¹.¹² Calculations using the CBS-QB3 and CBS-APNO model chemistries on three isodesmic reactions led to $\Delta_f H_{298}^\circ = -163.7 \pm 0.9$ kJ mol⁻¹.¹¹ Entropy based on geometric properties optimized at the MP2/6-31G(d') level and vibrational frequencies at the HF/6-31G(d') level.¹²

CH₃OCO, radical from methyl formate

An average of two isodesmic reactions calculated at the G3MP2//B3LYP/6-31G(d) level.¹⁰ Enthalpy calculated using the atomization energy method at the CBS-Q level gave $\Delta_f H_{298}^\circ = -37.87 \text{ kcal mol}^{-1}$.¹² Entropy based on geometric properties optimized at the MP2/6-31G(d') level and vibrational frequencies at the HF/6-31G(d') level.¹²

CH₂OC(O)H

Calculated using the complete basis set method, CBS-Q. Enthalpies calculated using the atomization energy method. Entropy based on geometric properties optimized at the MP2/6-31G(d') level and vibrational frequencies at the HF/6-31G(d') level.¹²

CH₃OC(O)H, methyl formate

Enthalpy value taken from review of Pedley.⁸ An average of three isodesmic reactions calculated at the G3MP2//B3LYP/6-31G(d) level, supported by G3 and B3LYP calculations gives $\Delta_f H_{298}^\circ = -82.3 \pm 0.49 \text{ kcal mol}^{-1}$.¹⁰ Enthalpy calculated using the atomization energy method at the CBS-Q level gave $\Delta_f H_{298}^\circ = -85.87 \text{ kcal mol}^{-1}$.¹² Entropy based on geometric properties optimized at the MP2/6-31G(d') level and vibrational frequencies at the HF/6-31G(d') level.¹²

CH₃COO Vibrational frequencies calculated at the HF/6-31G(D) level and total energies evaluated at the G2(MP2) level, also making use of isodesmic reactions.¹⁴

CH₂(OH)CO and CH(OH)C(O)H

Enthalpy derived from isodesmic reactions calculated by the B3LYP/6-31G(d,p) and G3 methods. Reported results were adjusted for enthalpy values of reference compounds in this Table.³

CH₂(OH)C(O)H, glycoaldehyde

Enthalpy derived from isodesmic reactions calculated by the B3LYP/6-31G(d,p) and G3 methods. Reported results were adjusted for enthalpy values of reference compounds in this Table.³

CH₂C(O)OH

Enthalpy based on CID studies of the acetate radical anion yielding D(H-CH₂COOH) = $95.3 \pm 2.9 \text{ kcal mol}^{-1}$.¹³ Entropy based on vibrational frequencies calculated at the HF/6-31G(D) level.¹⁴ Isodesmic reactions at the G2(MP2) level give -243 kJ mol^{-1} .

CH₃C(O)O

Derived from a hybrid experimental/CBS-Q approach.⁷

CH₃C(O)OH, acetic acid

Enthalpy from Pedley⁸, entropy from Chao.¹

CH₂C(OH)₂, ethene, 1-diol

Enthalpy obtained from three isodesmic reactions at the G3MP2//B3LYP/6-31G(d) level of theory.¹⁰

CH₂(OH)CH₂OH, 1,2-ethanediol

Enthalpy from Pedley,⁸ entropy from Frenkel et al.⁴

C(OH)₂C(O)H, radical from ethanal, 2-diol

Calculated from two isodesmic reactions at the G3MP2//B3LYP/6-31G(d) level of theory.¹⁰

CH(OH)₂C(O)H, ethanal, 2-diol

Calculated from two isodesmic reactions at the G3MP2//B3LYP/6-31G(d) level of theory.¹⁰

C(O)HC(O)H, ethanedial (glyoxal)

From the review of Pedley.⁸

CH₂OOCH₃

Calculated using the complete basis set method, CBS-Q. Enthalpies calculated using the atomization energy method. Entropy based on geometric properties optimized at the MP2/6-

31G(d') level and vibrational frequencies at the HF/6-31G(d') level.¹² This radical is unstable towards decomposition.

CH₃OOCH₃

Enthalpy from updated JANAF Tables, based on calorimetric measurements.² Enthalpy calculated using the atomization energy method at the CBS-Q level gave $\Delta_f H_{298}^\circ = -29.17$ kcal mol⁻¹.¹² Entropy based on geometric properties optimized at the MP2/6-31G(d') level and vibrational frequencies at the HF/6-31G(d') level.¹²

Note 14: Alkylcarbonate radicals

[Back to Table](#)

Alkylcarbonate radicals

Formation enthalpies for these short-lived radicals were studied by the CBS-Q method, with geometry optimization at the MP2/6-31G(d) level. Enthalpies from both atomization and bond-separation reactions were calculated. The differences were 4 kJ mol⁻¹ or less, so the values were averaged for inclusion in the Table. The decomposition of the radicals was investigated by charge-reversal and neutralization-reionization mass spectrometry. For these ROC(O)O radicals, hydrogen-atom migration was important for R = CH₃ and C₂H₅, whereas decarboxylation was more important for R = H, *i*-C₃H₇, and *t*-C₄H₉.¹

Note 15: *Compounds with two C and more than 2 O*

[Back to Table](#)

CH₃C(O)O₂

Derived from a hybrid experimental/CBS-Q approach.³

CH₂(OH)C(O)OH, glycolic acid

From the updated JANAF Tables, estimated based on additivity methods.²

CH₂(OH)OOCH₂OH, dioxybismethanol

Taken from the review of Pedley⁴

(HOCO)₂, oxalic acid

Updated JANAF Tables, based on the enthalpy of combustion of the solid and the enthalpy of vaporization.²

CH₃O₄CH₃, dimethyl tetroxide

Molecular geometry optimized at the B3LYP/cc-pVTZ+d level of theory. The enthalpy was determined using G3B3 and CBS-APNO methods with isodesmic reactions to minimize systematic errors. Several bond dissociation energies were also reported.¹

C(OH)₂C(O)H, radical from ethanal, 2-diol

Calculated from two isodesmic reactions at the G3MP2//B3LYP/6-31G(d) level of theory.⁵

CH(OH)₂C(O)H, ethanal, 2-diol

Calculated from two isodesmic reactions at the G3MP2//B3LYP/6-31G(d) level of theory.⁵

Note 16: *Compounds with two C, one N, and 0-5 O*

[Back to Table](#)

C₂H₅NO₂

Calculated using G3, CBS-QB3, and CBS-APNO methods applied to atomization, isomerization, and work reactions. Value reported is $\Delta_f H_{298}^\circ = -25.06 \pm 0.07$ kcal mol⁻¹, which is adjusted using the reference enthalpy for *cis*-HONO from this Table.¹ A calculation of the atomization energy at the G3 level of theory leads to $\Delta_f H_{298}^\circ = -24.7$ kcal mol⁻¹. Calculations also carried out at the G2, G2M(CC5), B3LYP, MW1B95, and MPWB1K levels.⁴

C₂H₅ONO

Calculated using G3, CBS-QB3, and CBS-APNO methods applied to atomization, isomerization, and work reactions. Value reported is $\Delta_f H_{298}^\circ = -23.58 \pm 0.12$ kcal mol⁻¹, which is adjusted using the reference enthalpy for *cis*-HONO from this Table.¹ A calculation of the atomization energy at the G3 level of theory leads to $\Delta_f H_{298}^\circ = -22.9$ kcal mol⁻¹. Calculations also carried out at the G2, G2M(CC5), B3LYP, MW1B95, and MPWB1K levels.⁴

C₂H₅O₂NO₂

Equilibrium structures optimized at the MP2 level with the 6-311G(d,p) basis set and enthalpy values calculated by both atomization energies and through use of isodesmic reactions at the G3, G3B3, and G4 methods.³

CH₃C(O)O₂NO₂

Derived from a hybrid experimental/CBS-Q approach.⁵

CH₃CHN(O)OH

Enthalpy value calculated from the atomization energy at the G3 level of theory. Calculations also carried out at the G2, G2M(CC5), B3LYP, MW1B95, and MPWB1K levels.⁴

C₂H₅NH₂, ethylamine

From the review of Pedley.⁶ Values of $\Delta_f H_{298}^\circ = -50.1 \pm 1.5$ kJ mol⁻¹ and $\Delta_f H_0^\circ = -28.6 \pm 1.5$ kJ mol⁻¹ have been derived from a threshold PEPICO study of alkyl amines and the use of two isodesmic reaction networks, connected through the TPEPICO dissociation energies, and with reaction heats calculated at the CBS-APNO and W1U levels of theory.²

CH₃NHCH₃, dimethylamine

From the review of Pedley.⁶

CH₃CONH₂, acetamide

From the review of Pedley.⁶

Note 17: C₃ hydrocarbons

[Back to Table](#)

C₃H₄, propadiene

Enthalpy from Pedley.⁴

C₃H₄, propyne

Enthalpy from Pedley.⁴

cy-C₃H₃, 3-cyclopropenyl radical

The 3-cyclopropenium cation was reacted with a series of reagents to establish the ionization energy of the radical as 6.00±0.17 eV or 578.9±16.4 kJ mol⁻¹.⁹ This, combined with the enthalpy of formation of the reaction of 1076.5±3.3 kJ mol⁻¹, leads to the reported value. High level G3 and W1 calculation lead to similar values.

cy-C₃H₄, cyclopropene

Enthalpy from Pedley.⁴

C₃H₅

From a second-law analysis of C₃H₅ + HBr ↔ C₃H₆ + Br.⁶ A calculation at the HEAT345-Q level of theory gives recommended values of $\Delta_f H_0^\circ = 180.3 \pm 1.8$ kJ mol⁻¹ and $\Delta_f H_{298}^\circ = 168.6 \pm 1.8$ kJ mol⁻¹.⁸ This enthalpy difference provides the 0 K value in the Table.

- C₃H₆** Enthalpy from Pedley⁴, entropy from Chao.³
- n-C₃H₇** Enthalpy derived from a threshold PEPICO study of alkyl amines and the use of two isodesmic reaction networks, connected through the TPEPICO dissociation energies, and with reaction heats calculated at the CBS-APNO and W1U levels of theory.¹ Previous value of $\Delta_f H_{298}^\circ = 100 \pm 2$ kJ mol⁻¹ estimated by Tsang.¹⁰
- i-C₃H₇** From a second-law analysis of $\text{iso-C}_3\text{H}_7 + \text{HBr} \leftrightarrow \text{iso-C}_3\text{H}_8 + \text{Br}$.⁷ An enthalpy of $\Delta_f H_{298}^\circ = 88.5 \pm 1.0$ kJ mol⁻¹ and $\Delta_f H_0^\circ = 106.2 \pm 1.0$ kJ mol⁻¹ has been derived from a threshold PEPICO study of alkyl amines and the use of two isodesmic reaction networks, connected through the TPEPICO dissociation energies, and with reaction heats calculated at the CBS-APNO and W1U levels of theory.¹

Note 18: Compounds containing 3 C 1-8 H, and 1 O

[Back to Table](#)

1 and 2-C₃H₇OH

From review of Pedely et al.¹⁰

C₂H₅CO CBS-4 and G2(MP2,SVP) methods used to obtain thermodynamic properties. Value listed is recommendation based on theoretical and experimental results. Entropy at the G2(MP2(full))/MP2(full)/6-31G(d) level treating internal rotations as harmonic oscillators.¹⁴

C₂H₅C(O)H

Enthalpy from Pedley,¹⁰ entropy from Frenkel et al.⁵

CH₂CHOCH₃ and C₃H₅O

Methyl vinyl ether and corresponding radicals. Molecular geometry optimized at the B3LYP/6-31G(d,p) level of theory. The enthalpy was determined using CBS-Q, CBS-APNO,

and G3 methods with isodesmic reactions to minimize systematic errors. Entropies calculated by using the SMCPS program.²

CH₃C(O)CH₂

Enthalpy value an average of the a value obtained from the gas-phase basicity and proton affinity determined by a kinetic method (-34.6 ± 8.4 kJ mol⁻¹) and a reexamination of the results of Holmes et al.⁷ on the dissociation of 2-propenyl acetate and acetylacetone after electron ionization (-33.1 and -30.3 kJ mol⁻¹).¹ This value is supported by several computational studies.^{3,6,8} The previous recommendation, -28.1 ± 3.1 kJ mol⁻¹, was derived from forward and reverse rate constants for the reaction $\text{CH}_3\text{C}(\text{O})\text{CH}_2 + \text{HBr} \leftrightarrow \text{CH}_3\text{C}(\text{O})\text{CH}_3 + \text{Br}$.⁴ The reverse rate constant requires an extrapolation from high temperature for the reference reaction. An earlier photobromination determination of the reverse reaction results in an enthalpy value of -24.3 ± 5.8 kJ mol⁻¹.⁹ Density functional and ab initio calculations at the CBS-QB3 level of theory, using a series of isodesmic reactions, led to $\Delta_f H_{298}^\circ = -24.3 \pm 5.8$ kJ mol⁻¹.³ The entropy value is from G3MP2B3 calculation.⁸

CH₃C(O)CH₃

Enthalpy from review of Pedley;¹⁰ entropy value from Frenkel.⁵

CH₃CHOCH₃ and CH₃CH₂OCH₂

Calculated using the complete basis set method, CBS-Q. Enthalpies calculated using the atomization energy method. Entropy based on geometric properties optimized at the MP2/6-31G(d') level and vibrational frequencies at the HF/6-31G(d') level.¹³

CH₃CH₂OCH₃, methoxyethane (methyl ethyl ether)

Enthalpy from Pedley et al.¹⁰ Enthalpy calculated using the atomization energy method at the CBS-Q level gave -52.20 kcal mol⁻¹.¹³ Entropy based on geometric properties optimized at the MP2/6-31G(d') level and vibrational frequencies at the HF/6-31G(d') level.¹³

CH₂CC(O)H, radical from propenal

Enthalpy obtained from four isodesmic reactions at the G3MP2//B3LYP/6-31G(d) level of theory.¹¹

CH₂CHCO, radical from propenal

CBS-4 and G2(MP2,SVP) methods used to obtain thermodynamic properties. Value listed is recommendation based on theoretical and experimental results. Entropy at the G2(MP2(full)//MP2(full)/6-31G(d) level treating internal rotations as harmonic oscillators.¹⁴

CH₃CHCO, methyl ketene

Reaction enthalpies for two isodesmic reactions were calculated at the CBS-QB3, CBS-APNO, and G3 levels.¹² Preferred values for the reference compounds from this Table were employed.

CH₂CHC(O)H, propenal

Enthalpy obtained from two isodesmic reactions at the G3MP2//B3LYP/6-31G(d) level of theory.¹¹

Note 19: *Compounds containing 3 C 1-8 H, and 2 O*

[Back to Table](#)

C₃H₅O₂ Equilibrium constants for the reaction C₃H₅ + O₂ ⇌ C₃H₅O₂ were determined over the temperature range 320–420 K and fit to a van't Hoff plot. Combining the results with previous results led to Δ_rH₂₉₈[°] = -75.6 ± 2.3 kJ mol⁻¹ and Δ_rS = -129.9 ± 3.1 J K⁻¹mol⁻¹.⁵

CH₂CHOOCH₃

Thermodynamic parameters were determined at the B3LYP/6-311G(d,p) level of theory, with the enthalpy the average of 4-6 isodesmic reactions. The standard deviation of the enthalpy from the average of the isodesmic reactions was ±2.8 kJ mol⁻¹, but the estimated error limits for the individual isodesmic reactions, which take into account the uncertainty in each reactant and an estimated uncertainty due to thermal energy of 0.46 kJ mol⁻¹, ranged from ±6.7 to 14 kJ mol⁻¹.⁶

CH₃CH(OH)CH₂OH, 1,2-propanediol

From review of Pedley et al.⁴

C₃H₅OOH Enthalpy based on calculations made using the CBS-QB3 and CBS-APNO model chemistries on two isodesmic reactions.⁸

CH₂OC(O)CH₃ and CH₃OC(O)CH₃

Calculated using the complete basis set method, CBS-Q. Enthalpies calculated using the atomization energy method. Entropy based on geometric properties optimized at the MP2/6-31G(d⁺) level and vibrational frequencies at the HF/6-31G(d⁺) level.⁹

CH₃OCH₂OCH₃, dimethoxymethane

From the review of Pedley et al.⁴

CH₃CH₂OC(O), CH₃CHOC(O)H, CH₃CH₂OC(O)H

Calculated using the complete basis set method, CBS-Q. Enthalpies calculated using the atomization energy method. Entropy based on geometric properties optimized at the MP2/6-31G(d') level and vibrational frequencies at the HF/6-31G(d') level.⁹

CH₂(OH)C(O)CH₃, hydroxyacetone

Enthalpy derived from isodesmic reactions calculated by the B3LYP/6-31G(d,p) and G3 methods. Reported results were adjusted for enthalpy values of reference compounds in this Table.¹

CH₃CHOOCH₃

Calculated using the complete basis set method, CBS-Q. Enthalpies calculated using the atomization energy method. Entropy based on geometric properties optimized at the MP2/6-31G(d') level and vibrational frequencies at the HF/6-31G(d') level.⁹ This radical is unstable towards dissociation

CH₃CH₂OOCH₃

Calculated using the complete basis set method, CBS-Q. Enthalpies calculated using the atomization energy method. Entropy based on geometric properties optimized at the MP2/6-31G(d') level and vibrational frequencies at the HF/6-31G(d') level.⁹

(CH₃)₂CHOO

Based on a re-analysis of previous equilibrium data on $R + O_2 \leftrightarrow RO_2$ from the same laboratory.²

(CH₃)₂COOH

Calculated using the complete basis set method, CBS-Q. Enthalpies calculated using the atomization energy method. Entropy based on geometric properties optimized at the MP2/6-31G(d') level and vibrational frequencies at the HF/6-31G(d') level.⁹

(CH₃)₂CHOOH

Reaction enthalpy for the reaction $(CH_3)_2CHOO + CH_3OOH \rightarrow (CH_3)_2CHOOH + CH_3OO$ calculated to be 0.6 kcal mol⁻¹ using the QCISD(T)/6-31G**//MP2/6-31G* method.³ Enthalpy calculated using the atomization energy method at the CBS-Q level gave -48.1 kcal mol⁻¹.⁹ Entropy based on geometric properties optimized at the MP2/6-31G(d') level and vibrational frequencies at the HF/6-31G(d') level.⁹

CH₃C(OH)₂C(O)OH

Enthalpy obtained from three isodesmic reactions at the G3MP2//B3LYP/6-31G(d) level of theory.⁷

CH₂(OH)CH(OH)CH₂OH, 1,2,3-propanetriol

Taken from the review of Pedley et al.⁴

CH₂CHOOCH₃

Thermodynamic parameters were determined at the B3LYP/6-311G(d,p) level of theory, with the enthalpy the average of 4-6 isodesmic reactions. The standard deviation of the enthalpy from the average of the isodesmic reactions was ± 2.8 kJ mol⁻¹, but the estimated error limits for the individual isodesmic reactions, which take into account the uncertainty in each reactant and an estimated uncertainty due to thermal energy of 0.46 kJ mol⁻¹, ranged from ± 6.7 to 14 kJ mol⁻¹.⁶

Note 20: Compounds containing 3 C, H, N, and O

[Back to Table](#)

$\text{C}_3\text{H}_7\text{NH}_2$ Enthalpy derived from a threshold PEPICO study of alkyl amines and the use of two isodesmic reaction networks, connected through the TPEPICO dissociation energies, and with reaction heats calculated at the CBS-APNO and W1U levels of theory.²

$(\text{CH}_3)_3\text{N}$, trimethylamine

From the review of Pedley et al.⁵

$(\text{CH}_3)_3\text{NO}$, trimethylene-*N*-oxide

Enthalpy from heat of combustion of solid and estimated sublimation enthalpy.¹

$\text{C}_3\text{H}_7\text{O}_2\text{NO}_2$

Equilibrium structures optimized at the MP2 level with the 6-311G(d,p) basis set and enthalpy values calculated by both atomization energies and through use of isodesmic reactions at the G3, G3B3, and G4 methods.³

NCC(O)CN, oxopropanedinitrile

From the updated JANAF Tables, based on calorimetric measurements.⁴

[Back to Table](#)

***n*- C_4H_{10}** Enthalpy by combustion calorimetry.⁷ Entropy by ideal gas properties calculations.⁴

$(\text{CH}_3)_2\text{CCO}$, dimethyl ketene

Reaction enthalpies for three isodesmic reactions were calculated at the CBS-QB3, CBS-APNO, and G3 levels.⁹ The preferred value for ketene from this Table was employed.

$(\text{CH}_3)_3\text{CO}$, *tert*-Butoxyl

Earlier photoacoustic calorimetry results were combined with redetermined values of the enthalpy of formation and vaporization of di-1,1-dimethylethyl peroxide (using combustion calorimetry, ebulliometry, and heat capacity measurements) to derive this improved enthalpy of formation.²

(CH₃)₃COO

Based on a re-analysis of previous equilibrium data on $R + O_2 \leftrightarrow RO_2$ from the same laboratory.⁵

(CH₃)₃COOH

Enthalpy based on the gas-phase acidity and electron affinity from a negative ion photoelectron spectral study, leading to a BDE(O-H) of 85 ± 2 kcal mol⁻¹ (83 ± 2 kcal mol⁻¹ at 0 K).¹ Reaction enthalpy for the reaction $(CH_3)_3COO + CH_3OOH \rightarrow (CH_3)_3COOH + CH_3OO$ was calculated to be 1.3 kcal mol⁻¹ using the QCISD(T)/6-31G**// MP2/6-31G* method, leading to $\Delta_f H_{298}^\circ = -56.8$ kcal mol⁻¹.⁶

(CH₃COO)₂, diacetyl peroxide

From updated JANAF Tables, based on a calorimetric measurement on the liquid and an assumed enthalpy of vaporization.³

trans-CH₃CHCHOOCH₃

Thermodynamic parameters were determined at the B3LYP/6-311G(d,p) level of theory, with the enthalpy the average of 4-6 isodesmic reactions. The standard deviation of the enthalpy from the average of the isodesmic reactions was ± 2.8 kJ mol⁻¹, but the estimated error limits for the individual isodesmic reactions, which take into account the uncertainty in each reactant and an estimated uncertainty due to thermal energy of 0.46 kJ mol⁻¹, ranged from ± 4.2 to 10.3 kJ mol⁻¹.⁸

cis-CH₃CHCHOOCH₃

Thermodynamic parameters were determined at the B3LYP/6-311G(d,p) level of theory, with the enthalpy the average of 4-6 isodesmic reactions. The standard deviation of the enthalpy from the average of the isodesmic reactions was ± 2.0 kJ mol⁻¹, but the estimated error limits for the individual isodesmic reactions, which take into account the uncertainty in each reactant and an estimated uncertainty due to thermal energy of 0.46 kJ mol⁻¹, ranged from ± 4.0 to 8.0 kJ mol⁻¹.⁸

CH₂C(CH₃)OOCH₃

Thermodynamic parameters were determined at the B3LYP/6-311G(d,p) level of theory, with the enthalpy the average of 4-6 isodesmic reactions. The standard deviation of the enthalpy from the average of the isodesmic reactions was ± 1.8 kJ mol⁻¹, but the estimated error limits for the individual isodesmic reactions, which take into account the uncertainty in each reactant and an estimated uncertainty due to thermal energy of 0.46 kJ mol⁻¹, ranged from ± 3.8 to 7.8 kJ mol⁻¹.⁸

CH₂CHCH₂OOCH₃

Thermodynamic parameters were determined at the B3LYP/6-311G(d,p) level of theory, with the enthalpy the average of 4-6 isodesmic reactions. The standard deviation of the enthalpy from the average of the isodesmic reactions was ± 1.1 kJ mol⁻¹, but the estimated error limits for the individual isodesmic reactions, which take into account the uncertainty in each reactant and an estimated uncertainty due to thermal energy of 0.46 kJ mol⁻¹, ranged from ± 3.2 to 7.4 kJ mol⁻¹.⁸

Note 22: Inorganic compounds containing F

[Back to Table](#)

- F** Enthalpy value is from the optimization in the Active Thermochemical Tables (ATcT).¹⁶ CODATA Key Value⁴ of $\Delta_f H_{298}^\circ = 79.38 \pm 0.30 \text{ kJ mol}^{-1}$ was used in previous evaluation. Entropy value is from CODATA.
- F₂** CODATA Key Value.⁴
- HF** CODATA Key Value.⁴ The active thermochemical tables optimization gives an enthalpy value of $-272.775 \pm 0.24 \text{ kJ mol}^{-1}$.¹⁷ The most recent NIST-JANAF review gives an enthalpy of $-273.3000 \pm 0.70 \text{ kJ mol}^{-1}$ and an entropy of $173.778 \pm 0.005 \text{ J K}^{-1} \text{ mol}^{-1}$.¹⁸ A network optimization of *ab initio* reaction enthalpies results in a value of $\Delta_f H_0^\circ = -272.82 \pm 0.35 \text{ kJ mol}^{-1}$.⁵ The uncertainty corresponds to the 95% confidence limit. The reference atomic values were taken from the Active Thermochemical Tables, ver. 1.20.
- HO_F** Enthalpy value at 0 K from a re-evaluation of the photoionization studies, along with the newer enthalpy for OH and a more recent ionization energy for OH.¹⁵ Previous values of $\Delta_f H_{298}^\circ = -98.3 \pm 4.2 \text{ kJ mol}^{-1}$ and $\Delta_f H_0^\circ = -95.4 \pm 4.2 \text{ kJ mol}^{-1}$ from JANAF review from 1972.³ A calculation of the isodesmic reaction $\text{HO}_F + \text{OH} \rightarrow \text{FO} + \text{H}_2\text{O}$ at the W4.2 level of theory leads to $\Delta_f H_{298}^\circ = -87.2 \pm 0.6 \text{ kJ mol}^{-1}$ and $\Delta_f H_0^\circ = -84.3 \pm 0.6 \text{ kJ mol}^{-1}$, in good agreement.¹³
- FO** Atomization energy was calculated using the Wn family of computational methods. Small increases in the atomization energy were found going from W2.2 to W4.4. These results led to $\Delta_f H_{298}^\circ = 110.58 \pm 0.46 \text{ kJ mol}^{-1}$ and $\Delta_f H_0^\circ = 109.96 \pm 0.46 \text{ kJ mol}^{-1}$.¹³ Atomization energy calculated at the CCSD(T)(FC) level through aug-cc-PV7Z basis sets led to $\Delta_f H_{298}^\circ = 110.88 \pm 0.84 \text{ kJ mol}^{-1}$ and $\Delta_f H_0^\circ = 110.04 \pm 0.84 \text{ kJ mol}^{-1}$.⁹ These were averaged to give the Table values. The previous table values of $\Delta_f H_{298}^\circ = 109 \pm 10 \text{ kJ mol}^{-1}$ and $\Delta_f H_0^\circ = 108 \pm 10 \text{ kJ mol}^{-1}$ were from the NIST-JANAF thermochemical tables for the oxygen fluorides² and were based on mass spectrometric and thermal decomposition studies of FOF. The atomization energy calculated with CCSD(T) using aug-cc-pVnZ (n=D-6) basis sets, approaching the complete basis set limit, resulted in $\Delta_f H_{298}^\circ = 27.9 \pm 0.4 \text{ kcal mol}^{-1}$ and $\Delta_f H_0^\circ = 27.6 \pm 0.4 \text{ kcal mol}^{-1}$.⁷ The entropy value is from JANAF.²
- FO_F** NIST-JANAF thermochemical tables for the oxygen fluorides.² Enthalpy based on a series of calorimetric studies. Atomization energy calculated at the CCSD(T)(FC) level through aug-cc-PV7Z basis sets led to $\Delta_f H_{298}^\circ = 24.7 \pm 1.3 \text{ kJ mol}^{-1}$ and $\Delta_f H_0^\circ = 26.8 \pm 1.3 \text{ kJ mol}^{-1}$.⁹ The atomization energy calculated with CCSD(T) using aug-cc-pVnZ (n=D-6) basis sets, approaching the complete basis set limit, resulted in $\Delta_f H_{298}^\circ = 6.6 \pm 0.5 \text{ kcal mol}^{-1}$ and $\Delta_f H_0^\circ =$

$7.1 \pm 0.5 \text{ kcal mol}^{-1}$.⁷ An extrapolation of a CCSD(T) calculation with aug-cc-pVTZ and aug-cc-pVQZ basis sets lead to $\Delta_f H_{298}^\circ = 24.4 \pm 4 \text{ kJ mol}^{-1}$.¹²

OFO Atomization energy calculated at the CCSD(T)(FC) level through aug-cc-PV7Z basis sets led to the listed enthalpy.⁹ The previous Table values of $\Delta_f H_{298}^\circ = 380 \pm 20 \text{ kJ mol}^{-1}$ and $\Delta_f H_0^\circ = 381 \pm 20 \text{ kJ mol}^{-1}$ were from the NIST-JANAF thermochemical tables for the oxygen fluorides and was based on a calculated value of enthalpy difference between OFO and FOO at 0 K of 356 kJ mol^{-1} .² The entropy value is also from the JANAF Table and is based on the earlier computational results.

FOO From an analysis of studies of the equilibrium $\text{F} + \text{O}_2 \leftrightarrow \text{FOO}$ (Table 3-1, Note 10). NIST-JANAF thermochemical tables for the oxygen fluorides, based on several experimental values, primarily from kinetic studies recommends $\Delta_f H_{298}^\circ = 25.4 \pm 2 \text{ kJ mol}^{-1}$ and $\Delta_f H_0^\circ = 27.2 \pm 2 \text{ kJ mol}^{-1}$.² This is also the source of the entropy value. A determination of the atomization energy gave $\Delta_f H_{298}^\circ = 5.8 \pm 0.3 \text{ kcal mol}^{-1}$,⁸ whereas a UCCSDT calculation led to $\Delta_f H_{298}^\circ = 6.5 \pm 1 \text{ kcal mol}^{-1}$.⁶ Atomization energy was calculated using the Wn family of computational methods. Significant increases in the atomization energy were found going from W2.2 to W4.4. These results led to $\Delta_f H_{298}^\circ = 24.6 \pm 0.7 \text{ kJ mol}^{-1}$ and $\Delta_f H_0^\circ = 26.4 \pm 0.7 \text{ kJ mol}^{-1}$.¹³ Atomization energy calculated at the CCSD(T)(FC) level through aug-cc-PV7Z basis sets led to $\Delta_f H_{298}^\circ = 26.8 \pm 2.9 \text{ kJ mol}^{-1}$ and $\Delta_f H_0^\circ = 28.9 \pm 2.9 \text{ kJ mol}^{-1}$.⁹

HOOF Atomization energy calculated by the CCSD(T) extrapolated to the CBS limit, with geometry optimized through the CCSD(T)/aV(T+d)Z level.¹⁰

FOOF NIST-JANAF thermochemical tables for the oxygen fluorides.² Value adopted for enthalpy is that recommended by Lyman¹⁴ based on a calorimetric measurement on the decomposition into O_2 and F_2 . The atomization energy calculated with CCSD(T) using aug-cc-pVnZ (n=D-6) basis sets, approaching the complete basis set limit, resulted in $\Delta_f H_{298}^\circ = 40.2 \pm 3.8 \text{ kJ mol}^{-1}$ and $\Delta_f H_0^\circ = 43.9 \pm 3.8 \text{ kJ mol}^{-1}$.⁷ Atomization energy was calculated using the Wn family of computational methods. Significant increases in the atomization energy were found going from W2.2 to W4.4. These results led to $\Delta_f H_{298}^\circ = 32.8 \pm 0.75 \text{ kJ mol}^{-1}$ and $\Delta_f H_0^\circ = 37.24 \pm 0.75 \text{ kJ mol}^{-1}$.¹³ Atomization energy calculated at the CCSD(T)(FC) level through aug-cc-PV7Z basis sets led to $\Delta_f H_{298}^\circ = 26.8 \pm 2.9 \text{ kJ mol}^{-1}$ and $\Delta_f H_0^\circ = 31.0 \pm 2.9 \text{ kJ mol}^{-1}$.⁹ An extrapolation of a CCSD(T) calculation with aug-cc-pVTZ and aug-cc-pVQZ basis sets lead to $\Delta_f H_{298}^\circ = 34.8 \pm 4 \text{ kJ mol}^{-1}$.¹²

FOOOF, for the C₂ conformer

Based on an extrapolation of a CCSD(T) calculation with aug-cc-pVTZ and aug-cc-pVQZ basis sets. For the C_s conformer, $\Delta_f H_{298}^\circ = 111.3 \pm 4 \text{ kJ mol}^{-1}$ and $S = 204.3 \text{ J K mol}^{-1} \text{ K}^{-1}$.¹²

FNO The equilibrium geometry was calculated at the CCSD(T)/cc-pVQZ level of theory, while the energy was calculated by summing various contributions calculated at the CCSC(T) level with the use of various basis sets.²⁰ The previous value, $\Delta_f H_{298}^\circ = -65.7 \text{ kJ mol}^{-1}$, was taken from review of Stull, et al.¹⁹ The JANAF Tables give $\Delta_f H_0^\circ = -63.3 \text{ kJ mol}^{-1}$, $\Delta_f H_{298}^\circ = -65.7 \text{ kJ mol}^{-1}$, and $S^\circ = 248.082 \text{ J mol}^{-1} \text{ K}^{-1}$.³

cis, trans-FONO

The equilibrium geometry was calculated at the CCSD(T)/cc-pVQZ level of theory, while the energy was calculated by summing various contributions calculated at the CCSC(T) level with the use of various basis sets.²⁰ The previous value, $\Delta_f H_{298}^\circ = 67 \text{ kJ mol}^{-1}$, was estimated.¹

FNO₂ The equilibrium geometry was calculated at the CCSD(T)/cc-pVQZ level of theory, while the energy was calculated by summing various contributions calculated at the CCSC(T) level with the use of various basis sets.²⁰ The previous value, $\Delta_f H_{298}^\circ = -79 \text{ kJ mol}^{-1}$, was taken from review of Stull et al.¹⁹

- FONO₂** The equilibrium geometry was calculated at the CCSD(T)/cc-pVQZ level of theory, while the energy was calculated by summing various contributions calculated at the CCSC(T) level with the use of various basis sets.²⁰ The previous value, $\Delta_f H_{298}^\circ = 15 \pm 3 \text{ kJ mol}^{-1}$, was taken from review of Gurvich et al.¹¹ The JANAF estimate from 1963 gave an enthalpy of $10 \pm 2 \text{ kJ mol}^{-1}$.³
- NF₂** Enthalpy value from a reanalysis of the data used by JANAF, combined with the newer enthalpy value for NF₃.²¹
- NF₃** A study of the combustion of rhombic sulfur in NF₃ to generate SF₆ and N₂ using $\Delta_f H_{298}^\circ(\text{SF}_6) = -1220.8 \pm 0.8 \text{ kJ mol}^{-1}$ results in the enthalpy of NF₃.²¹

- CF** Thermodynamic properties from Gurvich et al. review.⁵ A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to $\Delta_f H_0^\circ = 243.3 \pm 0.8$ kJ mol⁻¹, $\Delta_f H_{298}^\circ = 247.0 \pm 0.8$ kJ mol⁻¹, and $S = 212.9 \pm 1.5$ J K⁻¹ mol⁻¹.⁴
- CHF** Calculated for the X¹A' state. Enthalpy from a CCSD(T) calculation with the aug-cc-pVnZ (n=D,T,Q,5) basis set extrapolated to the CBS limit and entropy from a MP2/aVTZ calculation.⁸ Enthalpy obtained using the computed enthalpy of a reaction of the type: CH₂(¹A₁) + CH₂F₂ + 2CH₃Y → CFY(¹A₁) + 3CH₄ results in $\Delta_f H_{298}^\circ = 146$ kJ mol⁻¹ at the QCISD(T)/6-311+G(3df,2p)//QCISD/6-311G(d,p) level of theory. Calculations also done at the G2 level.¹⁴ Previous recommendation, $\Delta_f H_{298}^\circ = 143 \pm 13.0$ kJ mol⁻¹, based on combining experimental chloride dissociation energies from the parent anion, prior experimental measurements, and G2 calculations.¹¹ A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to $\Delta_f H_0^\circ = 148.9 \pm 1.2$ kJ mol⁻¹, $\Delta_f H_{298}^\circ = 149.0 \pm 1.2$ kJ mol⁻¹, and $S = 223.1 \pm 1.5$ J K⁻¹ mol⁻¹.⁴
- CH₂F** Derived from the kinetics and equilibria of the iodination reaction CH₃F + I₂ ↔ CH₂FI + HI.¹⁰ A QCISD(T)/6-311+G(3df,2p) isodesmic study resulted in an enthalpy of -29.0 ± 4.1 kJ mol⁻¹.¹⁵ A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to $\Delta_f H_0^\circ = -27.9 \pm 1.6$ kJ mol⁻¹, $\Delta_f H_{298}^\circ = -31.2 \pm 1.6$ kJ mol⁻¹, and $S = 232.5 \pm 1.5$ J K⁻¹ mol⁻¹.⁴ This enthalpy difference was used to calculate the 0 K value in the Table.
- CH₃F** Enthalpies of reaction calculated (and averaged) at the MCG3/MCQCISD level of theory (up to 6-311++G(3d2f,2df,2p) basis set) for the homolytic fragmentation to the alkyl radical and fluoride atom, and for the atomization reaction. Enthalpy also calculated for the heterolytic fragmentation into the alkyl cation and fluoride anion for support.⁶ Previous value, $\Delta_f H_{298}^\circ = -238 \pm 8$ kJ mol⁻¹, estimated in review of Rodgers et al.¹² Luo and Benson recommend -55.9 ± 1 kcal/mol.⁷ A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to $\Delta_f H_0^\circ = -228.5 \pm 2.0$ kJ mol⁻¹, $\Delta_f H_{298}^\circ = -236.9 \pm 2.0$ kJ mol⁻¹, and $S = 222.5 \pm 1.5$ J K⁻¹ mol⁻¹.⁴ This enthalpy difference was used to calculate the 0 K value in the Table.
- CF₂** Calculated for the X¹A' state. Enthalpy from a CCSD(T) calculation with the aug-cc-pVnZ (n=D,T,Q,5) basis set extrapolated to the CBS limit and entropy from a MP2/aVTZ calculation.⁸ $\Delta_f H_0^\circ = -46.0 \pm 0.8$ kcal mol⁻¹. Enthalpy obtained using the computed enthalpy of a reaction of the type: CH₂(¹A₁) + CH₂F₂ + 2CH₃Y → CFY(¹A₁) + 3CH₄ results in $\Delta_f H_{298}^\circ = -196$ kJ mol⁻¹ at the QCISD(T)/6-311+G(3df,2p)//QCISD/6-311G(d,p) level of theory. Calculations also done at the G2 level.¹⁴ Previous recommendation, -44.0 ± 2 kcal mol⁻¹, based

on combining experimental chloride dissociation energies from the parent anion, prior experimental measurements, and G2 calculations.¹¹ A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to $\Delta_f H_0^\circ = -193.6 \pm 1.2$ kJ mol⁻¹, $\Delta_f H_{298}^\circ = -193.2 \pm 1.2$ kJ mol⁻¹, and $S = 240.6 \pm 1.5$ J K⁻¹ mol⁻¹.⁴

- CHF₂** Derived from the kinetics and equilibria of the iodination reaction $\text{CH}_3\text{F} + \text{I}_2 \leftrightarrow \text{CH}_2\text{FI} + \text{HI}$.¹⁰ A QCISD(T)/6-311+G(3df,2p) isodesmic study resulted in an enthalpy of -241.2 ± 4.1 kJ mol⁻¹.¹⁵ A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to $\Delta_f H_0^\circ = -239.4 \pm 2.6$ kJ mol⁻¹, $\Delta_f H_{298}^\circ = -243.0 \pm 2.6$ kJ mol⁻¹, and $S = 255.8 \pm 6.5$ J K⁻¹ mol⁻¹.⁴ The enthalpy difference was used to calculate the 0 K value in the Table.
- CH₂F₂** From review by Rodgers et al.¹² Pedley gives -452.3 ± 0.9 kJ mol⁻¹.⁹ A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to $\Delta_f H_0^\circ = -442.6 \pm 2.0$ kJ mol⁻¹, $\Delta_f H_{298}^\circ = -450.5 \pm 2.0$ kJ mol⁻¹, and $S = 246.3 \pm 1.5$ J K⁻¹ mol⁻¹.⁴ The enthalpy difference was used to calculate the 0 K value in the Table.
- CF₃** Enthalpy from a simultaneous solution of a thermochemical network for the CF₃X species, where X = nil, H, Cl, Br, I, CF₃, CN.¹³ Entropy from recommendation of Gurvich et al.⁵ A QCISD(T)/6-311+G(3df,2p) isodesmic study resulted in an enthalpy of -465.9 ± 4.1 kJ mol⁻¹.¹⁵ A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to $\Delta_f H_0^\circ = -464.8 \pm 1.6$ kJ mol⁻¹, $\Delta_f H_{298}^\circ = -467.6 \pm 1.6$ kJ mol⁻¹, and $S = 264.1 \pm 1.5$ J K⁻¹ mol⁻¹.⁴
- CHF₃** Enthalpy from a simultaneous solution of a thermochemical network for the CF₃X species, where X = nil, H, Cl, Br, I, CF₃, CN.¹³ Entropy from recommendation of Gurvich et al.⁵ An enthalpy calculation from the atomization energy was obtained starting with a 'best estimated' structure from extensive calculations and analysis, followed by CCST with aug-cc-pVQZ and aug-cc-pV5Z basis sets, and CCSD(T) with aug-cc-pVTZ and aug-cc-pVQZ basis sets. Values of $\Delta_f H_0^\circ = -165.18$ kcal mol⁻¹ and $\Delta_f H_{298}^\circ = -166.86$ kcal mol⁻¹ were obtained.¹ A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to $\Delta_f H_0^\circ = -687.7 \pm 2.0$ kJ mol⁻¹, $\Delta_f H_{298}^\circ = -694.9 \pm 2.0$ kJ mol⁻¹, and $S = 259.2 \pm 1.5$ J K⁻¹ mol⁻¹.⁴
- CF₄** CODATA Key Value.³ The JANAF Tables give $\Delta_f H_0^\circ = -927.2$ kJ mol⁻¹, $\Delta_f H_{298}^\circ = -933.2$ kJ mol⁻¹, and $S^\circ = 261.419$ J mol⁻¹.² A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to $\Delta_f H_0^\circ = -927.8 \pm 2.0$ kJ mol⁻¹, $\Delta_f H_{298}^\circ = -933.8 \pm 2.0$ kJ mol⁻¹, and $S = 260.9 \pm 1.5$ J K⁻¹ mol⁻¹.⁴

Note 24: Compounds containing one C and one or more F and O

[Back to Table](#)

CFH₂O and CFH₂OH

The enthalpies of formation are based on isodesmic reactions calculated at the MP2/6-31G(d,p) level of theory.¹⁶

FCO

The enthalpy values are taken from a CCSDT(Q) calculation, with structure optimized using the cc-pVQZ basis set.¹⁴ The previous $\Delta_f H_{298}^\circ = -174.1 \pm 2$ was from a CCSD(T) calculation with the aug-cc-pVnZ (n=D,T,Q,5) basis set extrapolated to the CBS limit.¹³ The entropy value is from a MP2/aVTZ calculation.¹³ The decomposition rate constant for $\text{FCO} \rightarrow \text{F} + \text{CO}$,⁹ combined with the rate constant $k = 2.4 \times 10^{-22} \text{ cm}^6 \text{ s}^{-1}$ ¹⁸ for the reverse reaction, results in an upper limit of $\Delta_f H_{298}^\circ < -153.1 \text{ kJ mol}^{-1}$.⁹ A CCSD(T) calculation gives $\Delta_f H_{298}^\circ = -42.0 \pm 0.5 \text{ kcal mol}^{-1}$.⁴

FCO₂, fluoroformyl radical

Calculated at the CCSD(T) level of theory. CFO value from same work is $-42.0 \pm 0.5 \text{ kcal mol}^{-1}$, which differs from value in Table.⁴

CHFO

The enthalpy values are taken from a CCSDT(Q) calculation, with structure optimized using the cc-pVQZ basis set.¹⁴ The previous $\Delta_f H_{298}^\circ = -381.2 \pm 2$ was from a CCSD(T) calculation with the aug-cc-pVnZ (n = D,T,Q,5) basis set extrapolated to the CBS limit.¹³ The entropy value is from a MP2/aVTZ calculation.¹³ The earlier enthalpy value, $-91.6 \text{ kcal mol}^{-1}$, was from an G2(MP2) calculation,¹⁷ and the earlier entropy was from Gurvich et al.⁸

CF₂HFO and CF₂HOH

The enthalpies of formation are based on isodesmic reactions calculated at the MP2/6-31G(d,p) level of theory.¹⁶

CF₂O

The enthalpy values are taken from a CCSDT(Q) calculation, with structure optimized using the cc-pVQZ basis set,¹⁴ supported by several earlier computational studies discussed in that paper.^{3,7,13} The previous $\Delta_f H_{298}^\circ = -623.8 \pm 5.9$ was a lower limit from a photoionization study.¹ Entropy from Gurvich et al.⁸ Pedley review gives an enthalpy value of $-639.8 \pm 1.4 \text{ kJ}$

mol⁻¹.¹⁵ A CCSD(T) calculation with the aug-cc-pVnZ (n=D,T,Q,5) basis set extrapolated to the CBS limit gave $\Delta_f H_0^\circ = -143.9 \pm 0.5$ kcal mol⁻¹, $\Delta_f H_{298}^\circ = -144.7 \pm 0.5$ kcal mol⁻¹, and $S = 61.87$ cal K⁻¹mol⁻¹.¹³

- CF₃O** Re-analysis of data of Batt and Walsh, using new value for CF₂O.¹ The enthalpy of formation, $\Delta_f H_{298}^\circ = -154.5$ kcal mol⁻¹ based on an isodesmic reaction calculated at the MP2/6-31G(d,p) level of theory.¹⁶
- CF₂O₂** Determined on the basis of extensive ab initio calculations.¹¹ Isomeric forms F₂COO and FC(=O)OF are calculated to have enthalpies of -60 and -104 kcal mole⁻¹, respectively.
- CF₃O₂** Two values for the C-O bond dissociation energy in CF₃O₂ are given in Lightfoot, et al., -144±3.3 and -141±10 kJ mol⁻¹ at 0 K and adjusted to 298 K.¹² The value given is an average of the two resulting enthalpies.
- CF₃OH** Proton affinity obtained by using transitional energy threshold measurements on protonated trifluoromethanol. This was used in a thermochemical cycle to derive the enthalpy of formation.⁶ Previous value was based on a photoionization study, where a lower limit of $\Delta_f H_{298}^\circ > -908.8 \pm 0.9$ kJ mol⁻¹ was presented.² The enthalpy of formation, $\Delta_f H_{298}^\circ = -933.4$ kJ mol⁻¹, based on an isodesmic reaction calculated at the MP2/6-31G(d,p) level of theory.¹⁶
- CF₃OF** Based on photoionization of CF₃OF and an analysis of the CF₃⁺ and CF₂O⁺ fragments.² A G2 calculation led to an enthalpy of -774.5 kJ mol⁻¹.⁵

CH₂FOOH, CHF₂OOH, and CF₃OOH

Geometry optimization and frequency calculations were performed at the MP2/6-31G(d) and the B3LYP/6-311++G(d,p) levels of theory, with a single-point energy calculation at the CCSD(T)/6-311++G(d,p)/B3LYP/6-311++G(d,p) level. The dissociation energy into HO₂ and the alkyl radical was then evaluated and used, after thermal correction, to calculate the enthalpy of formation at 298 K.¹⁰ This was adjusted to the radical values from the present Table.

CH₂CHF Enthalpy from review of Pedley.¹³

CH₂CH₂F and CH₃CHF

Enthalpy from photobromination studies.¹¹ Entropy determined at the UHF/6-31G* level of theory.²

CH₃CH₂F Conformers and rotational barriers determined at the CCSD(T)/cc-pVTZ level of theory and the resulting equilibrium structure optimized at the CCSD(T)/cc-pVQZ level. The total electronic energy was calculated at the complete basis set limit (extrapolated from aug-cc-pVXZ (X = T, Q, 5)) energies, corrected for correlation contributions, the core correlation, the zero-point energy, diagonal Born-Oppenheimer contributions, and the scalar relativistic effect. The heat of formation was computed from the calculated enthalpies by using the elemental reaction approach, taking the gaseous atom as the standard state for carbon.¹² Previous value of $\Delta_f H_{298}^\circ = -278.2 \pm 1.7$ kJ mol⁻¹ was based on enthalpies of reaction calculated at the MCG3/MCQCISD level of theory (up to 6-311++G(3d2f,2df,2p) basis set) for the homolytic fragmentation to the alkyl radical and fluoride atom, and for the atomization reaction and

averaged. Enthalpy also calculated for the heterolytic fragmentation into the alkyl cation and fluoride anion for support.⁸ Previous entropy $S^\circ = 265.1 \text{ J mol}^{-1}$ from Gurvich et al. review.⁶

CH₂CF₂ Enthalpy from review of Pedley.¹³

CH₃CHF₂, 1,1-difluoroethane

Conformers and rotational barriers determined at the CCSD(T)/cc-pVTZ level of theory and the resulting equilibrium structure optimized at the CCSD(T)/cc-pVQZ level. The total electronic energy was calculated at the complete basis set limit (extrapolated from aug-cc-pVXZ (X = T, Q, 5)) energies, corrected for correlation contributions, the core correlation, the zero-point energy, diagonal Born-Oppenheimer contributions, and the scalar relativistic effect. The heat of formation was computed from the calculated enthalpies by using the elemental reaction approach, taking the gaseous atom as the standard state for carbon.¹² Previous value of $\Delta_f H_{298}^\circ = -497.0 \pm 8.3 \text{ kJ mol}^{-1}$ was from a review by Pedley.¹³

anti- and gauche-CH₂FCH₂F, 1,2-difluoroethanes

The conformationally averaged values are $\Delta_f H_{298}^\circ = -446.9 \pm 3.4 \text{ kJ mol}^{-1}$ and $S^\circ = 296.8 \pm 2.8 \text{ J mol}^{-1}$. Conformers and rotational barriers determined at the CCSD(T)/cc-pVTZ level of theory and the resulting equilibrium structure optimized at the CCSD(T)/cc-pVQZ level. The total electronic energy was calculated at the complete basis set limit (extrapolated from aug-cc-pVXZ (X = T, Q, 5)) energies, corrected for correlation contributions, the core correlation, the zero-point energy, diagonal Born-Oppenheimer contributions, and the scalar relativistic effect. The heat of formation was computed from the calculated enthalpies by using the elemental reaction approach, taking the gaseous atom as the standard state for carbon.¹² Previous enthalpy of $\Delta_f H_{298}^\circ = -232 \pm 25 \text{ kJ mol}^{-1}$ was based on an analysis of the thermal elimination of HF from CH₂FCH₂F, which led to a C-C bond dissociation energy of $88 \pm 2 \text{ kcal mol}^{-1}$.⁷

CH₂FCHF Thermodynamic properties determined at the UHF/6-31G* level, utilizing isodesmic/homodesmic reactions for enthalpy of formation.⁴

CHF₂CH₂ Thermodynamic properties determined at the UHF/6-31G* level, utilizing isodesmic/homodesmic reactions for enthalpy of formation.²

CH₃CF₂ The dissociation energy of CH₃CF₂-H of $99.5 \pm 1 \text{ kcal mol}^{-1}$ was derived from a study of the equilibrium $\text{CH}_3\text{CF}_2\text{H} + \text{I}_2 \leftrightarrow \text{CH}_3\text{CF}_2\text{I} + \text{HI}$.¹⁴ Entropy calculated from molecular properties computed at the UHF/6-31* level of theory.³

CH₃CHF₂ Taken from a Thermodynamics Research Center review.¹

anti- and gauche-CH₂FCHF₂, 1,1,2-trifluoroethanes

The conformationally averaged values are, $\Delta_f H_{298}^\circ = -661 \pm 3.4 \text{ kJ mol}^{-1}$ and $S^\circ = 316.9 \pm 2.0 \text{ J mol}^{-1}$. Conformers and rotational barriers determined at the CCSD(T)/cc-pVTZ level of theory and the resulting equilibrium structure optimized at the CCSD(T)/cc-pVQZ level. The total electronic energy was calculated at the complete basis set limit (extrapolated from aug-cc-pVXZ (X = T, Q, 5)) energies, corrected for correlation contributions, the core correlation, the zero-point energy, diagonal Born-Oppenheimer contributions, and the scalar relativistic effect. The heat of formation was computed from the calculated enthalpies by using the elemental reaction approach, taking the gaseous atom as the standard state for carbon.¹² Previous value of $\Delta_f H_{298}^\circ = -665 \pm 4 \text{ kJ mol}^{-1}$ was based on the heat of hydrogenation of CF₂CFCl.⁹ Pedley gives an enthalpy value of $-730.7 \pm 20.8 \text{ kJ mol}^{-1}$.¹³

CH₂CF₃ The dissociation energy of CF₃CH₂-H was derived from a study of the equilibrium $\text{CF}_3\text{CH}_3 + \text{I}_2 \leftrightarrow \text{CF}_3\text{CH}_2\text{I} + \text{HI}$.¹⁶ Entropy calculated from molecular properties computed at the UHF/6-31* level of theory.²

CH₃CF₃, 1,1,1-trifluoroethane

Conformers and rotational barriers determined at the CCSD(T)/cc-pVTZ level of theory and the resulting equilibrium structure optimized at the CCSD(T)/cc-pVQZ level. The total electronic energy was calculated at the complete basis set limit (extrapolated from aug-cc-

pVXZ (X = T, Q, 5)) energies, corrected for correlation contributions, the core correlation, the zero-point energy, diagonal Born-Oppenheimer contributions, and the scalar relativistic effect. The heat of formation was computed from the calculated enthalpies by using the elemental reaction approach, taking the gaseous atom as the standard state for carbon.¹² Previous values of $\Delta_f H_{298}^\circ = -445.6 \pm 1.7 \text{ kJ mol}^{-1}$ and $S^\circ = 287.3 \text{ J mol}^{-1}$ were from the Thermodynamics Research Center review.¹ Pedley review gives $-744.6 \pm 1.7 \text{ kJ mol}^{-1}$.¹³

CF₂CF₂ Enthalpy from review of Pedley.¹³

***anti*- and *gauche*-CHF₂CHF₂, 1,1,2,2-tetrafluoroethanes**

The conformationally averaged values are $\Delta_f H_{298}^\circ = -877.6 \pm 3.8 \text{ kJ mol}^{-1}$ and $S^\circ = 323.2 \pm 4.7 \text{ J mol}^{-1}$. Conformers and rotational barriers determined at the CCSD(T)/cc-pVTZ level of theory and the resulting equilibrium structure optimized at the CCSD(T)/cc-pVQZ level. The total electronic energy was calculated at the complete basis set limit (extrapolated from aug-cc-pVXZ (X = T, Q, 5)) energies, corrected for correlation contributions, the core correlation, the zero-point energy, diagonal Born-Oppenheimer contributions, and the scalar relativistic effect. The heat of formation was computed from the calculated enthalpies by using the elemental reaction approach, taking the gaseous atom as the standard state for carbon.¹² Previous $\Delta_f H_{298}^\circ = -860 \pm 24 \text{ kJ mol}^{-1}$ calculated based on the C-C bond strength estimate of $91.4 \pm 3.7 \text{ kcal mol}^{-1}$.¹⁰ Previous $S^\circ = 320.3 \text{ J mol}^{-1}$ from Thermodynamics Research Center review.⁵

CHF₂CF₃ Entropy calculated from molecular properties computed at the UHF/6-31* level of theory. Enthalpy derived from isodesmic reactions and adjusted down by 2 kJ mol^{-1} to reflect the enthalpy value for CH₂FCF₃ in this Table.⁴

CH₂FCF₃, 1,1,1,2-tetrafluoroethane

Conformers and rotational barriers determined at the CCSD(T)/cc-pVTZ level of theory and the resulting equilibrium structure optimized at the CCSD(T)/cc-pVQZ level. The total electronic energy was calculated at the complete basis set limit (extrapolated from aug-cc-pVXZ (X = T, Q, 5)) energies, corrected for correlation contributions, the core correlation, the zero-point energy, diagonal Born-Oppenheimer contributions, and the scalar relativistic effect. The heat of formation was computed from the calculated enthalpies by using the elemental reaction approach, taking the gaseous atom as the standard state for carbon.¹² Previous values of $\Delta_f H_{298}^\circ = -896 \pm 8 \text{ kJ mol}^{-1}$ (estimated) and $S^\circ = 316.2 \text{ J mol}^{-1}$ were from the Thermodynamics Research Center review.¹

CF₂CF₃ A dissociation energy of C₂F₅-I of $52.5 \pm 1 \text{ kcal mol}^{-1}$ was derived from a study of the reaction of pentafluoroethyl iodide with HI.¹⁷

CHF₂CF₃, pentafluoroethane

Conformers and rotational barriers determined at the CCSD(T)/cc-pVTZ level of theory and the resulting equilibrium structure optimized at the CCSD(T)/cc-pVQZ level. The total electronic energy was calculated at the complete basis set limit (extrapolated from aug-cc-pVXZ (X = T, Q, 5)) energies, corrected for correlation contributions, the core correlation, the zero-point energy, diagonal Born-Oppenheimer contributions, and the scalar relativistic effect. The heat of formation was computed from the calculated enthalpies by using the elemental reaction approach, taking the gaseous atom as the standard state for carbon.¹² Previous values of $\Delta_f H_{298}^\circ = -1105 \pm 5 \text{ kJ mol}^{-1}$ and $S^\circ = 333.7 \text{ J mol}^{-1}$ were from the Thermodynamics Research Center review.¹ Pedley review gives an enthalpy value of $-1100.4 \pm 4.1 \text{ kJ mol}^{-1}$.¹³

C₂F₆, hexafluoroethane

Enthalpy from a simultaneous solution of a thermochemical network for the CF₃X species, where X = nil, H, Cl, Br, I, CF₃, CN.¹⁵ Entropy from recommendation of Chen, et al.¹ A study in which conformers and rotational barriers determined at the CCSD(T)/cc-pVTZ level of theory and the resulting equilibrium structure optimized at the CCSD(T)/cc-pVQZ level. The total electronic energy was calculated at the complete basis set limit (extrapolated from aug-cc-pVXZ (X = T, Q, 5)) energies, corrected for correlation contributions, the core correlation, the zero-point energy, diagonal Born-Oppenheimer contributions, and the scalar relativistic effect

led to $\Delta_f H_{298}^\circ = -1339.8 \pm 3.2 \text{ kJ mol}^{-1}$ and $S^\circ = 331.0 \pm 1.5 \text{ J mol}^{-1}$. The heat of formation was computed from the calculated enthalpies by using the elemental reaction approach, taking the gaseous atom as the standard state for carbon.¹²

Note 27: Compounds containing two C and one or more F and O

[Back to Table](#)

CH₂FCH₂OH

The enthalpy of formation was calculated from a set of isodesmic and isogyric reactions at the CBS-QB3 level of theory and refers to the *gauche* configuration. Calculations with B3LYP/cc-pVTZ were in good agreement.²

CH₂FCOOH

The enthalpy of formation was calculated from a set of isodesmic and isogyric reactions at the CBS-QB3 level of theory. Calculations with B3LYP/cc-pVTZ were in good agreement.²

CF₃CO CBS-4 and G2(MP2,SVP) methods used to obtain thermodynamic properties. In addition, enthalpy was derived from isodesmic reaction calculations. Value listed is recommendation based on theoretical and experimental results. Entropy at the G2(MP2(full)//MP2(full)/6-31G(d) level treating internal rotations as harmonic oscillators.⁸

CF₃C(O)H Thermodynamic properties calculated at the G2(MP2(full)//MP2(full)/6-31G(d) level of theory. Enthalpy from atomization energy and entropy calculated treating internal rotations as harmonic oscillators. Similar values obtained at the CBS-4//HF/3021G* level.⁸

CH₃C(O)F, acetyl fluoride

Enthalpy value from review of Pedley.⁴

CF₃C(O)F Thermodynamic properties calculated for five isodesmic reactions at the MP2//6-31G(d) level of theory. In the same study, $\Delta H_f^\circ = -614 \pm 7$ kJ mol⁻¹ for CF₂O and $\Delta H_f^\circ = -381 \pm 2$ kJ mol⁻¹ for CHFO were calculated, both close to the recommended values.⁷

CF₃C(O)OH, trifluoroacetic acid

Enthalpy value from review of Pedley.⁴

CF₃OCO₂ An average of a result from an isodesmic reaction and an atomization energy, both calculated at the CBS-4 level of theory.³

CF₃OOCF₃

A thermal decomposition study from 575 to 900 K led to a BDE(O-O) of 47.5 ± 0.5 kcal mol⁻¹.⁵ An MP2//6-31G(d,p) calculation utilizing isodesmic and isogyric reactions resulted in -343 ± 3 kcal mol⁻¹.⁶ A CBS-QB3 calculation led to a BDE(O-O) of 209.4 kJ mol⁻¹, and thus an enthalpy of -1479 kJ mol⁻¹.¹

Note 28: Compounds containing more than two C and one or more F

[Back to Table](#)

iso-C₃H₇F Enthalpies of reaction calculated at the MCG3//MCQCISD level of theory (up to 6-311++G(3d2f,2df,2p) basis set) for the homolytic fragmentation to the alkyl radical and fluoride atom, and for the atomization reaction and averaged. Enthalpy also calculated for the heterolytic fragmentation into the alkyl cation and fluoride anion for support² $\Delta_f H_{298}^\circ = -318.8 \pm 4.2 \text{ kJ mol}^{-1}$ estimated by Luo and Benson.³

tert-C₄H₉F Enthalpies of reaction calculated at the MCG3//MCQCISD level of theory (up to 6-311++G(3d2f,2df,2p) basis set) for the homolytic fragmentation to the alkyl radical and fluoride atom, and for the atomization reaction and averaged. Enthalpy also calculated for the heterolytic fragmentation into the alkyl cation and fluoride anion for support.² $\Delta_f H_{298}^\circ = -363.6 \pm 4.2 \text{ kJ mol}^{-1}$ estimated by Luo and Benson.³

CF₃C(O)OCH₃

The free energy of formation of methyl trifluoroacetate in solution was determined by measuring the equilibrium constant for the reaction of trifluoroacetic acid with methanol. The solubility was estimated from a linear free-energy relationship and the vapor pressure estimated from the boiling point, leading to a value of the free energy of formation in the gas phase. Combining this with the estimate of the standard entropy, also listed, leads to the cited value.¹ A density-functional calculation at the MPWB1K//6-31+G(d,p) level with two isodesmic reactions, led to $\Delta_f H_{298}^\circ = -1020 \text{ kJ mol}^{-1}$.⁴

Note 29: Inorganic compounds containing Cl

[Back to Table](#)

Cl Enthalpy value is from the optimization of Ruscic et al.²⁰ Entropy is a CODATA Key Value⁴ as was the previous enthalpy value of $\Delta_f H_{298}^\circ = 121.301 \pm 0.008 \text{ kJ mol}^{-1}$.

Cl₂ CODATA Key Value⁴

HCl CODATA Key Value.⁴ The active thermochemical tables optimization gives an enthalpy value of $-92.1763 \pm 0.0063 \text{ kJ mol}^{-1}$.²⁰ The most recent NIST-JANAF review gives an enthalpy of $-92.31 \pm 0.10 \text{ kJ mol}^{-1}$ and an entropy of $186.901 \pm 0.005 \text{ J K}^{-1} \text{ mol}^{-1}$.²¹

ClO Both JANAF³ and Gurvich et al.⁹ use the dissociation energy from Coxan and Ramsay⁵ of $265.380 \pm 0.036 \text{ kJ mol}^{-1}$. The present recommendation is a recalculation using reference values from this Table. The entropy is a statistical mechanical calculation¹ using data from JANAF. The previous value of $101.63 \pm 0.1 \text{ kJ mol}^{-1}$ was from the JANAF recommendation.³ A CCSD(T) calculation, extrapolated to the complete basis set limit, for the atomization energy leads to an enthalpy of formation of $24.8 \text{ kcal mol}^{-1}$ at both 0 K and at 298 K.¹⁶ Another CCSD(T) calculation of the dissociation energy, both directly and through a negative ion thermochemical cycle, led to enthalpy values of $\Delta_f H_0^\circ = 24.1 \pm 0.3$ and $\Delta_f H_{298}^\circ = 24.1 \pm 0.3$

and 24.2 ± 0.3 kcal mol⁻¹.¹⁸ Atomization energy was calculated using the Wn family of computational methods. A slight increase in the atomization energy was found going from W2.2 to W4.4. These results led to $\Delta_f H_{298}^\circ = 101.2 \pm 0.4$ kJ mol⁻¹ and a 0 K value only 0.04 kJ mol⁻¹ higher.¹²

- CIOO** Enthalpy and entropy values are from an analysis of equilibrium constant measurements (see Table 3-1, Note 11). More recent measurements over the temperature range 212–245 K²³ support these values. Previous enthalpy value of 98 ± 4 kJ mol⁻¹ and entropy value of 269.32 ± 0.5 J K⁻¹ mol⁻¹ from JANAF. Enthalpy for the reaction $\text{HOOC} + \text{FOO} \rightarrow \text{HOOF} + \text{CIOO}$ at the CCSD(T)/CBS(Q5) level of theory, adjusted for the Table value for FOO, leads to $\Delta_f H_{298}^\circ = 103.9 \pm 6$ kJ mol⁻¹ and $\Delta_f H_0^\circ = 104.7 \pm 6$ kJ mol⁻¹.⁸ Atomization energy was calculated using the Wn family of computational methods. Significant increases in the atomization energy were found going from W2.2 to W4.4. These results led to $\Delta_f H_{298}^\circ = 101.7 \pm 0.7$ kJ mol⁻¹ and $\Delta_f H_0^\circ = 103.3 \pm 0.7$ kJ mol⁻¹.¹²
- CIOOH** Isodesmic reaction calculations done at MP2, CCSD, and CCSD(T) level with ANO basis sets to determine enthalpy of formation.¹⁴
- OCIO** Near-threshold fragmentation studies led to a dissociation energy to O + ClO of 247.3 ± 0.5 kJ mol⁻¹.⁶ This leads to an enthalpy of formation at 0 K of 100.6 ± 0.6 kJ mol⁻¹. A computational study gives, at 0 K, 102.2 ± 6.5 kJ mol⁻¹.¹³ Previous 298 K enthalpy of formation, 94.6 ± 1.2 , derived from equilibrium constant for $\text{ClO} + \text{ClO} \leftrightarrow \text{Cl} + \text{OCIO}$.¹⁷ Entropy and enthalpy function are from JANAF.³ A CCSD(T) calculation, extrapolated to the complete basis set limit, for the atomization energy leads to an enthalpy of formation of 24.5 kcal mol⁻¹ at 0 K and 23.9 at 298 K.¹⁶ An atomization energy calculated at the W4 level of theory led to $\Delta_f H_{298}^\circ = 99.0 \pm 0.7$ kJ mol⁻¹ and $\Delta_f H_0^\circ = 101.5 \pm 0.7$ kJ mol⁻¹.¹²
- CIO₃** A calculation of the isodesmic reaction $\text{ClO}_3 + \text{ClO} \rightarrow 2\text{OCIO}$ at the W4.2 level of theory provided the selected enthalpy values.¹² The previous values, $\Delta_f H_{298}^\circ = 194 \pm 12$ kJ mol⁻¹ and $\Delta_f H_0^\circ = 200 \pm 12$ kJ mol⁻¹ were the JANAF recommendations, which were based on limited kinetic and theoretical studies.³ A more recent density functional/G3 calculation led to a 298 K enthalpy of 43.1 kcal mol⁻¹ (= 180.3 kJ mol⁻¹).²²
- ClCIO** A CCSD(T), extrapolated to the complete basis set limit, for the atomization energy leads to the recommended enthalpy of formation and a value of 32.2 kcal mol⁻¹ at 0 K. For the ¹A' state. $\Delta_f H_{298}^\circ = 52.4 \pm 1$ kcal mol⁻¹ for the ³A" state.¹⁶ The previous recommendation, 90 ± 30 kJ mol⁻¹, from the JANAF evaluation,³ was based on an interpretation of the infrared spectrum and suggested that ClCIO was less stable than ClOCl by ~9 kJ mol⁻¹. Several computational studies cited in the JANAF review indicated that the stability difference was considerably greater, typically about 60 kJ mol⁻¹. The present recommendation leads to a stability difference of 52 kJ mol⁻¹. Entropy and enthalpy difference calculated by a statistical mechanical calculation using vibrational frequencies from the WebBook and PM3 rotational moments.¹
- CIOCl** Enthalpy value based on experimental reports on the equilibrium constant for the reaction $\text{H}_2\text{O} + \text{Cl}_2\text{O} \leftrightarrow 2\text{HOCl}$ and the recommended enthalpy of formation for HOCl.¹⁰ Gurvich et al. recommended an enthalpy of formation at 298 K of 79 ± 10 kJ mol⁻¹.⁹ A CCSD(T) calculation, extrapolated to the complete basis set limit, for the atomization energy leads to an enthalpy of formation of 19.3 kcal mol⁻¹ at 0 K and 18.9 at 298 K.¹⁶
- CIOOCl** Selected enthalpy value derived from a third-law calculation on the equilibrium constant for the dimerization reaction, $\text{ClO} + \text{ClO} \leftrightarrow \text{ClOOCl}$, presented in Table 3-1, note 20. Entropy value calculation is also discussed in Table 3-1. Previous Table value of $\Delta_f H_{298}^\circ$, 127.6 ± 2.9 kJ mol⁻¹, was from the equilibrium constant of Nickolasen, et al.¹⁷ and the entropy was the JANAF recommendation.³ A study of the fragmentation threshold of ClO⁺ from the photoionization of ClOOCl yielded a 0 K enthalpy of 134.07 ± 2.8 kJ mol⁻¹ and a 298 K value of 130.87 ± 2.8 kJ mol⁻¹.¹⁹ A CCSD(T) calculation, extrapolated to the complete basis set limit, for the atomization energy leads to an enthalpy of formation of 32.9 kcal mol⁻¹ at 0 K and 31.6 at 298 K.¹⁶ A calculation using the isodesmic reactions $\text{ClOOCl} + \text{H}_2\text{O} \rightarrow \text{H}_2\text{O}_2 + \text{Cl}_2\text{O}$ and

$\text{ClOOC} + 2\text{HOCl} \rightarrow \text{H}_2\text{O}_2 + 2\text{Cl}_2\text{O}$ at the W4.2 level of theory leads to $\Delta_f H_{298}^\circ = 131.8 \pm 1.3$ kJ mol⁻¹ and $\Delta_f H_0^\circ = 135.1 \pm 1.3$ kJ mol⁻¹.¹²

- ClClO₂** Derived from a CCSD(T) calculation, extrapolated to the complete basis set limit, for the atomization energy.¹⁶ See Table 3-1, note 21 for a more complete discussion. The previous value, 154.2 kJ mol⁻¹ (36.9 kcal mol⁻¹), was calculated at Gaussian-2 level of theory.¹⁵ Entropy from JANAF evaluation.³ The same value resulted from a statistical mechanical calculation.
- ClOCIO** Derived from a CCSD(T) calculation, extrapolated to the complete basis set limit, for the atomization energy¹⁶ combined with G2 composite calculations.²⁵ See Table 3-1, note 20b for a more complete discussion. The previous value, 175.5 kJ mol⁻¹ (41.9 kcal mol⁻¹), was calculated at Gaussian-2 level of theory¹⁵ and the previous entropy (309±2 kJ mol⁻¹) was from the JANAF evaluation.³
- Cl₂O₃** Selected enthalpy and entropy values derived from a third-law calculation on the equilibrium constant for the reaction, $\text{ClO} + \text{OCIO} \leftrightarrow \text{Cl}_2\text{O}_3$, presented in Table 3-1, note 15. Previous values in Table, $\Delta_f H = 35.8 \pm 1.5$ kcal mol⁻¹ and $\Delta S = 94 \pm 5$ cal K⁻¹ mol⁻¹, were taken from a single study.² The most stable structure among the Cl₂O₃ isomers is calculated to be ClOCl(O)O.²⁶ A density functional/G3 calculation led to a 298 K enthalpy of 31.7 kcal mol⁻¹.²²
- HOCl** Enthalpy value from an evaluation of the experimental data.¹⁰ Entropy and the enthalpy difference from JANAF evaluation.³ An enthalpy value of -18.1 ± 0.3 kcal mol⁻¹ has been calculated by coupled-cluster theory with correlation consistent basis sets and corrections for core-valence, relativistic, and anharmonic effects.⁷ A calculation of the isodesmic reaction $\text{HOF} + \text{OH} \rightarrow \text{FO} + \text{H}_2\text{O}$ at the W4.2 level of theory leads to $\Delta_f H_{298}^\circ = -76.1 \pm 0.6$ kJ mol⁻¹ and $\Delta_f H_0^\circ = -73.4 \pm 0.6$ kJ mol⁻¹.¹² A re-evaluation of the spectroscopic results, along with a newer value for the OH enthalpy, has led to a recommended value of $\Delta_f H_0^\circ = -73.99 \pm 0.12$ kJ mol⁻¹.¹¹
- HOCIO** A calculation of the isodesmic reaction $\text{HOCIO} + \text{ClO} \rightarrow \text{HOCl} + \text{OCIO}$ at the W4lite level of theory provided the selected enthalpy values.¹²
- HOCIO₂** The total atomization energy was calculated at the W2.2 level of theory and then corrected to provide an estimated W4lite value, leading to the selected enthalpy values.¹²
- HOCIO₃** The total atomization energy was calculated at the W2.2 level of theory, leading to the selected enthalpy values.¹²
- ClF** Taken from review of Gurvich et al.⁹ The JANAF Tables give $\Delta_f H_0^\circ = -50.2 \pm 0.4$ kJ mol⁻¹, $\Delta_f H_{298}^\circ = -50.3 \pm 0.4$ kJ mol⁻¹, and $S^\circ = 217.938$ J mol⁻¹.³ A study in which the total atomization energy was calculated using a composite electronic structure approach based on CCSD(T) and extrapolated to the complete basis set limit with a two-point extrapolation scheme, Q5. Additional corrections included zero-point energy, core-valence effect, for scalar relativistic effects, and spin-orbit corrections, gave $\Delta_f H_{298}^\circ = -54.8$ kJ mol⁻¹.²⁴
- ClOF** The total atomization energy was calculated using a composite electronic structure approach based on CCSD(T) and extrapolated to the complete basis set limit with a two-point extrapolation scheme, Q5. Additional corrections included zero-point energy, core-valence effect, for scalar relativistic effects, and spin-orbit corrections.²⁴
- ClO₂F** The total atomization energy was calculated using a composite electronic structure approach based on CCSD(T) and extrapolated to the complete basis set limit with a two-point extrapolation scheme, Q5. Additional corrections included zero-point energy, core-valence effect, for scalar relativistic effects, and spin-orbit corrections.²⁴

Note 30: Inorganic compounds containing Cl, O, and N

[Back to Table](#)

- ClNO** Taken from review of Gurvich et al.⁴ The JANAF Tables give $\Delta_f H_0^\circ = 53.6 \text{ kJ mol}^{-1}$, $\Delta_f H_{298}^\circ = 51.7 \text{ kJ mol}^{-1}$, and $S^\circ = 261.680 \text{ J mol}^{-1}$.²
- ClNO₂** The equilibrium geometry was calculated at the CCSD(T)/cc-pVQZ level of theory, while the energy was calculated by summing various contributions calculated at the CCSC(T) level with the use of various basis sets.⁸ The previous value, $\Delta_f H_{298}^\circ = 52.7 \pm 0.5 \text{ kJ mol}^{-1}$, was taken from review of Gurvich et al.⁴ The JANAF Tables give $\Delta_f H_0^\circ = 17.5 \text{ kJ mol}^{-1}$, $\Delta_f H_{298}^\circ = 12.1 \text{ kJ mol}^{-1}$, and $S^\circ = 272.187 \text{ J mol}^{-1}$.²
- cis-ClONO** The equilibrium geometry was calculated at the CCSD(T)/cc-pVQZ level of theory, while the energy was calculated by summing various contributions calculated at the CCSC(T) level with the use of various basis sets.⁸ The previous value, $\Delta_f H_{298}^\circ = 64.6 \text{ kJ mol}^{-1}$, was predicted based on isodesmic reactions at the CCSD(T) level of theory.⁵
- trans-ClONO**
The equilibrium geometry was calculated at the CCSD(T)/cc-pVQZ level of theory, while the energy was calculated by summing various contributions calculated at the CCSC(T) level with the use of various basis sets.⁸ The previous value, $\Delta_f H_{298}^\circ = 75.3 \text{ kJ mol}^{-1}$, was predicted based on isodesmic reactions at the CCSD(T) level of theory.⁵
- cis, perp-ClO₂NO**
Enthalpy calculated at MP2 level of theory using basis sets ranging from 6-31G(d) to 6-311G(2df,2p).⁷ A G3//B3LYP study gave enthalpies at 0 K and 298 K of 32.5 and 31.5 kcal mol⁻¹, respectively.⁶
- trans, perp-ClO₂NO**
Enthalpy calculated at MP2 level of theory using basis sets ranging from 6-31G(d) to 6-311G(2df,2p).⁷ A G3//B3LYP study gave enthalpies at 0 K and 298 K of 34.4 and 33.2 kcal mol⁻¹, respectively.⁶
- ClONO₂** The equilibrium geometry was calculated at the CCSD(T)/cc-pVQZ level of theory, while the energy was calculated by summing various contributions calculated at the CCSC(T) level with the use of various basis sets.⁸ The previous value, $\Delta_f H_{298}^\circ = 22.9 \pm 2.0 \text{ kJ mol}^{-1}$, was derived from a study of the thermal dissociation of ClONO₂.¹ Enthalpy values obtained from the atomization energy obtained using the G3//B3LYP level of theory are $\Delta_f H_0^\circ = 7.0 \text{ kcal mol}^{-1}$ and $\Delta_f H_{298}^\circ = 5.5 \text{ kcal mol}^{-1}$.⁶
- cis,perp-ClOONO**
The equilibrium geometry was calculated at the CCSD(T)/cc-pVQZ level of theory, while the energy was calculated by summing various contributions calculated at the CCSC(T) level with the use of various basis sets.⁸ The previous value, $\Delta_f H_{298}^\circ = 132 \text{ kJ mol}^{-1}$, was obtained from the atomization energy obtained using the G3//B3LYP level of theory.⁶
- trans, perp-ClOONO**
The equilibrium geometry was calculated at the CCSD(T)/cc-pVQZ level of theory, while the energy was calculated by summing various contributions calculated at the CCSC(T) level with the use of various basis sets.⁸ The previous value, $\Delta_f H_{298}^\circ = 132 \text{ kJ mol}^{-1}$, was obtained from the atomization energy obtained using the G3//B3LYP level of theory.⁶
- trans, perp-OCIONO**

Value obtained from the atomization energy obtained using the G3//B3LYP level of theory.⁶

O₂ClONO₂ Based on a study of the recombination of OCIO and NO₃, leading to a bond strength of 18±3 kcal mol⁻¹.³

NH₂Cl, NHCl₂, NCl₃, chloramines

Geometries were optimized at the (AE)-CCSD(T)/AVQZ level of theory and zero-point energies computed at the B2PLYPD/AVQZ level. For the electronic energies, a calculational protocol termed TA14 was adapted from the W3, W4, and FPD protocols. Enthalpies of formation were determined from the total atomization energies.⁹

[Back to Table](#)

CCl Geometry optimization was carried out at the CCSD(T) level of theory with the cc-pZQZ basis set. Enthalpy was calculated using the HEAT protocols, which involves summing a number of individual CCSD(T) energies with the basis set limited HF energy, along with other contributions.¹

CHCl Calculated for the X¹A' state. The triplet-singlet energy gap is estimated to be 2170±40 cm⁻¹. Enthalpy determined by calculating the enthalpy of the reaction CH₂ + HCl → HCCl + H₂. Calculations involved the focal-point approach, based on methods up to CCSDTQ and basis sets ranging from aug-cc-pVDZ to aug-cc-pV6Z, extrapolated to the complete basis set limit.¹² Enthalpy obtained using the computed enthalpy of a reaction of the type: CH₂(¹A₁) + CH₃X + CH₃Y ↔ CXY(¹A₁) + 2CH₄ results in Δ_fH₂₉₈⁰ = 320 kJ mol⁻¹ at the QCISD(T)/6-311+G(3df,2p)//QCISD/6-311G(d,p) level of theory. Calculations also done at the G2 level.⁹ Previous recommendation was based on combining experimental chloride dissociation energies from the parent anion, prior experimental measurements, and G2 calculations.⁷ Entropy values from Gurvich et al. review.² A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to Δ_fH₀⁰ = 320.1±2.3 kJ mol⁻¹, Δ_fH₂₉₈⁰ = 320.3±2.3 kJ mol⁻¹, and S = 234.6±1.5 J K⁻¹ mol⁻¹.¹ The enthalpy difference was used to calculate the 0 K value in the Table.

CH₂Cl Measured rate constant for the reaction of the radical with HBr, combined with previous measurements on the reverse reaction, with thermodynamic values obtained through a second-

law analysis.¹¹ A QCISD(T)/6-311+G(3df,2p) isodesmic study resulted in an enthalpy of $117.0 \pm 4.1 \text{ kJ mol}^{-1}$.¹⁰ A dissociative photoionization study of CH_2ClBr results in an enthalpy of $110.7 \text{ kJ mol}^{-1}$.⁵ A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to $\Delta_f H_0^\circ = 119.4 \pm 2.7 \text{ kJ mol}^{-1}$, $\Delta_f H_{298}^\circ = 116.0 \pm 2.7 \text{ kJ mol}^{-1}$, and $S = 236.3 \pm 1.5 \text{ J K}^{-1} \text{ mol}^{-1}$.¹ The enthalpy difference was used to calculate the 0 K value in the Table.

- CH₃Cl** Enthalpy from Manion evaluation.⁶ Entropy from Thermodynamics Research Center evaluation.⁸ A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to $\Delta_f H_0^\circ = -74.3 \pm 3.1 \text{ kJ mol}^{-1}$, $\Delta_f H_{298}^\circ = -82.6 \pm 3.1 \text{ kJ mol}^{-1}$, and $S = 234.0 \pm 1.5 \text{ J K}^{-1} \text{ mol}^{-1}$.¹ The enthalpy difference was used to calculate the 0 K value in the Table.
- CCl₂** Calculated for the X¹A' state. The triplet-singlet energy gap is estimated to be $7045 \pm 60 \text{ cm}^{-1}$. Enthalpy determined by calculating the enthalpy of the reaction $\text{CH}_2 + 2\text{HCl} \rightarrow \text{CCl}_2 + 2\text{H}_2$. Calculations involved the focal-point approach, based on methods up to CCSDTQ and basis sets ranging from aug-cc-pVDZ to aug-cc-pV6Z, extrapolated to the complete basis set limit.¹² Enthalpy obtained using the computed enthalpy of a reaction of the type: $\text{CH}_2(^1\text{A}_1) + \text{CH}_3\text{X} + \text{CH}_3\text{Y} \rightarrow \text{CXY}(^1\text{A}_1) + 2\text{CH}_4$ results in $\Delta_f H_{298}^\circ = 230 \text{ kJ mol}^{-1}$ at the QCISD(T)/6-311+G(3df,2p)/QCISD/6-311G(d,p) level of theory. Calculations also done at the G2 level.⁹ Previous recommendation ($55.0 \pm 2.0 \text{ kcal mol}^{-1}$) based on combining experimental chloride dissociation energies from the parent anion, prior experimental measurements, and G2 calculations.⁷ Entropy values from Gurvich et al. review.² A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to $\Delta_f H_0^\circ = 229.0 \pm 1.9 \text{ kJ mol}^{-1}$, $\Delta_f H_{298}^\circ = 230.1 \pm 1.9 \text{ kJ mol}^{-1}$, and $S = 264.5 \pm 1.5 \text{ J K}^{-1} \text{ mol}^{-1}$.¹ The enthalpy difference was used to calculate the 0 K value in the Table.
- CHCl₂** Measured rate constant for the reaction of the radical with HBr, combined with previous measurements on the reverse reaction, with thermodynamic values obtained through a second-law analysis.¹¹ A QCISD(T)/6-311+G(3df,2p) isodesmic study resulted in an enthalpy of $91.1 \pm 4.1 \text{ kJ mol}^{-1}$.¹⁰ A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to $\Delta_f H_0^\circ = 91.2 \pm 4.8 \text{ kJ mol}^{-1}$, $\Delta_f H_{298}^\circ = 88.8 \pm 5.8 \text{ kJ mol}^{-1}$, and $S = 280.7 \pm 6.5 \text{ J K}^{-1} \text{ mol}^{-1}$.¹ The enthalpy difference was used to calculate the 0 K value in the Table.
- CH₂Cl₂** Enthalpy from Manion evaluation.⁶ Entropy from Thermodynamics Research Center evaluation.⁸ A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to $\Delta_f H_0^\circ = -86.5 \pm 4.2 \text{ kJ mol}^{-1}$, $\Delta_f H_{298}^\circ = -93.7 \pm 4.2 \text{ kJ mol}^{-1}$, and $S = 269.7 \pm 1.5 \text{ J K}^{-1} \text{ mol}^{-1}$.¹ The enthalpy difference was used to calculate the 0 K value in the Table.
- CCl₃** A third-law determination based on the reaction $\text{CCl}_3 + \text{Br}_2 \leftrightarrow \text{CCl}_3\text{Br} + \text{Br}$, re-evaluating the kinetics of the reverse reaction and using spectroscopic data to calculate the entropy.⁴ A QCISD(T)/6-311+G(3df,2p) isodesmic study resulted in an enthalpy of $72.2 \pm 4.1 \text{ kJ mol}^{-1}$.¹⁰ A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to $\Delta_f H_0^\circ = 73.7 \pm 4.9 \text{ kJ mol}^{-1}$, $\Delta_f H_{298}^\circ = 73.1 \pm 4.9 \text{ kJ mol}^{-1}$, and $S = 301.3 \pm 1.5 \text{ J K}^{-1} \text{ mol}^{-1}$.¹ The enthalpy difference was used to calculate the 0 K value in the Table.
- CHCl₃** Enthalpy from Manion evaluation.⁶ Entropy from Thermodynamics Research Center evaluation.⁸ A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to $\Delta_f H_0^\circ = 94.6 \pm 5.3 \text{ kJ mol}^{-1}$, $\Delta_f H_{298}^\circ = -99.7 \pm 5.3 \text{ kJ mol}^{-1}$, and $S =$

294.8±1.5 J K⁻¹ mol⁻¹.¹ The enthalpy difference was used to calculate the 0 K value in the Table.

- CCl₄** Enthalpy from Manion evaluation.⁶ Entropy from Thermodynamics Research Center evaluation.⁸ A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to $\Delta_f H_0^\circ = -88.8 \pm 6.4$ kJ mol⁻¹, $\Delta_f H_{298}^\circ = -91.0 \pm 6.4$ kJ mol⁻¹, and $S = 308.6 \pm 1.5$ J K⁻¹ mol⁻¹.¹ The enthalpy difference was used to calculate the 0 K value in the Table. Experimental data from threshold PEPICO studies of halogenated methanes were combined with *ab initio* calculations of isodesmic and exchange reactions into a thermochemical network, leading to $\Delta_f H_0^\circ = -94.0 \pm 3.2$ kJ mol⁻¹.³

Note 32: Compounds containing one C and one or more Cl, H, and O

[Back to Table](#)

CClH₂O and CClH₂OH

The enthalpies of formation based on isodesmic reactions calculated at the MP2/6-31G(d,p) level of theory.¹¹

- CClO** Second- and third-law analyses of the equilibration kinetics for the reaction Cl + CO ↔ ClCO led to $\Delta_r H_{298}^\circ = -7.7 \pm 0.6$ kcal mol⁻¹, $\Delta_r H_0^\circ = -6.9 \pm 0.7$ kcal mol⁻¹, and $\Delta_r S_{298}^\circ = -23.8 \pm 2.0$ cal mol⁻¹ K⁻¹.⁹ See also Table 3-1, Note 12. (Previous enthalpy value had a sign error.) A shock-tube study of the thermal decomposition of COCl₂ led to a value of $\Delta_r H_0^\circ = -6.3 \pm 1.0$ kcal mol⁻¹.⁷ Entropy value cited derived by using standard statistical mechanic methods.⁹

- CHClO** The enthalpy values are taken from a CCSDT(Q) calculation, with structure optimized using the cc-pVQZ basis set.⁸ The previous $\Delta_f H_{298}^\circ = -164 \pm 20 \text{ kJ mol}^{-1}$ was estimated in the Gurvich et al. review.³ Entropy was based on spectroscopic studies.³
- CH₂OCl** Molecular properties determined at the MP2/6-31G(p,d), B3LYP/6-31G(d,p), and MP2/6-31G(d) level with single-point energy calculations at B3LYP/6-311+G(3df,2p) levels. Enthalpy based on four isodesmic reactions calculated at the CBS-Q//MP2/6-31(G(d,p) level.¹
- CH₃OCl** Molecular properties determined at the B3LYP/6-31G(d,p) level, with single-point calculations at this and the B3LYP/6-311+G(3df,2p), QCISD(T)/6-31G(d,p), and CBS-Q levels. Enthalpies determined using several working reactions.⁴
- CH₂ClO₂** Based on a re-analysis of previous equilibrium data on $R + O_2 \leftrightarrow RO_2$ from the same laboratory.⁵
- CH₂ClOOH** Molecular geometries determined at the B3LYP/6-31G(d,p) level of theory and electronic energies obtained through single-point calculations at the CBSQ level. Enthalpy of formation determined using five reaction schemes, three of which were isodesmic.¹³ A study in which geometry optimization and frequency calculations were performed at the MP2/6-31G(d) and the B3LYP/6-311++G(d,p) levels of theory, with a single-point energy calculation at the CCSD(T)/6-311++G(d,p)/B3LYP/6-311++G(d,p) level.⁶ The dissociation energy into HO₂ and the alkyl radical was then evaluated and used, after thermal correction, to calculate $\Delta_f H_{298}^\circ = -174 \text{ kJ mol}^{-1}$, after adjustment to the values for CH₃ and HO₂ from the present Table.
- CCl₂O** Taken from “The Chemical Thermodynamics of Organic Compounds”.¹² Pedley review gives an enthalpy value of $-219.1 \pm 0.5 \text{ kJ mol}^{-1}$.¹⁰
- CCl₂HO and CCl₂HOH** The enthalpies of formation are based on isodesmic reactions calculated at the MP2/6-31G(d,p) level of theory.¹¹
- CHCl₂O₂** Based on a re-analysis of previous equilibrium data on $R + O_2 \leftrightarrow RO_2$ from the same laboratory.⁵
- CH₂ClOCl** Molecular properties determined at the B3LYP/6-31G(d,p) level, with single-point calculations at this and the B3LYP/6-311+G(3df,2p), QCISD(T)/6-31G(d,p), and CBS-Q levels. Enthalpies determined using several working reactions.⁴
- CHCl₂OOH** Molecular geometries determined at the B3LYP/6-31G(d,p) level of theory and electronic energies obtained through single-point calculations at the CBSQ level. Enthalpy of formation determined using five reaction schemes, three of which were isodesmic.¹³
- CHCl₂OCl** Molecular properties determined at the B3LYP/6-31G(d,p) level, with single-point calculations at this and the B3LYP/6-311+G(3df,2p), QCISD(T)/6-31G(d,p), and CBS-Q levels. Enthalpies determined using several working reactions.⁴
- CCl₃O and CCl₃OH** Enthalpies of formation are based on isodesmic reactions calculated at the MP2/6-31G(d,p) level of theory.¹¹
- CCl₃O₂** Based on a re-analysis of previous equilibrium data on $R + O_2 \leftrightarrow RO_2$ from the same laboratory.⁵
- CCl₃OOH** Molecular geometries determined at the B3LYP/6-31G(d,p) level of theory and electronic energies obtained through single-point calculations at the CBSQ level. Enthalpy of formation determined using five reaction schemes, three of which were isodesmic.¹³
- CCl₃OCl** Molecular properties determined at the B3LYP/6-31G(d,p) level, with single-point calculations at this and the B3LYP/6-311+G(3df,2p), QCISD(T)/6-31G(d,p), and CBS-Q levels.

Enthalpies determined using several working reactions.⁴ $\Delta_f H_{298}^\circ = -146.6 \text{ kJ mol}^{-1}$ from a G2 calculation of the total energy of formation from the gas-phase elements.²

[Back to Table](#)

- CHFCI** Enthalpy derived from an analysis of thermochemical and kinetic data on the bromination of CH_2FCl .¹² A QCISD(T)/6-311+G(3df,2p) isodesmic study resulted in an enthalpy of $-63.8 \pm 4.1 \text{ kJ mol}^{-1}$.¹¹ A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to $\Delta_f H_0^\circ = -64.6 \pm 3.7 \text{ kJ mol}^{-1}$, $\Delta_f H_{298}^\circ = -67.8 \pm 4.7 \text{ kJ mol}^{-1}$, and $S = 273.5 \pm 6.5 \text{ J K}^{-1} \text{ mol}^{-1}$ (used in the Table).³ The enthalpy difference was used to calculate the 0 K value in the Table.
- CH₂FCI** Geometry optimization was carried out at the CCSD(T) level of theory with the cc-pZQZ basis set. Enthalpy was calculated using the HEAT protocols, which involves summing the CCSD(T) energy extrapolated to the complete basis set limit, along with several other contributions.³ Previous enthalpy from Pedley review⁷ and entropy from Thermodynamics Research Center review.¹
- CFCI** Recommendation based on combining experimental chloride dissociation energies from the parent anion, prior experimental measurements, and G2 calculations.⁸ Enthalpy obtained using the computed enthalpy of a reaction of the type: $\text{CH}_2(^1\text{A}_1) + \text{CH}_3\text{X} + \text{CH}_3\text{Y} \rightarrow \text{CXY}(^1\text{A}_1) + 2\text{CH}_4$ results in $\Delta_f H_{298}^\circ = 29.4 \text{ kJ mol}^{-1}$ at the QCISD(T)/6-311+G(3df,2p)//QCISD/6-

311G(d,p) level of theory. Calculations also done at the G2 level.¹⁰ Entropy values from Gurvich et al. review.⁴ A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to $\Delta_f H_0^\circ = 32.2 \pm 2.3 \text{ kJ mol}^{-1}$, $\Delta_f H_{298}^\circ = 32.0 \pm 2.3 \text{ kJ mol}^{-1}$, and $S = 258.9 \pm 1.5 \text{ J K}^{-1} \text{ mol}^{-1}$.³ The enthalpy difference was used to calculate the 0 K value in the Table.

- CF₂Cl** Geometry optimization was carried out at the CCSD(T) level of theory with the cc-pZQZ basis set. Enthalpy was calculated using the HEAT protocols, which involves summing the CCSD(T) energy extrapolated to the complete basis set limit, along with several other contributions.³ A photobromination study leads to $D(\text{CClF}_2\text{-H}) = 100.7 \pm 2 \text{ kcal mol}^{-1}$.⁶ A QCISD(T)/6-311+G(3df,2p) isodesmic study resulted in an enthalpy of $-274.7 \pm 4.1 \text{ kJ mol}^{-1}$.¹¹
- CFCl₂** Geometry optimization was carried out at the CCSD(T) level of theory with the cc-pZQZ basis set. Enthalpy was calculated using the HEAT protocols, which involves summing the CCSD(T) energy extrapolated to the complete basis set limit, along with several other contributions.³ An enthalpy of $-89.1 \pm 10 \text{ kJ mol}^{-1}$ was derived from an analysis of thermochemical and kinetic data on the bromination of CH_2FCl .¹² A QCISD(T)/6-311+G(3df,2p) isodesmic study resulted in an enthalpy of $-94.3 \pm 4.1 \text{ kJ mol}^{-1}$.¹¹
- CHFCl₂** Geometry optimization was carried out at the CCSD(T) level of theory with the cc-pZQZ basis set. Enthalpy was calculated using the HEAT protocols, which involves summing the CCSD(T) energy extrapolated to the complete basis set limit, along with several other contributions.³ Previous enthalpy value, from the Thermodynamics Research Center review,¹ was estimated.
- CHF₂Cl** Enthalpy from Pedley⁷ review and entropy from Thermodynamics Research Center review.¹ A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to $\Delta_f H_0^\circ = -475.7 \pm 3.1 \text{ kJ mol}^{-1}$, $\Delta_f H_{298}^\circ = -482.2 \pm 3.1 \text{ kJ mol}^{-1}$, and $S = 280.5 \pm 1.5 \text{ J K}^{-1} \text{ mol}^{-1}$.³ The enthalpy difference was used to calculate the 0 K value in the Table.
- CFCl₃** Enthalpy based on equilibrium measurements for the reaction $\text{CClF}_3 + 2\text{CCl}_4 \leftrightarrow 3\text{CCl}_3\text{F}$ leading to a heat of reaction of $10.59 \text{ kcal mol}^{-1}$, changed to reflect present enthalpy values.² Pedley review gives an enthalpy value of $-268.3 \pm 8.4 \text{ kJ mol}^{-1}$.⁷ A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to $\Delta_f H_0^\circ = -286.0 \pm 5.3 \text{ kJ mol}^{-1}$, $\Delta_f H_{298}^\circ = -282.7 \pm 5.3 \text{ kJ mol}^{-1}$, and $S = 308.6 \pm 1.5 \text{ J K}^{-1} \text{ mol}^{-1}$.³ The enthalpy difference was used to calculate the 0 K value in the Table. Experimental data from threshold PEPICO studies of halogenated methanes were combined with *ab initio* calculations of isodesmic and exchange reactions into a thermochemical network, leading to $\Delta_f H_0^\circ = -285.2 \pm 3.2 \text{ kJ mol}^{-1}$.⁵
- CF₂Cl₂** Enthalpy based on equilibrium measurements for the reaction $2\text{CClF}_3 + \text{CCl}_4 \leftrightarrow 3\text{CCl}_2\text{F}_2$ leading to a heat of reaction of $7.59 \text{ kcal mol}^{-1}$, changed to reflect present enthalpy values.² Pedley review gives an enthalpy value of $-477.4 \pm 7.2 \text{ kJ mol}^{-1}$.⁷ A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation using the HEAT protocols, led to $\Delta_f H_0^\circ = -487.9 \pm 4.2 \text{ kJ mol}^{-1}$, $\Delta_f H_{298}^\circ = -492.1 \pm 4.2 \text{ kJ mol}^{-1}$, and $S = 300.2 \pm 1.5 \text{ J K}^{-1} \text{ mol}^{-1}$.³ The enthalpy difference was used to calculate the 0 K value in the Table. Experimental data from threshold PEPICO studies of halogenated methanes were combined with *ab initio* calculations of isodesmic and exchange reactions into a thermochemical network, leading to $\Delta_f H_0^\circ = -487.8 \pm 3.4 \text{ kJ mol}^{-1}$.⁵
- CF₃Cl** Enthalpy from a simultaneous solution of a thermochemical network for the CF_3X species, where X = nil, H, Cl, Br, I, CF_3 , CN.⁹ Entropy from recommendation of the Thermodynamics Research Center.² A computational study with geometry optimization carried out at the CCSD(T) level of theory with the cc-pZQZ basis set, followed by an enthalpy calculation

using the HEAT protocols, led to $\Delta_f H_0^\circ = -703.4 \pm 3.1 \text{ kJ mol}^{-1}$, $\Delta_f H_{298}^\circ = -708.6 \pm 3.1 \text{ kJ mol}^{-1}$, and $S = 284.7 \pm 1.5 \text{ J K}^{-1} \text{ mol}^{-1}$.³ The enthalpy difference was used to calculate the 0 K value in the Table. Experimental data from threshold PEPICO studies of halogenated methanes were combined with *ab initio* calculations of isodesmic and exchange reactions into a thermochemical network, leading to $\Delta_f H_0^\circ = -702.1 \pm 3.5 \text{ kJ mol}^{-1}$.⁵

Note 34: *Compounds containing one C and one or more Cl, F, and O* [Back to Table](#)

CFCIO The enthalpy values are taken from a CCSDT(Q) calculation, with structure optimized using the cc-pVQZ basis set.⁷ Previous enthalpy value of $-429 \pm 20 \text{ kJ mol}^{-1}$ estimated in the Gurvich et al. review.⁵ The recommended entropy is taken from the Gurvich et al. review.

CF₃OCl Based on photoionization study. Enthalpy presented as lower limit.¹ A G2 calculation led to an enthalpy of $-768.3 \text{ kJ mol}^{-1}$.⁴

CCl₃OF Derived from a G2 calculation of the total energy of formation from the gas-phase elements.³

cis- and trans-FC(O)OCl

Enthalpy computed at the G3//B3LYP/6-311++G(3df,3pd) level of theory with both atomization energies and isodesmic reactions.²

CHClFOOH and CCl₂FOOH

Geometry optimization and frequency calculations were performed at the MP2/6-31G(d) and the B3LYP/6-311++G(d,p) levels of theory, with a single-point energy calculation at the CCSD(T)/6-311++G(d,p)/B3LYP/6-311++G(d,p) level. The dissociation energy into HO_2 and the alkyl radical was then evaluated and used, after thermal correction, to calculate the enthalpy of formation at 298 K.⁶ This was adjusted to the radical values from the present Table.

[Back to Table](#)

ClCH₂CH₂OH

The enthalpy of formation of the liquid was determined by using rotating-bomb combustion calorimetry to be $\Delta_f H_{298}^{\circ}(l) = -315.5 \pm 0.7$ kJ mol⁻¹. The molar enthalpy of vaporization was then determined by use of Calvert-drop microcalorimetry as $\Delta_{vap} H_{298}^{\circ} = 48.32 \pm 0.37$ kJ mol⁻¹.¹

CH₃CHClO₂

Based on a re-analysis of previous equilibrium data on $R + O_2 \leftrightarrow RO_2$ from the same laboratory.⁴

CH₃C(O)Cl, acetyl chloride

Enthalpy from review of Pedley.⁶

CH₂ClC(O)OH

Review of the literature.² Pedley review gives an enthalpy value of -435.2 ± 9.3 kJ mol⁻¹.⁶

CH₂ClCOOH

Geometries and frequencies calculated at the B3LYP/6-31G(d,p) level of theory. Enthalpy calculated from three isodesmic reactions at the CBSQ//B3LYP/6-31(Gd,p) level and corrected for mixing of rotational conformers.⁷

CH₃CHClOOH

Geometric parameters calculated at the RHF/6-31G* and MP2/6-31G* levels of theory, and the entropy obtained using the rigid-rotor/harmonic-oscillator approximation. Enthalpy calculated using the isodesmic reaction $\text{CH}_3\text{OOH} + \text{C}_2\text{H}_5\text{Cl} \leftrightarrow \text{CH}_3\text{CHClOOH} + \text{CH}_4$, adjusted with reference values from the present Table.⁵

CH₃CCl₂OOH

Geometric parameters calculated at the RHF/6-31G* and MP2/6-31G* levels of theory, and the entropy obtained using the rigid-rotor/harmonic-oscillator approximation. Enthalpy calculated using the isodesmic reaction $\text{CH}_3\text{OOH} + 1,1\text{-C}_2\text{H}_4\text{Cl}_2 \leftrightarrow \text{CH}_3\text{CCl}_2\text{OOH} + \text{CH}_4$, adjusted with reference values from the present Table.⁵

CH₂ClC(O)OCl, chloroacetyl chloride

Enthalpy value taken from review of Pedley.⁶

Cl(O)CC(O)Cl, ethanedioyl dichloride (oxalyl chloride)

Enthalpy value taken from review of Pedley.⁶

CHCl₂C(O)Cl, dichloroacetyl chloride

Enthalpy value taken from review of Pedley.⁶

CCl₃CH₂OOH

Geometries and frequencies calculated at the B3LYP/6-31G(d,p) level of theory. Enthalpy calculated from three isodesmic reactions at the CBSQ//B3LYP/6-31(Gd,p) level and corrected for mixing of rotational conformers.⁷

CCl₃CO

Enthalpy is an average of values obtained at the CBS-4//HF/3-21G* and G2(MP2(full)//MP2(full)/6-31G(d) levels of theory, using both atomization energies and formation from molecular species. Entropy at the G2(MP2(full)//MP2(full)/6-31G(d) level treating internal rotations as harmonic oscillators.⁸

CCl₃C(O)H

Thermodynamic properties calculated at the G2(MP2(full)//MP2(full)/6-31G(d) level of theory. Enthalpy from atomization energy and entropy calculated treating internal rotations as harmonic oscillators. Similar values obtained at the CBS-4//HF/3021G* level.⁸

CCl₃C(O)Cl, trichloroacetyl chloride

Enthalpy from review of Pedley.⁶

CH₃CCl₂O₂

Based on the equilibrium study using laser photolysis/PI mass spectrometry,³ adjusted by using the enthalpy for CH₃CCl₂ cited in this Table.

CHCl₂CH₂OOH

Geometries and frequencies calculated at the B3LYP/6-31G(d,p) level of theory. Enthalpy calculated from three isodesmic reactions at the CBSQ//B3LYP/6-31(Gd,p) level and corrected for mixing of rotational conformers.⁷

Note 39: Inorganic compounds containing Br

[Back to Table](#)

Br CODATA Key Value.²

$\text{Br}_2(\text{g})$ CODATA Key Value.² A calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit, leads to $\Delta_f H_{298}^\circ = 33.1 \pm 4 \text{ kJ mol}^{-1}$ and $\Delta_f H_0^\circ = 47.7 \pm 4 \text{ kJ mol}^{-1}$.⁵

HBr CODATA Key Value.² The most recent NIST-JANAF review gives and enthalpy of $-36.29 \pm 0.16 \text{ kJ mol}^{-1}$ and an entropy of $198.699 \pm 0.005 \text{ J K}^{-1} \text{ mol}^{-1}$.¹⁶

BrO Enthalpy derived from a photodissociation dynamics study using velocity map ion imaging.⁸ Previous enthalpy value of $30.2 \pm 0.4 \text{ kcal mol}^{-1}$ based on a Birge-Sponer extrapolation.¹⁸ Entropy from the JANAF table for bromine oxides.¹ A CCSD(T) calculation of the dissociation energy, both directly and thorough a negative ion thermochemical cycle, led to enthalpy values of $\Delta_f H_0^\circ = 31.4 \pm 0.4$ and $\Delta_f H_{298}^\circ = 29.6 \pm 0.4 \text{ kcal mol}^{-1}$.¹⁵ A calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit, leads to $\Delta_f H_{298}^\circ = 128 \pm 6 \text{ kJ mol}^{-1}$ and $\Delta_f H_0^\circ = 136 \pm 6 \text{ kJ mol}^{-1}$.⁵

OBrO Enthalpy based on the photoionization appearance energy of BrO^+ from OBrO, recalculated using the Table enthalpy for BrO .⁹ A newer computational study gives an enthalpy at 0 K of

163.9±7.1 kJ mol⁻¹.¹⁰ Entropy taken from the JANAF table for bromine oxides.¹ A calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit, leads to $\Delta_f H_{298}^\circ = 169.9 \pm 6$ kJ mol⁻¹ and $\Delta_f H_0^\circ = 179.5 \pm 6$ kJ mol⁻¹.⁵

BrOO Enthalpy for the reaction $\text{HOOBr} + \text{FOO} \rightarrow \text{HOOF} + \text{BrOO}$ at the CCSD(T)/CBS(Q5) level of theory, adjusted for the Table value for FOO, leads the cited enthalpy.⁵ An estimate based on recombination rate constants for bromine atoms and subsequent calculations of interaction potentials, leads to a bond strength of about 1 kcal mol⁻¹ and $\Delta_f H_{298}^\circ = 108 \pm 40$ kJ mol⁻¹ and $\Delta_f H_0^\circ = 116 \pm 10$ kJ mol⁻¹.¹ These results have been supported by other computational studies.^{14,17} CCSD(T)/AREP calculations predict, however, that BrOO lies below OBrO by about 5 kcal mol⁻¹, which appears to be inconsistent with these results.¹⁴ Entropy value is taken from NIST-JANAF thermochemical tables for bromine oxides.¹

BrO₃ Estimated values taken from the NIST-JANAF thermochemical tables for bromine oxides.¹

BrOBr Enthalpy derived from a photoionization study. This value was accepted by the NIST-JANAF thermochemical tables for bromine oxides, which also discussed three related studies and recommended the entropy value.¹ A CCSD(T)/ANO4 result based on the isodesmic reaction $2\text{HOBr} \rightarrow \text{H}_2\text{O} + \text{Br}_2\text{O}$, adjusted for the present enthalpy values for the references, gives 26.9 ± 1.6 kcal mol⁻¹.¹¹ A calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit, leads to $\Delta_f H_{298}^\circ = 108.4 \pm 6$ kJ mol⁻¹ and $\Delta_f H_0^\circ = 124.7 \pm 6$ kJ mol⁻¹.⁵

BrBrO The enthalpy is from a calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit. Listed value is for the ¹A' state. $\Delta_f H_{298}^\circ = 236.0 \pm 6$ kJ mol⁻¹ for the ³A" state and $\Delta_f H_{298}^\circ = 251.5 \pm 6$ kJ mol⁻¹ for the ³A' state.⁵ Entropy from the NIST-JANAF thermochemical tables for bromine oxides, which estimated the enthalpy as 168 ± 20 kJ mol⁻¹.¹

BrOOBr The enthalpy is from a calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit.⁵ Calculated enthalpy for the reaction $\text{BrO} + \text{BrO} \rightarrow \text{BrOOBr}$, $\Delta E = -16.93$ kcal mol⁻¹ by B3LYP/aug-cc-pVTZ method, leads to $\Delta_f H_{298}^\circ = 42.1$ kcal mol⁻¹.⁴ The dominant product observed in the matrix isolation/infrared spectroscopy study was BrOBrO.

BrOBrO The enthalpy is from a calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit.⁵ Calculated enthalpy for the reaction $\text{BrO} + \text{BrO} \rightarrow \text{BrOBrO}$, $\Delta E = -6.08$ kcal mol⁻¹ by B3LYP/aug-cc-pVTZ method, leads to $\Delta_f H_{298}^\circ = 52.9$ kcal mol⁻¹.⁴ The dominant product observed in the matrix isolation/infrared spectroscopy study was BrOBrO.

OBrBrO Calculated enthalpy for the reaction $\text{BrO} + \text{BrO} \rightarrow \text{OBrBrO}$, $\Delta E = +13.44$ kcal mol⁻¹ by B3LYP/aug-cc-pVTZ method.⁴ The dominant product observed in the matrix isolation/infrared spectroscopy study was BrOBrO.

BrBrO₂ The enthalpy is from a calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit.⁵

HOBr Enthalpy value from an evaluation of the experimental data.⁶ An enthalpy value of -15.3 ± 0.6 kcal mol⁻¹ has been calculated by coupled-cluster theory with correlation consistent basis sets and corrections for core-valence, relativistic, and anharmonic effects.³ Entropy value calculated from the experimental structure and vibrational frequencies.¹³ A re-evaluation of the photoionization results, along with a newer value for the OH enthalpy, led to a value of $\Delta_f H_0^\circ = -47.7 \pm 1.8$ kJ mol⁻¹.⁷

BrOOH CCSD(T) calculation with spdfig one-particle basis set, using isodesmic reaction and present values of reference enthalpies.¹²

HOBrO and HBrO₂

Isomerization energy calculated at CCSD(T)/ANO4 level of theory, corrected for zero-point energy and to 298 K. BrOOH energy from present table.¹²

BrF Taken from a review of the literature.¹ A calculation of the total atomization energy using a composite electronic structure approach based on CCSD(T) and extrapolated to the complete basis set limit with a two-point extrapolation scheme, Q5 led to a value of Δ_fH₂₉₈⁰ = -58.9 kJ mol⁻¹. Additional corrections included zero-point energy, core-valence effect, for scalar relativistic effects, and spin-orbit corrections.²

BrOF, BrO₂F

The total atomization energy was calculated using a composite electronic structure approach based on CCSD(T) and extrapolated to the complete basis set limit with a two-point extrapolation scheme, Q5. Additional corrections included zero-point energy, core-valence effect, for scalar relativistic effects, and spin-orbit corrections.²

Note 41: Inorganic compounds containing Br and Cl

[Back to Table](#)

- BrCl** Review of the literature.² A calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit, leads to $\Delta_f H_{298}^\circ = 15.9 \pm 6 \text{ kJ mol}^{-1}$ and $\Delta_f H_0^\circ = 23.4 \pm 6 \text{ kJ mol}^{-1}$.¹
- ClOBr** The enthalpy is from a calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit.¹ A CCSD(T)/ANO4 study, based on the isodesmic reaction $\text{HOBr} + \text{HOCl} \rightarrow \text{H}_2\text{O} + \text{ClOBr}$, adjusted for the present enthalpy values for the references, led to $\Delta_f H_{298}^\circ = 98 \pm 7 \text{ kJ mol}^{-1}$.³
- ClBrO** The enthalpy is from a calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit. $\Delta_f H_{298}^\circ = 145.2 \pm 6 \text{ kJ mol}^{-1}$ for the $^3\text{A}''$ state and $\Delta_f H_{298}^\circ = 252.7 \pm 6 \text{ kJ mol}^{-1}$ for the $^3\text{A}'$ state.¹
- BrClO** The enthalpy is from a calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit. Listed enthalpy is for the $^1\text{A}'$ state. $\Delta_f H_{298}^\circ = 226.4 \pm 6 \text{ kcal mol}^{-1}$ for the $^3\text{A}'$ state.¹
- ClOBr, BrOBrO, BrOCIO, ClBrO₂, BrClO₂**
The enthalpy values are from calculations of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit.¹

[Back to Table](#)

- BrNO** Taken from the NBS thermochemical tables.⁶ A CCSD(T)/ANO4 result based on the homodesmic reaction $\text{BrNO} + \text{H}_2\text{O} \rightarrow \text{HNO} + \text{HOBr}$, adjusted for the present enthalpy values for the references, gives $22.7 \pm 1.9 \text{ kcal mol}^{-1}$.¹
- cis-BrONO** Calculated using the isodesmic reaction $\text{H}_2\text{O} + \text{cis-BrONO} \rightarrow \text{cis-HONO} + \text{HOBr}$ at several levels of theory, leading to a reaction enthalpy of $7.6 \text{ kcal mol}^{-1}$.²
- trans-BrONO** Based on a calculated energy difference above BrNO_3 of $10.3 \text{ kcal mol}^{-1}$ from calculations at several levels of theory.²
- BrNO₂** Based on a calculated energy difference below *cis*-BrONO of $6.4 \text{ kcal mol}^{-1}$ from calculations at several levels of theory.²
- BrONO₂** The study of the thermal decomposition of BrONO_2 to BrO and NO_2 was used to obtain a reaction enthalpy of $28.2 \pm 1.5 \text{ kcal mol}^{-1}$ ($118 \pm 6.3 \text{ kJ mol}^{-1}$).³ A computational study at the CCSD(T) level with a TZ2P basis set involving several isodesmic reactions⁴ led to a value of

$\Delta_f H_{298}^\circ = 42.3 \text{ kJ mol}^{-1}$ whereas a CCSD(T)/cc-pV5Z calculation, extrapolated to the basis set limit, led to a BDE of $125.3 \text{ kJ mol}^{-1}$.⁷

Note 44: Compounds containing one C and one or more Br

[Back to Table](#)

- CBr** Enthalpy from a CCSD(T) calculation extrapolated to the CBS limit.² A calculation at the W2DK level of theory gave an enthalpy of $118.51 \text{ kcal mol}^{-1}$.⁷ Entropy obtained from the same study, using a DFT approach (B97-1/Aug-cc-pVTZ) for geometry optimization and frequency calculations.
- CHBr** Enthalpy from a CCSD(T) calculation extrapolated to the CBS limit.² A calculation at the DK-CCSD(T)/Aug-VTZ level, utilizing methyl bromide in an isodesmic reaction, resulted in an enthalpy value of $90.12 \text{ kcal mol}^{-1}$.⁷ Entropy obtained from the same study, using a DFT approach (B97-1/Aug-cc-pVTZ) for geometry optimization and frequency calculations. Enthalpy obtained using the computed enthalpy of a reaction of the type: $\text{CH}_2(^1\text{A}_1) + \text{CH}_3\text{X} + \text{CH}_3\text{Y} \rightarrow \text{CXY}(^1\text{A}_1) + 2\text{CH}_4$ results in $\Delta_f H_{298}^\circ = 380 \text{ kJ mol}^{-1}$ at the QCISD(T)/6-311+G(3df,2p)//QCISD/6-311G(d,p) level of theory. Calculations also done at the G2 level.¹⁰
- CH₂Br** Measured rate constant for the reaction of the radical with HBr, combined with previous measurements on the reverse reaction, with thermodynamic values obtained through a second-law analysis.¹¹ Recalculated from C-H bond strength of $427.2 \text{ kJ mol}^{-1}$ and enthalpy for CH₃Br and H from this Table. Statistical thermodynamic methods also utilized. *Ab initio* calculations at the QCISD(T)/6-311+G(3df,2p) level of theory, utilizing an isodesmic reaction with methyl bromide, resulted in an enthalpy value of $166.6 \pm 3 \text{ kJ mol}^{-1}$.⁶

- CH₃Br** Calculated from the dissociation of energy-selected CH₃Br⁺ and its adiabatic ionization energy.¹² Enthalpy from Gurvich et al. review is -36.4 ± 0.5 kJ mol⁻¹.³ Entropy taken from Ideal Gas Thermodynamic Properties, which gives an enthalpy of -37.7 ± 1.5 kJ mol⁻¹.⁴ Pedley review gives an enthalpy of -35.4 ± 1.1 kJ mol⁻¹.⁹
- CBr₂** Enthalpy from a CCSD(T) calculation extrapolated to the CBS limit.² Enthalpy obtained using the computed enthalpy of a reaction of the type: CH₂(¹A₁) + CH₃X + CH₃Y → CXY(¹A₁) + 2CH₄ results in $\Delta_f H_{298}^\circ = 339$ kJ mol⁻¹ at the QCISD(T)/6-311+G(3df,2p)//QCISD/6-311G(d,p) level of theory. Calculations also done at the G2 level.¹⁰ A calculation at the W2DK level of theory gave an enthalpy of 82.10 kcal mol⁻¹.⁷ Entropy obtained from the same study, using a DFT approach (B97-1/Aug-cc-pVTZ) for geometry optimization and frequency calculations.
- CHBr₂** Enthalpy derived from an analysis of thermochemical and kinetic data on the bromination of CH₂FCl.¹³ *Ab initio* calculations at the QCISD(T)/6-311+G(3df,2p) level of theory, utilizing an isodesmic reaction with methyl bromide, resulted in an enthalpy value of 191.7 ± 6 kJ mol⁻¹.⁶ A calculation at the DK-CCSD(T)/Aug-VTZ level, again utilizing methyl bromide in an isodesmic reaction, resulted in an enthalpy value of 47.44 kcal mol⁻¹.⁷ Entropy obtained from the same study, using a DFT approach (B97-1/Aug-cc-pVTZ) for geometry optimization and frequency calculations.
- CH₂Br₂** Enthalpy taken from a dissociative photoionization study of a series of dihalomethanes, normalized using the experimental enthalpy of dichloromethane.⁵ The reported value has been adjusted by +0.4 kJ mol⁻¹ to agree with the present enthalpy for CH₂Cl₂. Previous value of -11.1 kJ mol⁻¹ from Allen bond-energy scheme.¹ *Ab initio* calculations at the QCISD(T)/6-311+G(3df,2p) level of theory, utilizing an isodesmic reaction with methyl bromide, resulted in an enthalpy value of 4.3 ± 6 kJ mol⁻¹.⁶ Entropy from evaluation of Gurvich et al.³
- CBr₃** Enthalpy value from *ab initio* calculations at the QCISD(T)/6-311+G(3df,2p) level of theory, utilizing an isodesmic reaction with methyl bromide.⁶ A calculation at the DK-CCSD(T)/Aug-VTZ level, again utilizing methyl bromide in an isodesmic reaction, resulted in an enthalpy value of 55.50 kcal mol⁻¹.⁷ This same study, using a DFT approach for geometry optimization and frequency calculations, reported an entropy value of 80.60 cal K⁻¹. Gurvich et al. review has 235 ± 25 kJ mol⁻¹. Entropy from Gurvich et al.³
- CHBr₃** Enthalpy of formation derived from the heat of combustion of the liquid of 545.1 ± 3.3 kJ mol⁻¹ measured by bomb calorimetry.⁸ An enthalpy value of 51.6 ± 9 kJ mol⁻¹ was obtained from *ab initio* calculations at the QCISD(T)/6-311+G(3df,2p) level of theory, utilizing an isodesmic reaction with methyl bromide.⁶ A calculation at the DK-CCSD(T)/Aug-VTZ level, again utilizing methyl bromide in an isodesmic reaction, resulted in an enthalpy value of 12.97 kcal mol⁻¹.⁷ This same study, using a DFT approach for geometry optimization and frequency calculations, reported an entropy value of 78.93 cal K⁻¹. Previous value of 5.7 kcal mol⁻¹ from Allen bond-energy scheme.¹ Entropy from evaluation of Gurvich et al.³ Pedley gives enthalpy as 23.8 ± 4.5 kJ mol⁻¹.⁹
- CBr₄** Enthalpy from rotation-bomb calorimetry.¹ *Ab initio* calculations at the QCISD(T)/6-311+G(3df,2p) level of theory, utilizing an isodesmic reaction with methyl bromide, resulted in an enthalpy value of 110.6 ± 12 kJ mol⁻¹.⁶ A calculation at the DK-CCSD(T)/Aug-VTZ level, again utilizing methyl bromide in an isodesmic reaction, resulted in an enthalpy value of 28.49 kcal mol⁻¹.⁷ This same study, using a DFT approach for geometry optimization and frequency calculations, reported an entropy value of 85.61 cal K⁻¹. Entropy from Gurvich et al.³

CBr₂O, carbonyl bromide

Enthalpy from review of Pedley.⁴

CBr₃O Derived from a G2 calculation of the total energy of formation from the gas-phase elements.¹

CBr₃OX (X=H,F,Cl,Br)

Derived from a G2 calculation of the total energy of formation from the gas-phase elements.²

CCl₃OBr Derived from a G2 calculation of the total energy of formation from the gas-phase elements.²

CH₂BrOOH, CHFBrOOH, CHClBeOOH

Geometry optimization and frequency calculations were performed at the MP2/6-31G(d) and the B3LYP/6-311++G(d,p) levels of theory, with a single-point energy calculation at the CCSD(T)/6-311++G(d,p)//B3LYP/6-311++G(d,p) level. The dissociation energy into HO₂ and the alkyl radical was then evaluated and used, after thermal correction, to calculate the enthalpy of formation at 298 K.³ This was adjusted to the radical values from the present Table.

[Back to Table](#)

C₂Br An *ab initio* calculation at the W2DK level of theory.⁹ Entropy obtained from the same study, using a DFT approach (B97-1/Aug-cc-pVTZ) for geometry optimization and frequency calculations.

C₂HBr, bromoacetylene

Enthalpy from measurements of the photodissociation of bromoacetylene, leading to dissociation energy of 91.0±1.2 kcal mol⁻¹.⁸ Δ_fH₀^o = 71.3±1.5 kcal mol⁻¹. A calculation at the W2DK level of theory gave an enthalpy of 67.50 kcal mol⁻¹.⁹ Entropy obtained from the same study, using a DFT approach (B97-1/Aug-cc-pVTZ) for geometry optimization and frequency calculations.

C₂CHBr Enthalpy from review of Pedley.¹⁰ An enthalpy of 74.1±3.1 kJ mol⁻¹ has been derived from a dissociative photoionization study of CH₂BrCHBr₂ with a computed vinyl cation enthalpy.⁵

CH₂CH₂Br

An experimental study of the reaction Br + C₂H₄ ↔ C₂H₄Br led to an enthalpy of reaction of 6.8±1.6 kcal mol⁻¹.¹

CH₃CHBr A photobromination study leads to D(CH₃CHBr-H) = 97.2±1 kcal mol⁻¹.⁶

CH₃CH₂Br

Enthalpy obtained from a TPEPICO determination of the onset energy of the ethyl cation from the photodissociation of ethyl bromide, taking $\Delta_f H_0^\circ(\text{C}_2\text{H}_5^+) = 915.5 \pm 1.3 \text{ kJ mol}^{-1}$.² Previous enthalpy value, $-61.5 \pm 1.0 \text{ kJ mol}^{-1}$, was taken from review of the literature.³ Entropy calculated by Kudchadker and Kudchadker.⁴

C₂Br₂

An *ab initio* calculation at the W2DK level of theory.⁹ Entropy obtained from the same study, using a DFT approach (B97-1/Aug-cc-pVTZ) for geometry optimization and frequency calculations.

trans-CHBrCBr, trans-dibromovinyl radical

A calculation at the DK-CCSD(T)/Aug-VTZ level, utilizing methyl bromide in an isodesmic reaction.⁹ Entropy obtained from the same study, using a DFT approach (B97-1/Aug-cc-pVTZ) for geometry optimization and frequency calculations.

CH₃CBr₂ A photobromination study leads to $D(\text{CClF}_2\text{-H}) = 94.9 \pm 1.2 \text{ kcal mol}^{-1}$.⁷

CH₃CBr₂H Taken from a review of the literature.³

CHBrCBr₂, tribromoethene

A calculation at the DK-CCSD(T)/Aug-VTZ level, utilizing methyl bromide in an isodesmic reaction.⁹ Entropy obtained from the same study, using a DFT approach (B97-1/Aug-cc-pVTZ) for geometry optimization and frequency calculations.

CH₂BrCH₂Br

Enthalpy from review of Pedley.¹⁰

C₂Br₃

A calculation at the DK-CCSD(T)/Aug-VTZ level, utilizing methyl bromide in an isodesmic reaction.⁹ Entropy obtained from the same study, using a DFT approach (B97-1/Aug-cc-pVTZ) for geometry optimization and frequency calculations.

CH₂BrCHBr₂

Enthalpy derived from a dissociative photoionization study of CH₂BrCHBr₂ and a computed vinyl cation enthalpy.⁵

CH₃CBr₃ Taken from a Thermodynamics Research Center review. Enthalpy estimated.⁴

C₂Br₄, CHBr₂CBr₂, CBr₃CHBr, C₂Br₅, C₂Br₆

A calculation at the DK-CCSD(T)/Aug-VTZ level, utilizing methyl bromide in an isodesmic reaction.⁹ Entropy obtained from the same study, using a DFT approach (B97-1/Aug-cc-pVTZ) for geometry optimization and frequency calculations.

[Back to Table](#)

- IO** The photodissociation dynamics of expansion-cooled IO was investigated, using velocity map ion imaging. This led to $D_0 = 54.9 (+0.2 -0.4) \text{ kcal mol}^{-1}$ and to the recommended enthalpy values.³ Previous recommendation of the enthalpy, $\Delta_f H_0^\circ = 127.2 \pm 2.5 \text{ kJ mol}^{-1}$, $\Delta_f H_{298}^\circ = 125.1 \pm 2.5 \text{ kJ mol}^{-1}$, was from a CCSD(T) calculation of the dissociation energy, both directly and thorough a negative ion thermochemical cycle.¹⁰ The NIST-JANAF thermochemical tables for iodine oxides recommends $\Delta_f H_{298}^\circ = 126 \pm 18 \text{ kJ mol}^{-1}$ and $\Delta_f H_0^\circ = 128 \pm 18 \text{ kJ mol}^{-1}$, based on molecular beam studies.² The earlier spectroscopic studies are also discussed here. An equilibrium constant derived from the forward and reverse rate constants for $\text{IO} + \text{ClO} \leftrightarrow \text{I} + \text{OClO}$ leads to an enthalpy at 298 K of about $28.6 \text{ kcal mol}^{-1}$ (using reference values from this table) and $27.5 \text{ kcal mol}^{-1}$ from the equilibrium $\text{Cl} + \text{IO} \leftrightarrow \text{I} + \text{ClO}$.¹ Enthalpy of reaction obtained using CCSD(T) calculations at B3LYP geometries, with corrections for spin-orbit coupling, for $\text{I} + \text{O} \rightarrow \text{IO}$, using Table reference values, leads to $\Delta_f H_{298}^\circ = 117.3 \text{ kJ mol}^{-1}$.⁷ A calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit, leads to $\Delta_f H_{298}^\circ = 128.0 \pm 6 \text{ kJ mol}^{-1}$ and $\Delta_f H_0^\circ = 130.1 \pm 6 \text{ kJ mol}^{-1}$.⁵ Entropy based on extensive calculations.⁶
- OIO** The enthalpy value was from a determination of the threshold for the appearance of IO upon pulsed photolysis of OIO, indicating a bond strength of $D_0(\text{O}-\text{IO}) = 248.8 \pm 1 \text{ kJ mol}^{-1}$.⁴ The previous values of $\Delta_f H_{298}^\circ = 117.7 \pm 6 \text{ kJ mol}^{-1}$ and $\Delta_f H_0^\circ = 123.4 \pm 6 \text{ kJ mol}^{-1}$ were from a calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit.⁵ Molecular properties calculated at the MP2/6-31G(d) and MP2/6-311+G(3df) levels of theory provided the entropy and, with this information, an enthalpy of $\Delta_f H_{298}^\circ = 75 \text{ kJ mol}^{-1}$ was derived using approximate QCISD(T)/6-311+G93df energies coupled with isodesmic reactions.⁹ A more recent computational study gives an enthalpy at 0 K of $113.9 \pm 10.3 \text{ kJ mol}^{-1}$.⁸ Enthalpy of reaction obtained using CCSD(T) calculations at B3LYP geometries, with corrections for spin-orbit coupling, for $2\text{IO} \rightarrow \text{OIO} + \text{I}$ leads to a 298 K enthalpy of $110.1 \text{ kJ mol}^{-1}$.⁷
- IOO** Enthalpy for the reaction $\text{HOOI} + \text{FOO} \rightarrow \text{HOOF} + \text{IOO}$ at the CCSD(T)/CBS(DTQ) level of theory, adjusted for the Table value for FOO, leads the cited enthalpy.⁵ Entropy from molecular properties calculated at the MP2/6-31G(d) and MP2/6-311+G(3df) levels of theory and, with this information, an enthalpy of $\Delta_f H_{298}^\circ = 96 \text{ kJ mol}^{-1}$ was derived using approximate QCISD(T)/6-311+G93df energies coupled with isodesmic reactions.⁹
- IO₃** Enthalpy at 298 K of reaction obtained using CCSD(T) calculations at B3LYP geometries, with corrections for spin-orbit coupling, for $\text{OIO} + \text{IO}_3 \rightarrow \text{I}_2\text{O}_5$.⁷ Entropy and enthalpy difference from NIST-JANAF thermochemical tables for iodine oxides.² Previous enthalpy value of 242 kJ mol^{-1} was estimated.

- IOI** The enthalpy is from a calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit.⁵ Entropy from molecular properties calculated at the MP2/6-31G(d) and MP2/6-311+G(3df) levels of theory and, with this information, an enthalpy of $\Delta_f H_{298}^\circ = 92.5 \pm 17 \text{ kJ mol}^{-1}$ was derived using approximate QCISD(T)/6-311+G93df) energies coupled with isodesmic reactions.⁹
- IIO** The enthalpy is from a calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit. Listed value is for the $^1A'$ state. $\Delta_f H_{298}^\circ = 234.3 \pm 6 \text{ kJ mol}^{-1}$ for the 3A_2 state.⁵ Entropy from molecular properties calculated at the MP2/6-31G(d) and MP2/6-311+G(3df) levels of theory and, with this information, an enthalpy of $\Delta_f H_{298}^\circ = 134 \pm 17 \text{ kJ mol}^{-1}$ was derived using approximate QCISD(T)/6-311+G93df) energies coupled with isodesmic reactions.⁹
- IOOI** The enthalpy is from a calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit.⁵ Entropy from molecular properties calculated at the MP2/6-31G(d) and MP2/6-311+G(3df) levels of theory and, with this information, an enthalpy of $\Delta_f H_{298}^\circ = 157 \text{ kJ mol}^{-1}$ was derived using approximate QCISD(T)/6-311+G93df) energies coupled with isodesmic reactions.⁹ Enthalpy of reaction obtained using CCSD(T) calculations at B3LYP geometries, with corrections for spin-orbit coupling, for $IO + IO \rightarrow IOOI$ leads to a 298 K enthalpy of $179.9 \text{ kJ mol}^{-1}$.⁷
- IIO₂** The enthalpy is from a calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit.⁵ Entropy from molecular properties calculated at the MP2/6-31G(d) and MP2/6-311+G(3df) levels of theory and, with this information, an enthalpy of $\Delta_f H_{298}^\circ = 103 \text{ kJ mol}^{-1}$ was derived using approximate QCISD(T)/6-311+G93df) energies coupled with isodesmic reactions.⁹ Enthalpy of reaction obtained using CCSD(T) calculations at B3LYP geometries, with corrections for spin-orbit coupling, for $IO + IO \rightarrow IIO_2$, using Table reference values, leads to a 298 K enthalpy of $157.9 \text{ kJ mol}^{-1}$.⁷
- IOIO** The enthalpy is from a calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit.⁵ Entropy from molecular properties calculated at the MP2/6-31G(d) and MP2/6-311+G(3df) levels of theory and, with this information, an enthalpy of $\Delta_f H_{298}^\circ = 124 \text{ kJ mol}^{-1}$ was derived using approximate QCISD(T)/6-311+G93df) energies coupled with isodesmic reactions.⁹ Enthalpy of reaction obtained using CCSD(T) calculations at B3LYP geometries, with corrections for spin-orbit coupling, for $IO + IO \rightarrow IOIO$ leads to a 298 K enthalpy of $141.3 \text{ kJ mol}^{-1}$.⁷
- OIIO** The enthalpy is from a calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit.⁵ Molecular properties calculated at the MP2/6-31G(d) and MP2/6-311+G(3df) levels of theory. Enthalpy derived using approximate QCISD(T)/6-311+G93df) energies coupled with isodesmic reactions gives $\Delta_f H_{298}^\circ = 224 \text{ kJ mol}^{-1}$.⁹
- I₂O₃** Enthalpy of reaction obtained using CCSD(T) calculations at B3LYP geometries, with corrections for spin-orbit coupling, for $IO + OIO \rightarrow I_2O_3$.⁷
- I₂O₄** Enthalpy of reaction obtained using CCSD(T) calculations at B3LYP geometries, with corrections for spin-orbit coupling, for $2OIO \rightarrow I_2O_4$.⁷
- I₂O₅** Enthalpy of reaction obtained using CCSD(T) calculations at B3LYP geometries, with corrections for spin-orbit coupling, for $I_2O_4 + O_3 \rightarrow I_2O_5 + O$.⁷

- HOI** Reaction enthalpies for a set of isogyric reactions were calculated using CR-CCSD(T) with single and double excitation and with second-order spin-free Douglas-Kroll-Hess Hamiltonian applied to account for the scalar relativistic effects. The listed values are from a recalculation using the present Table values, which are particularly different for IO and OH. The authors report: $\Delta_f H_{298}^\circ = -69.0 \pm 3.7 \text{ kJ mol}^{-1}$.⁶ A computational study of the OH + CH₂BrI → HOI + CH₂Br reaction at the DK-CCSD(T)/ANO-RCC-L(1)/MP2/ccpVTZ level of theory led to $\Delta_f H_{298}^\circ = -62.9 \text{ kJ mol}^{-1}$.⁵ The previous values of $\Delta_f H_{298}^\circ = -69.6 \pm 5.4 \text{ kJ mol}^{-1}$ and $\Delta_f H_0^\circ = -64.9 \pm 5.4 \text{ kJ mol}^{-1}$ was based on the measured activation energy of the reaction OH + CF₃I → CF₃ + HOI and G2(MP2) calculation indicating a negligible barrier for the reverse reaction.² Entropy based on extensive calculations.³ Enthalpy values have also been calculated using the isogyric reaction HOOH + IO → HOO + HOI with density functional theory (GP96PW91 level), leading to $-58.6 \text{ kJ mol}^{-1}$ and $-63.3 \text{ kJ mol}^{-1}$ at 0 and 298 K, employing reference enthalpies from this Table.¹ A calculation involving a pair of isodesmic reactions at the CCSD(T) level of theory in conjunction with the aug-cc-pVTZ-PP and aug-cc-pVQZ-PP basis sets led to $\Delta_f H_{298}^\circ = -59.2 \pm 3.9 \text{ kJ mol}^{-1}$ and $\Delta_f H_0^\circ = -54.5 \pm 3.9 \text{ kJ mol}^{-1}$.⁴
- HIO** Enthalpy difference calculated HOI → HIO with density functional theory (GP96PW91 level).¹
- HOIO** Enthalpy difference calculated HOOI → HOIO with density functional theory (GP96PW91 level), $\Delta_f H_0^\circ = -11.0 \text{ kJ mol}^{-1}$.¹
- HOOI** Enthalpy values calculated using the isogyric reaction HOOH + IO → HO + HOOI with density functional theory (GP96PW91 level), employing reference enthalpies from this Table.¹

INO	Thermodynamic parameters from a third-law analysis of the equilibrium reaction $I + NO (+He) \leftrightarrow INO (+He)$. ⁴ Enthalpy of reaction obtained using CCSD(T) calculations at B3LYP geometries, with corrections for spin-orbit coupling, for $I + NO \rightarrow INO$, using Table reference values, leads to a 298 K enthalpy of 134.2 kJ mol ⁻¹ . ¹
INO₂	Thermodynamic parameters from a third-law analysis of the equilibrium reaction $I + NO_2 (+He) \leftrightarrow INO_2 (+He)$. ⁴
IOONO	Derived from CCSD(T) single-point calculations at B3LYP geometries for the interconversion of the two isomers. ³ The dissociation energy for IONO ₂ was also calculated to be 131.4 kJ mol ⁻¹ , leading to an enthalpy at 298K for that isomer of 24.8 kJ mol ⁻¹ , whereas a value of 37.5 kJ mol ⁻¹ has been selected for this Table.
IONO₂	The enthalpy values were derived from the average of the IO – NO ₂ bond dissociation energies calculated by Kaltsoyannis and Plane ¹ and by Marshall. ² See Table 3-1, note 32 for more details. The selected entropy value is also discussed in that note.

CHI	Enthalpy obtained using the computed enthalpy of a reaction of the type: $CH_2(^1A_1) + CH_3X + CH_3Y \rightarrow CXY(^1A_1) + 2CH_4$ at the QCISD(T)/6-311+G(3df,2p)//QCISD/6-311G(d,p) level of theory. Calculations also done at the G2 level. ⁸
CH₂I	Enthalpy value from <i>ab initio</i> calculations at the QCISD(T)/6-311+G(3df,2p) level of theory, utilizing an isodesmic reaction with methyl bromide. ⁷ A computational study of the $OH + CH_3I \rightarrow H_2O + CH_2I$ reaction at the DK-CCSD(T)/ANO-RCC-L(1)//MP2/ccpVTZ level of theory led to $\Delta_f H_{298}^\circ = 215.9$ kJ mol ⁻¹ and $\Delta_f H_0^\circ = 220.2$ kJ mol ⁻¹ . ⁶ These values provided the enthalpy difference utilized. A subsequent study on the reaction $OH + CH_2IBr \rightarrow HOBr + CH_2I$ led to $\Delta_f H_{298}^\circ = 218.4$ kJ mol ⁻¹ and $\Delta_f H_0^\circ = 223.3$ kJ mol ⁻¹ . ¹² Previous enthalpy value of 228.0±2.8 kJ mol ⁻¹ from <i>ab initio</i> calculations used to determine the entropies of the reactants and the transition state for $Br + CH_3I \rightarrow HBr + CH_2I$. Arrhenius parameters were then calculated by transition state theory. The kinetics of the reverse reactions were measured in a flow system. The enthalpy value was obtained from a second-law analysis. ⁹
CH₃I	Calculated from the dissociation of energy-selected CH_3I^+ and its adiabatic ionization energy. ¹⁰ Enthalpy from rotating combustion calorimetry is 14.4±1.4 kJ mol ⁻¹ . ² A review of the literature gave $\Delta_f H_{298}^\circ = 13.8 \pm 1.2$ kJ mol ⁻¹ and the enthalpy difference; the entropy is from ideal gas thermodynamic properties. ³
CI₂	Enthalpy obtained using the computed enthalpy of a reaction of the type: $CH_2(^1A_1) + CH_3X + CH_3Y \rightarrow CXY(^1A_1) + 2CH_4$ at the QCISD(T)/6-311+G(3df,2p)//QCISD/6-311G(d,p) level of theory. Calculations also done at the G2 level. ⁸
CHI₂	Enthalpy value from <i>ab initio</i> calculations at the QCISD(T)/6-311+G(3df,2p) level of theory, utilizing an isodesmic reaction with methyl bromide. ⁷ A computational study of the $OH + CH_3I \rightarrow HOI + CHI_2$ reaction at the CCSD(T)/ANO-RCC-Large//MP2/ccpVTZ level of theory led to $\Delta_f H_{298}^\circ = 309.2$ kJ mol ⁻¹ and $\Delta_f H_0^\circ = 298.9$ kJ mol ⁻¹ . ¹¹ These values provided the

enthalpy difference utilized. A computational study of the $\text{OH} + \text{CH}_2\text{I}_2 \rightarrow \text{H}_2\text{O} + \text{CHI}_2$ reaction at the DK-CCSD(T)/ANO-RCC-L(1)//MP2/ccpVTZ level of theory led to $\Delta_f H_{298}^\circ = 298.7 \text{ kJ mol}^{-1}$ and $\Delta_f H_0^\circ = 303.5 \text{ kJ mol}^{-1}$.⁶ Previous enthalpy value of $314.4 \pm 3.3 \text{ kJ mol}^{-1}$ from *ab initio* calculations used to determine the entropies of the reactants and the transition state for $\text{Br} + \text{CH}_2\text{I}_2 \rightarrow \text{HBr} + \text{CHI}_2$. Arrhenius parameters were then calculated by transition state theory. The kinetics of the reverse reactions were estimated. The enthalpy value was obtained from a second-law analysis.⁹

CH₂I₂ Enthalpy taken from a dissociative photoionization study of a series of dihalomethanes, normalized using the experimental enthalpy of dichloromethane.⁵ The reported value has been adjusted by $+0.4 \text{ kJ mol}^{-1}$ to agree with the present enthalpy for CH_2Cl_2 . Previous value of $119.5 \pm 2.2 \text{ kJ mol}^{-1}$ from rotating combustion calorimetry.² *Ab initio* calculations at the QCISD(T)/6-311+G(3df,2p) level of theory, utilizing an isodesmic reaction with methyl iodide, resulted in an enthalpy value of $108.1 \pm 6 \text{ kJ mol}^{-1}$.⁷ A review of the literature gave $\Delta_f H_{298}^\circ = 117.6 \pm 4.2 \text{ kJ mol}^{-1}$ and the enthalpy difference; the entropy is from ideal gas thermodynamic properties.⁴ In a more recent study, involving a TPEPICO determination of the heat of formation of 1,2- $\text{C}_2\text{H}_4\text{I}_2$, an analysis of the *ab initio* isodesmic reactions energies of four reactions led to a recommendation that the enthalpy values be reduced to $\Delta_f H_0^\circ = 123.1 \pm 2.0 \text{ kJ mol}^{-1}$ and $\Delta_f H_{298}^\circ = 113.5 \pm 2.0 \text{ kJ mol}^{-1}$.¹

CHI₃ *Ab initio* calculations at the QCISD(T)/6-311+G(3df,2p) level of theory, utilizing an isodesmic reaction with methyl iodide.⁷ Previous enthalpy value of $251.1 \pm 1.4 \text{ kJ mol}^{-1}$ from rotating combustion calorimetry.² A review of the literature gave $\Delta_f H_{298}^\circ = 210.9 \pm 4.2 \text{ kJ mol}^{-1}$ and the enthalpy difference; the entropy is from ideal gas thermodynamic properties.³

CI₃ Enthalpy value from *ab initio* calculations at the QCISD(T)/6-311+G(3df,2p) level of theory, utilizing an isodesmic reaction with methyl bromide.⁷ A computational study of the $\text{OH} + \text{CH}_3\text{I} \rightarrow \text{H}_2\text{O} + \text{CI}_3$ reaction at the CCSD(T)/ANO-RCC-Large//MP2/ccpVTZ level of theory led to $\Delta_f H_{298}^\circ = 387.4 \text{ kJ mol}^{-1}$ and $\Delta_f H_0^\circ = 384.4 \text{ kJ mol}^{-1}$.¹¹ These values provided the enthalpy difference utilized. Previous enthalpy value of $424.9 \pm 2.8 \text{ kJ mol}^{-1}$ from *ab initio* calculations used to determine the entropies of the reactants and the transition state for $\text{Br} + \text{CH}_2\text{I}_2 \rightarrow \text{HBr} + \text{CHI}_2$. Arrhenius parameters were then calculated by transition state theory. The kinetics of the reverse reactions were estimated. The enthalpy value was obtained from a second-law analysis.⁹ The uncertainty in the *ab initio* was suggested to be $\pm 9 \text{ kJ mol}^{-1}$. We have expanded that considerably due to these obvious disagreements.

CI₄ *Ab initio* calculations at the QCISD(T)/6-311+G(3df,2p) level of theory, utilizing an isodesmic reaction with methyl iodide.⁷ Previous enthalpy value of $474 \pm 13 \text{ kJ mol}^{-1}$ from rotating combustion calorimetry.² A review of the literature estimated $\Delta_f H_{298}^\circ = 268 \pm 4.2 \text{ kJ mol}^{-1}$ and the enthalpy difference; the entropy is from ideal gas thermodynamic properties.⁴ The uncertainty in the *ab initio* was suggested to be $\pm 12 \text{ kJ mol}^{-1}$. We have expanded that considerably due to these obvious disagreements.

CH₃C(O)I, acetyl iodide

Enthalpy value taken from review of Pedley.²

ICH₂CH₂OH

The enthalpy of formation of the liquid was determined by using rotating-bomb combustion calorimetry to be $\Delta_f H^\circ_{298}(\text{l}) = -207.3 \pm 0.7 \text{ kJ mol}^{-1}$. The molar enthalpy of vaporization was then determined by use of Calvert-drop microcalorimetry to be $\Delta_{\text{vap}} H^\circ_{298} = 57.03 \pm 0.20 \text{ kJ mol}^{-1}$.¹

Note 73: Compounds containing S, H and O

[Back to Table](#)

HSO	An enthalpy at 0 K determined to be -0.9 ± 0.7 kcal mol ⁻¹ (-3.8 ± 2.9 kJ mol ⁻¹) from crossed beam reactive scattering of O + H ₂ S. ² This was the value recommended in the previous Table. In a more recent study, the authors suggested that the lower bound to the uncertainty could be as much as -3 kcal mol ⁻¹ , but confirmed the upper bound as 0.7 kcal mol ⁻¹ . ³ A number of computational studies have converged on the significantly lower value presently recommended, which is taken from a study where the atomization energy was calculated by CCSD(T) extrapolated to the CBS limit, with geometry optimized at the CCSD(T)/aV(n+d)Z (n = D,T,Q,5) level. ⁷ This value was chosen for consistency with the other H _x O _y S _z species from the same work included in the table. In a more recent study, at the CCSDT(Q)/cc-pV(T+d)Z level, led to a value of $\Delta_f H_{298}^\circ = -22.6 \pm 2.3$ kJ mol ⁻¹ , in close agreement, and to the entropy value cited. ⁸
HOS	Atomization energy calculated by the CCSD(T) extrapolated to the CBS limit, with geometry optimized at the CCSD(T)/aV(n+d)Z (n = D,T,Q,5) level. ⁷ In a more recent study, at the CCSDT(Q)/cc-pV(T+d)Z level, led to a value of $\Delta_f H_{298}^\circ = -5.3 \pm 2.3$ kJ mol ⁻¹ , in close agreement, and to the entropy value cited. ⁸
HSO₂	Enthalpy obtained with DFT calculations on dissociation, atomization, and isodesmic reactions. ⁵ Value supported by a calculation of the H + SO ₂ dissociation asymptote. ¹ The latter study shows that HOSO is the more stable configuration, with HSO(O) as a local minimum.
HOSO	Atomization energy calculated by the CCSD(T) extrapolated to the CBS limit, with geometry optimized at the CCSD(T)/aV(n+d)Z (n = D,T,Q,5) level. ⁷ Lowest energy configuration is the <i>cis</i> isomer. Values for the <i>trans</i> isomer are $\Delta_f H_{298}^\circ = -56.2 \pm 1$ kcal mol ⁻¹ and $\Delta_f H_0^\circ = -55.1 \pm 1$ kcal mol ⁻¹ . Another CCSD(T) calculation to the CBS limit, with additional corrections, including correlation through the the CBSDT(Q) level, resulted in values for these isomers (identified as the <i>syn</i> and <i>anti</i> isomers) of $\Delta_f H_0^\circ = -58.0$ kcal mol ⁻¹ and $\Delta_f H_0^\circ = -55.7$ kcal mol ⁻¹ , respectively. ⁹
HSOO	Enthalpy for the reaction HOOSH + FOO → HOOF + HSOO at the CCSD(T)/CBS(Q,5) level of theory is 18.00 kcal mol ⁻¹ . Adjusted for the Table reference values, this gives the cited enthalpy of formation. ⁷ Lowest energy configuration is the <i>syn</i> isomer. Values for the <i>cis</i> isomer are $\Delta_f H_{298}^\circ = 29.9 \pm 1$ kcal mol ⁻¹ and $\Delta_f H_0^\circ = 31.3 \pm 1$ kcal mol ⁻¹ and for the <i>trans</i> isomer $\Delta_f H_{298}^\circ = 29.8 \pm 1$ kcal mol ⁻¹ and $\Delta_f H_0^\circ = 31.2 \pm 1$ kcal mol ⁻¹ .
HOSH	Atomization energy calculated by the CCSD(T) extrapolated to the CBS limit, with geometry optimized at the CCSD(T)/aV(n+d)Z (n = D,T,Q,5) level. $\Delta_f H_0^\circ = -26.5 \pm 1$ kcal mol ⁻¹ . ⁷ Lowest energy configuration is the <i>syn</i> isomer. Values for the <i>trans</i> isomer are $\Delta_f H_{298}^\circ = -24.3 \pm 1$ kcal mol ⁻¹ and $\Delta_f H_0^\circ = -22.7 \pm 1$ kcal mol ⁻¹ and for the <i>cis</i> isomer $\Delta_f H_{298}^\circ = -22.6 \pm 1$ kcal mol ⁻¹ and $\Delta_f H_0^\circ = -21.0 \pm 1$ kcal mol ⁻¹ .
HOOS	Enthalpy for the reaction HOOSH + FOO → HOOF + HOOS at the CCSD(T)/CBS(Q,5) level of theory is 5.14 kcal mol ⁻¹ . Adjusted for the Table reference values, this gives the cited enthalpy of formation, $\Delta_f H_0^\circ = 15.3 \pm 1.5$ kcal mol ⁻¹ . ⁷
HOOSH	Atomization energy calculated by the CCSD(T) extrapolated to the CBS limit, with geometry optimized at the CCSD(T)/aV(T+d)Z level. ⁷ Lowest energy configuration is the <i>syn</i> isomer.
HOSOH	Atomization energy calculated by the CCSD(T) extrapolated to the CBS limit, with geometry optimized at the CCSD(T)/aV(T+d)Z level. ⁷ Lowest energy configuration is the <i>syn</i> isomer.
HOSO₂	Thermodynamic parameters calculated at the CCSDT(Q)/cc-pV(T+d)Z level of theory. ⁸ A third-law analysis of equilibrium data for the reaction OH + SO ₂ ↔ HOSO ₂ (extrapolated from data over the temperature range 523 to 603 K) led to $\Delta_f H_{298}^\circ = 373 \pm 6$ kJ mol ⁻¹ , in good agreement with the computed value. ⁴
H₂SO₄	Taken from review of Dorofeeva et al. ⁶

- HOSS** Atomization energy calculated by the CCSD(T) extrapolated to the CBS limit, with geometry optimized at the CCSD(T)/aV(T+d)Z level.⁷ Lowest energy configuration is the *cis* isomer. Values for the *trans* isomer are $\Delta_f H_{298}^\circ = -13.6 \pm 1 \text{ kcal mol}^{-1}$ and $\Delta_f H_0^\circ = -12.7 \pm 1 \text{ kcal mol}^{-1}$.

CS Taken from review of Gurvich et al.⁵ The JANAF tables give $\Delta_f H_0^\circ = 277.1 \text{ kJ mol}^{-1}$, $\Delta_f H_{298}^\circ = 280.3 \text{ kJ mol}^{-1}$, and $S^\circ = 210.554 \text{ J mol}^{-1}$.²

CS₂ Taken from review of Gurvich et al.⁵ The JANAF tables give $\Delta_f H_0^\circ = 116.1 \text{ kJ mol}^{-1}$, $\Delta_f H_{298}^\circ = 116.9 \text{ kJ mol}^{-1}$, and $S^\circ = 237.977 \text{ J mol}^{-1}$.²

HCS Enthalpy $\Delta_f H_0^\circ = 71.7 \pm 2.0 \text{ kcal mol}^{-1}$ obtained from a photoionization study of CH₂S and CHS, obtained by sequential abstraction from CH₃SH.¹⁰ 298 K value from Berkowitz et al.¹

CH₂S Enthalpy $\Delta_f H_0^\circ = 28.3 \pm 2.0 \text{ kcal mol}^{-1}$ obtained from a photoionization study of CH₂S and CHS, obtained by sequential abstraction from CH₃SH.¹⁰ Integrated heat capacity from Berkowitz et al.¹

CH₃S Second- and third-law analysis were utilized to obtain an enthalpy of reaction of $-0.14 \pm 0.28 \text{ kcal mol}^{-1}$ for the reaction $\text{Br} + \text{CH}_3\text{SH} \leftrightarrow \text{HBr} + \text{CH}_3\text{S}$.⁷ Enthalpy calculated at the CCSD(T)/CBS level of theory is $29.7 \text{ kcal mol}^{-1}$.⁹ DFT calculations support an enthalpy value of $29.78 \pm 0.44 \text{ kcal mol}^{-1}$.³

CH₂SH A photoionization study¹⁰ leads to a recommended value for H-CH₂SH of 93.9±2.0 kcal mol⁻¹.¹ The enthalpy is from this and the present values for H and CH₃SH. Enthalpy values calculated at the CCSDT(Q)/cc-pV(T+d)Z level of theory give $\Delta_f H_0^\circ = 142.6$ kJ mol⁻¹ and $\Delta_f H_{298}^\circ = 143.4$ kJ mol⁻¹.⁶ The entropy value is also from this reference.

CH₃SH Enthalpy from Pedley⁸ entropy from Frenkel et al.⁴ Enthalpy calculated at the CCSD(T)/CBS level of theory is -5.31 kcal mol⁻¹.⁹

CS₂OH The temperature dependence of the equilibrium constant for the reaction OH + CS₂ ↔ CS₂OH resulted in a heat of reaction of -10.9±1.0 kcal mol⁻¹ and an entropy change of -24.0±4.4 cal K⁻¹ mol⁻¹.⁶

CH₂SO Thermodynamic parameters calculated at the CCSDT(Q)/cc-pV(T+d)Z level of theory.⁷ An enthalpy value of $\Delta_f H_{298}^\circ = -30$ kJ mol⁻¹ was derived from CBS-QB3 calculations on 10 reactions (one isodesmic).⁹

CH₂S(O)O Enthalpy derived from B3PW91 and OBS-QB3 calculations on 3 reactions (one isodesmic).¹¹

CH₃SO Derived from an reaction enthalpy of -22.88 kcal mol⁻¹ for the isodesmic reaction CH₃S + SO₃ → CH₃SO + SO₂ calculated at the CCSD(T) level extrapolated to the CBS limit.⁸

CH₃S(O)O Enthalpies of formation determined using five isodesmic reactions, with structures, vibrational frequencies, and rotational energies calculated at the B3LYP/6-311G(2p,d) level of theory, while the enthalpies were calculated at the CBS-QB3 level.⁴ Heat of atomization, dissociation, and three isodesmic reactions calculated at the G2(MP2) level of theory gave $\Delta_f H_{298}^\circ = -211$ kJ mol⁻¹, used in the previous Table.³ Enthalpy calculated at the CCSD(T)/CBS level of theory is -52.2 kcal mol⁻¹.⁸ A DFT estimate gives -56.3 kcal mol⁻¹.²

CH₃OSO Heat of atomization, dissociation, and two isodesmic reactions calculated at the G2(MP2) level of theory to yield the enthalpy of formation.³

CH₃SOO The equilibrium constant for the reaction $\text{CH}_3\text{S} + \text{O}_2 \leftrightarrow \text{CH}_3\text{SOO}$ was measured between 216 to 258 K and resulted in a bond strength of $11.7 \pm 0.9 \text{ kcal mol}^{-1}$.¹⁰

CH₂S(O)OH and CH₃S(O)OH

Enthalpies of formation determined using five isodesmic reactions, with structures, vibrational frequencies, and rotational energies calculated at the B3LYP/6-311G(2p,d) level of theory, while the enthalpies were calculated at the CBS-QB3 level.⁴

OCS Taken from review of Gurvich et al.⁵ The JANAF Tables give $\Delta_f H_0^\circ = -138.5 \text{ kJ mol}^{-1}$, $\Delta_f H_{298}^\circ = -138.4 \text{ kJ mol}^{-1}$, and $S^\circ = 231.581 \text{ J mol}^{-1}$.¹

NaBr Enthalpy and entropy values from the JANAF tables.¹

NaOH From an extensive evaluation from the Thermocenter of the RAS.³ The JANAF Tables give $\Delta_f H_{298}^\circ = -198 \pm 12 \text{ J mol}^{-1}$ and $\Delta_f H_0^\circ = -194 \pm 12 \text{ J mol}^{-1}$, and $S^\circ = 228.44 \text{ J mol}^{-1}$.¹ A calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit, leads to $\Delta_f H_{298}^\circ = -187.0 \pm 4 \text{ kJ mol}^{-1}$ and $\Delta_f H_0^\circ = -184.1 \pm 4 \text{ kJ mol}^{-1}$.⁶

NaO The enthalpy is from a calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit.⁶ Cited values are for the ²Π state. For the ²Σ⁺ state $\Delta_f H_{298}^\circ = 113.8 \pm 4 \text{ kJ mol}^{-1}$ and $\Delta_f H_0^\circ = 115.5 \pm 4 \text{ kJ mol}^{-1}$. The JANAF values are $\Delta_f H_{298}^\circ = 84 \pm 40 \text{ kJ mol}^{-1}$ and $\Delta_f H_0^\circ = 85 \pm 40 \text{ kJ mol}^{-1}$, and the cited entropy.¹ The Pedley and Marshall review

gives $\Delta_f H_{298}^\circ = 100 \pm 17 \text{ kJ mol}^{-1}$.⁵ The Lamoreaux and Hildenbrand review gives $\Delta_f H_{298}^\circ = 104.6 \pm 4.2 \text{ kJ mol}^{-1}$ and $S^\circ = 228.48 \text{ J mol}^{-1}$.⁴

NaO₂ and NaO₃

Atomization energy calculated by the CCSD(T) extrapolated to the CBS limit.⁶

Na₂O Atomization energy calculated by the CCSD(T) extrapolated to the CBS limit.⁶ The Lamoreaux and Hildenbrand review gives $\Delta_f H_{298}^\circ = -31.8 \pm 3.7 \text{ kJ mol}^{-1}$ and the cited entropy.⁴

K CODATA Key Value.² The Lamoreaux and Hildenbrand review gives $\Delta_f H_{298}^\circ = 89.2 \pm 0.2 \text{ kJ mol}^{-1}$ and the cited entropy.⁴

KH Enthalpy and entropy values from the JANAF tables.¹ A calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit, leads to $\Delta_f H_{298}^\circ = 132.2 \pm 4 \text{ kJ mol}^{-1}$ and $\Delta_f H_0^\circ = 134.7 \pm 4 \text{ kJ mol}^{-1}$.⁶

KF Enthalpy and entropy values from the JANAF tables.¹ A calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit, leads to $\Delta_f H_{298}^\circ = -326.8 \pm 4 \text{ kJ mol}^{-1}$ and $\Delta_f H_0^\circ = -324.7 \pm 4 \text{ kJ mol}^{-1}$.⁶

KCl Enthalpy and entropy values from the JANAF tables.¹ A calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit, leads to $\Delta_f H_{298}^\circ = -215.5 \pm 4 \text{ kJ mol}^{-1}$ and $\Delta_f H_0^\circ = -213.4 \pm 4 \text{ kJ mol}^{-1}$.⁶

KBr Enthalpy and entropy values from the JANAF tables.¹

KOH From an extensive evaluation from the Thermocenter of the RAS.³ The JANAF Tables give $\Delta_f H_{298}^\circ = -233 \pm 12 \text{ J mol}^{-1}$ and $\Delta_f H_0^\circ = -228 \pm 12 \text{ J mol}^{-1}$, and $S^\circ = 236.379 \pm 1.31 \text{ J mol}^{-1}$.¹ A calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit, leads to $\Delta_f H_{298}^\circ = -221.8 \pm 4 \text{ kJ mol}^{-1}$ and $\Delta_f H_0^\circ = -218.0 \pm 4 \text{ kJ mol}^{-1}$.⁶

KO The enthalpy is from a calculation of the atomization energy at the CCSD(T) level, extrapolated to the CBS limit.⁶ Cited values are for the ²II state. For the ²Σ⁺ state $\Delta_f H_{298}^\circ = 59.8 \pm 4 \text{ kJ mol}^{-1}$ and $\Delta_f H_0^\circ = 61.9 \pm 4 \text{ kJ mol}^{-1}$. The JANAF values are $\Delta_f H_{298}^\circ = 71 \pm 40 \text{ kJ mol}^{-1}$ and $\Delta_f H_0^\circ = 73 \pm 40 \text{ kJ mol}^{-1}$, and the cited entropy.¹ The Pedley and Marshall review gives $\Delta_f H_{298}^\circ = 61 \pm 21 \text{ kJ mol}^{-1}$.⁵ The Lamoreaux and Hildenbrand review gives $\Delta_f H_{298}^\circ = 59.9 \pm 4.2 \text{ kJ mol}^{-1}$ and $S^\circ = 237.88 \text{ J mol}^{-1}$.⁴

KO₂ and KO₃

Atomization energy calculated by the CCSD(T) extrapolated to the CBS limit.⁶

- K₂O** Atomization energy calculated by the CCSD(T) extrapolated to the CBS limit.⁶ The Lamoreaux and Hildenbrand review gives $\Delta_f H_{298}^\circ = -58.61 \pm 2.2 \text{ kJ mol}^{-1}$ and the cited entropy.⁴

Note 84: *Compounds containing Hg and H or O*

[Back to Table](#)

- Hg⁰** CODATA key values,² with the 0 K value calculated in JANAF.¹ The NBS Tables give $\Delta_f H^\circ(298 \text{ K}) = 61.32 \text{ kJ mol}^{-1}$ and $S^\circ = 179.03 \text{ J mol}^{-1} \text{ K}^{-1}$.¹¹ The review of Hepler and Olofsson accept the NBS value, but also discuss some more recent vapor pressure measurements.⁶
- HgH** Chosen values from the JANAF Table,¹ based on results reported by Herzberg.⁷ Also selected by Hepler and Olofsson.⁶ The NBS Tables give $\Delta_f H^\circ(298 \text{ K}) = 239.32 \text{ kJ mol}^{-1}$ and $S^\circ = 219.49 \text{ J mol}^{-1} \text{ K}^{-1}$.¹¹ A calculation using NESC/CCSD(T) in combination with triple-zeta basis sets, gave BDE = 38.5 kJ mol⁻¹, which leads to $\Delta_f H^\circ(0 \text{ K}) = 238.76 \text{ kJ mol}^{-1}$.³
- HgH₂** The cited enthalpy values are an average of those calculated for the atomization energy and for the bond-dissociation reaction, $\text{HgH}_2 \rightarrow \text{HgH} + \text{H}$, both done at the NESC/B3LYP level of theory.³
- HgO** The selected enthalpy of formation is derived from computational determinations of the bond dissociation energy. Dissociation from both the ¹Σ⁺ (to Hg¹S and O¹D) and ³Π (to Hg¹S and O³P) states of HgO have been reported, with some disagreement about which is the ground state. From a relativistically-corrected MP4/CCSD(T) calculation, $D_0 = 9.2 \text{ kJ mol}^{-1}$ from a triplet ground state by Filatov and Cremer.⁴ A subsequent study from the same group, adding the normalized elimination of the small component technique to improve the treatment of scalar relativistic effects, found the ³Π state 5.4 kJ mol⁻¹ lower than the ¹Σ⁺ state, and also calculated BDEs of 16.1 kJ mol⁻¹ along the triplet surface and 202.9 kJ mol⁻¹ along the singlet surface, both adjusted to 298 K.³ At 0 K, the calculated triplet BDE was 14.6 kJ mol⁻¹. In contrast, a MRCI + Q/CBS level calculation by Peterson et al.⁸ found a singlet ground state and computed a BDE of 203.3 kJ mol⁻¹ at 0 K. This result is in agreement with earlier calculations from the same laboratory which resulted in a BDE to ground-state atoms of 17 and 19.1 kJ mol⁻¹.^{9,10}
- There has been an experimental determination of the dissociation energy of HgO by using high-temperature mass spectrometry.⁵ In strong disagreement with the computational studies, a value of $222 \pm 33 \text{ kJ mol}^{-1}$ was determined. Filatov and Cremer⁴ have made a compelling case that the species detected in the mass spectrometer being a dimer, either or both HgO₂Hg and OHg₂O. There is clearly a great need for additional experimental work on HgO, but at this point, we accept the theoretical argument.

[Back to Table](#)

HgF, HgCl, HgBr, HgI, HgF₂, HgCl₂, HgBr₂, HgI₂

At this time, we accept the JANAF values.³ More recent experimental and computational results scatter around these values, with no clear pattern. These are discussed below.

HgF The JANAF enthalpy value has a stated uncertainty of $\pm 50 \text{ kJ mol}^{-1}$. We have reduced this to $\pm 20 \text{ kJ mol}^{-1}$ in light of the additional results discussed below. The JANAF enthalpy value leads to a BDE of $134 \pm 20 \text{ kJ mol}^{-1}$ at 0 K. A MP4/CCSD(T) calculation, including a normalized elimination of the small component (NESC) technique to improve the treatment of scalar relativistic effects, resulted in a BDE of 129 kJ mol^{-1} ,⁴ while another CCSD(T) study led to values of 137 and 115 kJ mol^{-1} with the CRENBL and AVTZ-PP relativistic effective core potentials, respectively.⁶

HgCl The JANAF enthalpy value leads to a BDE of $102 \pm 10 \text{ kJ mol}^{-1}$ at 0 K. A reanalysis of the spectral data suggested a value of $\sim 106 \text{ kJ mol}^{-1}$.⁹ A more recent spectral study led to an upper limit on the BDE of 98 kJ mol^{-1} ,⁸ although an analysis of these data by using empirical potential energy functions led to $\text{BDE} = 107 \text{ kJ mol}^{-1}$.² Computational results tend to be lower: A CCSD(T)/CBS with relativistic pseudopotentials, corrected for spin-orbit coupling, gave a BDE of 96 kJ mol^{-1} ,⁷ whereas a MP4/CCSD(T) calculation, including a normalized elimination of the small component (NESC) technique to improve the treatment of scalar relativistic effects, resulted in a BDE of 89.5 kJ mol^{-1} .⁴ Another CCSD(T) study led to values of 94 and 78 kJ mol^{-1} with the CRENBL and AVTZ-PP relativistic effective core potentials, respectively.⁶

HgBr The JANAF enthalpy value has a stated uncertainty of $\pm 38 \text{ kJ mol}^{-1}$. We have reduced this to $\pm 10 \text{ kJ mol}^{-1}$ in light of the additional results discussed below. The JANAF enthalpy value leads to a BDE of $67 \pm 10 \text{ kJ mol}^{-1}$ at 0 K. A reanalysis of the spectral data suggested a value

of $\sim 72 \text{ kJ mol}^{-1}$.⁹ A more recent spectral study led to a BDE of 66.1 kJ mol^{-1} ,⁸ although an analysis of these data by using empirical potential energy functions led to $\text{BDE} = 61.75 \text{ kJ mol}^{-1}$.² A CCSD(T)/CBS with relativistic pseudopotentials, corrected for spin-orbit coupling, gave a BDE of 68 kJ mol^{-1} ,⁷ whereas a MP4/CCSD(T) calculation, including a normalized elimination of the small component (NESC) technique to improve the treatment of scalar relativistic effects, resulted in a BDE of 60 kJ mol^{-1} .⁴ Another CCSD(T) study led to values of 21 and 59 kJ mol^{-1} with the CRENBL and AVTZ-PP relativistic effective core potentials, respectively.⁶ A slightly different BDE of 66.3 kJ mol^{-1} was used in the analysis of the equilibrium constant data in Table 3-1, Note 33.

HgI The JANAF enthalpy value leads to a BDE of $32.9 \pm 5 \text{ kJ mol}^{-1}$ at 0 K. A reanalysis of the spectral data suggested a value of 37.3 kJ mol^{-1} .⁹ A more recent spectral study led to a BDE of 33.5 kJ mol^{-1} ,⁸ although an analysis of these data by using empirical potential energy functions led to $\text{BDE} = 37.3 \text{ kJ mol}^{-1}$.² A CCSD(T)/CBS calculation with relativistic pseudopotentials, corrected for spin-orbit coupling,⁷ gave a BDE of 36 kJ mol^{-1} whereas a MP4/CCSD(T) calculation, including the normalized elimination of the small component (NESC) technique to improve the treatment of scalar relativistic effects, resulted in a BDE of 46 kJ mol^{-1} .⁴ Another CCSD(T) study led to values of 15 and 38.5 kJ mol^{-1} with the CRENBL and AVTZ-PP relativistic effective core potentials, respectively.⁶

HgF₂ In this case, the values listed in the JANAF Table are estimated. Enthalpy values have been calculated for the atomization energy and for the bond-dissociation reaction, $\text{HgF}_2 \rightarrow \text{HgF} + \text{F}$ at the NESC/B3LYP level of theory, leading to average values of $\Delta_f H^0(298 \text{ K}) = -288 \text{ kJ mol}^{-1}$ and $\Delta_f H^0(0 \text{ K}) = -296 \text{ kJ mol}^{-1}$.⁴ A CCSD(T) study led to $\Delta_f H^0(0 \text{ K}) = -302$ and -285 kJ mol^{-1} with the CRENBL and AVTZ-PP relativistic effective core potentials, respectively.⁶

HgCl₂ The values listed in the JANAF Table are based on a third-law analysis. A CCSD(T) calculation utilizing small-core relativistic effective core potentials for the reaction $\text{Hg} + \text{Cl}_2 \rightarrow \text{HgCl}_2$ led to $\Delta_f H^0(0 \text{ K}) = -139 \text{ kJ mol}^{-1}$.¹ Another CCSD(T) study led to $\Delta_f H^0(0 \text{ K}) = -134$ and -122 kJ mol^{-1} with the CRENBL and AVTZ-PP relativistic effective core potentials, respectively.⁶ A third CCSD(T) study, with the ECP60MDF relativistic core potential and B3LYP/aVTZ structures gave -135 kJ mol^{-1} .⁵

HgBr₂ The values listed in the JANAF Table are based on a third-law analysis. A CCSD(T) calculation utilizing small-core relativistic effective core potentials for the reaction $\text{Hg} + \text{Br}_2 \rightarrow \text{HgBr}_2$ led to $\Delta_f H^0(0 \text{ K}) = -67 \text{ kJ mol}^{-1}$.¹ Another CCSD(T) study led to $\Delta_f H^0(0 \text{ K}) = -42$ and -34 kJ mol^{-1} with the CRENBL and AVTZ-PP relativistic effective core potentials, respectively.⁶ A third CCSD(T) study, with the ECP60MDF relativistic core potential and B3LYP/aVTZ structures gave $\Delta_f H^0(0 \text{ K}) = -81 \text{ kJ mol}^{-1}$.⁵

HgI₂ The values listed in the JANAF Table are based on a third-law analysis. A calculated enthalpy for the reaction $\text{HgI}_2 \rightarrow \text{Hg} + \text{I}_2$ at the CCSD(T)/CBS limit with corrections for core-valence correlation, spin-orbit coupling, Lamb shift, and scalar relativity leads to the value $\Delta_f H^0(0 \text{ K}) = -16 \text{ kJ mol}^{-1}$.⁷ Another CCSD(T) study led to $\Delta_f H^0(0 \text{ K}) = 9.6$ and 20 kJ mol^{-1} with the CRENBL and AVTZ-PP relativistic effective core potentials, respectively.⁶
