ABSTRACT

This is the eighteenth in a series of evaluated sets of rate constants, photochemical cross sections, heterogeneous parameters, and thermochemical parameters compiled by the NASA Panel for Data Evaluation.

The data are used primarily to model stratospheric and upper tropospheric processes, with particular emphasis on the ozone layer and its possible perturbation by anthropogenic and natural phenomena.

The evaluation is available in electronic form from the following Internet URL:

<http://jpldataeval.jpl.nasa.gov/>

This evaluation should be cited using the following format:

INTRODUCTION

This compilation of kinetic and photochemical data is the 18th evaluation prepared by the NASA Panel for Data Evaluation. The Panel was established in 1977 by the NASA Upper Atmosphere Research Program Office for the purpose of providing a critical tabulation of the latest kinetic and photochemical data for use by modelers in computer simulations of atmospheric chemistry. Table I-1 lists this publication's editions:

Table I-1: Editions of this Publication

	Edition	Reference
1	NASA RP 1010, Chapter 1	Hudson et al. ¹
2	JPL Publication 79-27	DeMore et al. ¹²
3	NASA RP 1049, Chapter 1	Hudson and Reed ²
4	JPL Publication 81-3	DeMore et al. ¹⁰
5	JPL Publication 82-57	DeMore et al. ⁸

In addition to the current edition, several previous editions are available for download from <http://jpldataeval.jpl.nasa.gov/>. This document is not available in printed form.

Contributions to the evaluation from past panel members are gratefully acknowledged. Past panel members and years of contribution are listed in Table I-2.

Table I-2: Past Panel Members

Panel Member	Years of Contribution
D. M. Golden	1977–2011
M. J. Molina	1977–2006
W. B. DeMore	1977–2000
R. F. Hampson	1977–2000
R. T. Watson	1977–1985
J. J. Margitan	1977–1985
L. J. Stief	1977–1981
D. Garvin	1977
C. J. Howard	1979–1997
F. Kaufman	1979–1981
A. R. Ravishankara	1982–2006
G. K. Moortgat	2000–2011
R. R. Friedl	2000–2011
B. J. Finlayson-Pitts	2002–2006

Current panel members, and their major responsibilities for the current evaluation are listed in Table I-3.

Table I-3: Panel Members and their Major Responsibilities for the Current Evaluation

Panel Member	Responsibility
J. B. Burkholder, co-Chair	Editorial review O _x , O(¹ D), HO _x reactions Photochemistry References
S. P. Sander, co-Chair	Editorial review
J. Abbatt	Heterogeneous chemistry
J. R. Barker	Three-body reactions Equilibrium constants
R. E. Huie	Aqueous chemistry Henry's Law coefficients Thermodynamic parameters
C. E. Kolb	Heterogeneous chemistry Na chemistry
M. J. Kurylo	Halocarbon reactions
V. L. Orkin	Halocarbon reactions
D. M. Wilmouth	Editorial review
P. H. Wine	SO _x reactions Isoprene chemistry Chemistry of isoprene degradation products

As shown above, each Panel member concentrates their efforts on a given area or type of data. Nevertheless, the Panel's final recommendations represent a consensus of the entire Panel. Each member reviews the basis for all recommendations and is cognizant of the final decision in every case.

Address communications regarding particular reactions to the appropriate panel member:

I.1 Basis of the Recommendations

In so far as possible, all recommendations are based on laboratory measurements. In order to provide recommendations that are as up-to-date as possible, preprints and written private communications are accepted, but only when it is expected that they will appear as published journal articles. Recommendations are not adjusted to fit observations of atmospheric concentrations. The Panel considers the question of consistency of data with expectations based on the theory of reaction kinetics, and when a discrepancy appears to exist this fact is pointed out in the accompanying note. The major use of theoretical extrapolation of data is in connection with three-body reactions, in which the required pressure or temperature dependence is sometimes unavailable from laboratory measurements, and can be estimated by use of appropriate theoretical treatment. In some cases where no experimental data are available, the Panel may provide estimates of rate constant parameters based on analogy to similar reactions for which data are available.

I.2 Scope of the Evaluation

In the past (releases 1-12 of this evaluation), it was the practice of the Panel to reevaluate the entire set of reactions with individual Panel members taking responsibility for specific chemical families or processes. In recent years, the upper troposphere and lower stratosphere (UT/LS) have become the primary areas of focus for model calculations and atmospheric measurements related to studies of ozone depletion and climate change. Because the UT/LS is a region of relatively high chemical and dynamical complexity, a different approach was adopted for subsequent releases of the evaluation. Specifically, the entire reaction set of the data evaluation is no longer re-evaluated for each release. Instead, specific subsets are chosen for re-evaluation, with several Panel members working to develop recommendations for a given area. This approach makes it possible to treat each subset in greater depth, to examine the consistency of the recommended parameters within a given chemical family, and to expand the scope of the evaluation to new areas. It is the aim of the Panel to consider the entire set of kinetics, photochemical, and thermodynamic parameters every three review cycles. Each release of the evaluation will contain not only the new evaluations, but also recommendations for every process that has been considered in the past. In this way, the tables for each release constitute a complete set of recommendations.

It is recognized that important new laboratory data may be published that lie outside the specific subset chosen for re-evaluation. In order to ensure that these important data receive prompt consideration, each evaluation will also have a “special topics” category. Feedback from the atmospheric modeling community is solicited in the selection of reactions for this category.

For the current evaluation, the specific subsets include the following:

- Reactions of O(¹D)
- Reactions of OH with halocarbons
- Reactions of sulfur compounds
- Initial steps in isoprene oxidation
- Photochemistry of O₃, organic compounds and halogen oxides
- Heterogeneous processes on liquid water, water ice, alumina and solid alkali halide salts
- Gas-liquid solubility (Henry’s Law Constants)
- Thermodynamic parameters (entropy and enthalpy of formation)

I.3 Format of the Evaluation

Changes or additions to the data tables are indicated by shading. A new entry is completely shaded, whereas a changed entry is shaded only where it has changed. In some

cases, only the note has been changed, in which case the corresponding note number in the table is shaded.

The notes associated with each bimolecular reaction are an essential component of the evaluation. Thus, the reader is strongly encouraged to consult these notes as they contain important kinetic / numerical information that could not conveniently be included in the Table of recommended parameters. In several cases the note for a bimolecular reaction contains a three-parameter Arrhenius expression that better represents the accepted experimental data over a much broader temperature range than the two-parameter Arrhenius expression given in the table, whose applicability is limited to a narrower temperature range as indicated in the note. Table entries for some reactions provide rate constant recommendations for individual reaction channels. In these cases the recommendation for the total reaction rate constant is given separately in the note.

Every note in Tables 1-3 and in the photochemistry section includes a “time stamp” indicating the latest revision date for changes in the recommendation or in the note as well as the date of the most recent evaluation. In some cases, a reaction may have undergone a complete re-evaluation without changes in the recommendations (i.e., Table entries) or in the note. For such reactions, the date of the evaluation will be updated even though the re-evaluation did not result in any changes.

I.4 Computer Access

This document is available online in the form of individual chapters and as a complete document in Adobe PDF (Portable Data File) format. Files may be downloaded from <http://jpldataeval.jpl.nasa.gov/>. This document is not available in printed form.

The tables of recommended photochemical cross sections from this evaluation can be downloaded from the spectral atlas of the Max-Planck Institute for Chemistry at: http://satellite.mpic.de/spectral_atlas.

To receive email notification concerning releases of new publications and errata, a mailing list is available. To subscribe, send a blank message to sympa@list.jpl.nasa.gov with “subscribe jpl-dataeval” (without quotes) in the subject line.

For more information, contact Stanley Sander (Stanley.Sander@jpl.nasa.gov) or James Burkholder (James.B.Burkholder@noaa.gov).

I.5 Data Formats

In Table 1 (Rate Constants for Bimolecular Reactions) the reactions are grouped into the classes O_x, HO_x, NO_x, Organic Compounds, FO_x, ClO_x, BrO_x, IO_x, SO_x, and Metal Reactions. The data in Table 2 (Rate Constants for Association Reactions) are presented in the same order as the bimolecular reactions. The presentation of photochemical cross section data follows the same sequence.

I.6 Units

Rate constants are given in units of concentration expressed as molecules per cubic centimeter and time in seconds. That is, for first-, second-, and third-order reactions, units of k are s⁻¹, cm³ molecule⁻¹ s⁻¹, and cm⁶ molecule⁻² s⁻¹, respectively. Absorption cross sections are expressed as cm² molecule⁻¹, base e.

I.7 Noteworthy Changes in this Evaluation

The layout of the evaluation has been revised to include with each note the full citations for the references cited within that note. In addition, complete section bibliographies are

included at the end of each section and a Master Bibliography for the entire document is given in Section 7. Hyperlinks have been added to Table 4-1 of the Photochemistry section, Henry's Law section, and the Thermochemistry section to facilitate improved navigation within these sections.

1.7.1 Bimolecular Reactions (Section 1)

A comprehensive review of the O(¹D) reactions was included in this evaluation. The O(¹D) reaction entries and recommendations were expanded to include the total rate coefficient (i.e., O(¹D) loss) and the product branching ratios and estimated uncertainties, where experimental data were available. The basis for the branching ratio recommendations is provided in the note for each reaction. The current recommendations build on those given in the SPARC (2013) Lifetime Report¹³ for a sub-set of the molecules included in Table 1. New entries include HCN, CH₃CN, CH₃Cl, CH₃CCl₃, 1,2-*c*-C₄Cl₂F₆ (*E,Z*), CF₃CHFCF₃ (HFC-227ea), and CHF₂CH₂CF₃ (HFC-245fa).

A comprehensive review of the FO_x, ClO_x, and BrO_x reactions in subsections E1, F1, and G1 respectively was conducted for this evaluation with particular emphasis on the reactions of OH and Cl with hydrocarbons and halocarbons (including halogenated ethers, alcohols, etc.). For several of these reactions, recommendation updates were made for consistency with the 2013 SPARC Lifetime Report.¹³ In a few cases, the SPARC recommendations themselves were updated. Many of the recommendations are based (at least in part) on relative rate investigations in which the derivation of the target rate constant was based on the rate constant for one or more reference reactions. In cases where significant revisions were made in the recommended rate parameters for reactions that were used as references in relative rate studies, the effect on other reaction recommendations was tracked and appropriate revisions were made. For all reactions, careful attention was paid to providing the most realistic values for the uncertainty parameters, *f*(298 K) and *g*, given in Table 1. More details regarding the selection of these values are provided to the introduction to Section 1.

Subsection H1 on IO_x reactions was not a focus of this evaluation but one important reaction, IO + HO₂, has been re-evaluated.

The section on sulfur reactions includes eleven reactions that had not been evaluated previously: five reactions related to the atmospheric oxidation of methyl ethyl sulfide (CH₃SC₂H₅), reactions of the three simplest Criegee intermediates (CH₂OO, *syn*-CH₃CHOO, and *anti*-CH₃CHOO) with SO₂, the reaction of OH with methane sulfonic acid (MSA, CH₃SO₃H), and reactions of CH₃S radicals with CO and Br₂. In addition, recommendations and notes for the OH + OCS and S + O₂ reactions have been updated, as have notes for nine other sulfur reactions.

Evaluations for reactions of O₃, OH, NO₃, Cl, and Br with isoprene were included in Evaluation 17 for the first time. Recommendations for all five of these isoprene reactions are updated and reactions of the first generation isoprene oxidation products methyl vinyl ketone (MVK, CH₃C(O)CH=CH₂) and methacrolein (CH₂=C(CH₃)CHO) with O₃, OH, NO₃, Cl, and Br are evaluated for the first time. Also evaluated for the first time are reactions of the three simplest Criegee intermediates with water and water dimer. In addition, notes for reactions of OH with HCN and CH₃CN are updated to include available information about reaction mechanisms.

1.7.2 Termolecular Reactions (Section 2)

Several new reactions have been added to Table 2. These include the self-reaction of CH₂OO radicals (the simplest Criegee intermediate) and the reaction of CH₂I radicals with O₂ (which produces the CH₂OO and other products). In addition, the adduct-forming reactions of OH + olefins has received special attention. The reaction of OH with ethylene has been re-

evaluated and new evaluations are reported for the reactions of OH with propene, 1-butene, isobutene, and *cis*- and *trans*-2-butene. New entries also appear for $\text{CH}_3\text{S} + \text{O}_2$, for $\text{Hg} + \text{Br}$, and for $\text{Br} + \text{isoprene}$ and 1,3-butadiene. Several entries have been up-dated, including $\text{OH} + \text{NO}_2$, $\text{HO}_2 + \text{NO}_2$, $\text{NO}_2 + \text{NO}_3$, $\text{ClO} + \text{ClO}$, and $\text{BrO} + \text{NO}_2$.

1.7.3 Equilibrium Constants (Section 3)

Several new entries have been added to Table 3. These include the equilibrium constants for formation of the water dimer; for HO_2 complexes with formaldehyde, acetaldehyde, and acetone; for complexes of Br with isoprene and 1,3-butadiene; for $\text{CH}_3\text{S} + \text{O}_2$; for $\text{IO} + \text{NO}_2$ and for $\text{Hg} + \text{Br}$. Previous entries for $\text{NO}_2 + \text{NO}_3$ and for $\text{ClO} + \text{ClO}$ have been updated.

1.7.4 Photochemical Data (Section 4)

Notes have been revised and updated as indicated in Table 4-1. The previously included table of uncertainty (absorption cross section $\times$ photolysis quantum yield) for a number of key species has been deleted. The recommended uncertainty estimates for the absorption cross sections and photolysis quantum yields are now included separately within the notes. (However, not all molecules include uncertainty estimates.) Absorption cross section uncertainty factors are primarily based on the wavelength regions most critical to atmospheric photolysis. New entries have been added in the Organic, FO_x , ClO_x , and IO_x Photochemistry sub-sections. On the basis of a recent study, the recommendation for the ClOOC UV absorption cross sections, which are important for modeling polar stratospheric ozone depletion, was revised.

1.7.5 Heterogeneous Chemistry (Section 5)

In this evaluation, selected uptake processes occurring on alumina, liquid water, water ice, solid salt, and salt solutions have been added or updated. The compilation of Henry's law parameters for pure water has been extended to include a large number of additional oxygenated organic, halo-organic, organic amine, and organic sulfide compounds. The compilation of Henry's law parameters in sulfuric acid solutions have been added or updated for a few oxygenated organics. A new compilation of Henry's Law constants for uptake into seawater (or into NaCl solutions at about 35‰ salinity) has been added, with a particular emphasis on halogenated organics.

1.7.6 Thermodynamic Parameters (Section 6)

The Table of Thermodynamic Properties has been further expanded to almost 800 species, now including mercury compounds. The additions include mercury-halogen, mercury-halogen-oxygen, and mercury-halogen-nitrogen oxide species, which may be important for predicting which reactions can be of significance in the atmosphere. Since all of these entries are new, they have not been shaded to indicate a change or insertion. The Table has been divided into 90 groups, each linked to the notes for those species. The references for each group are at the end of the notes for that group. In addition, there is a list of groups at the beginning of the Table, with links to the individual groups.

1.7.7 Bibliography – Master (Section 7)

In addition to the bibliographies included at the end of each section, all references cited within the evaluation (~5000) are summarized in this section. References have been updated to include full titles and doi's for most post-2000 publications. Doi's for older references are provided in some cases and will be updated in future evaluations.

I.8 Acknowledgements

The Panel wishes to acknowledge the technical support provided by Liz Juvera and Samantha Ozyildirim. Financial support from the NASA Upper Atmosphere Research and Tropospheric Chemistry Programs is gratefully acknowledged.

1.1 Introduction

In Table 1 (Rate Constants for Bimolecular Reactions) the evaluated reactions are grouped into the classes O_x, O(¹D), Singlet O₂, HO_x, NO_x, Organic Compounds, FO_x, ClO_x, BrO_x, IO_x, SO_x, and Metals. Some of the reactions in Table 1 are actually more complex than simple two-body, bimolecular, reactions. To explain the pressure and temperature dependences occasionally measured in reactions of this type, it is necessary to consider the bimolecular class of reactions in terms of two subcategories, direct (concerted) and indirect (nonconcerted) reactions.

A direct, or concerted, bimolecular reaction is one in which the reactants A and B proceed to products C and D without the intermediate formation of an AB adduct that has appreciable bonding, i.e., there is no bound intermediate; only the transition state [AB][#] lies between reactants and products.

The reaction of OH with CH₄ forming H₂O + CH₃ is an example of a reaction of this class.

The rate constants for these reactions can, in general, be reasonably well represented by the Arrhenius expression

$$k(T) = A \times \exp(-E/RT)$$

over the temperature range of atmospheric interest. Very useful correlations between the expected structure of the transition state [AB][#] and the Arrhenius A-factor of the reaction rate constant can be made, especially in reactions that are constrained to follow a well-defined approach of the two reactants in order to minimize energy requirements in the making and breaking of bonds. The recommended parameters, A and E/R, are given in Table 1 as discussed below and the temperature range associated with their recommended use is given in the corresponding reaction note (e.g. "below 400 K"). Rate constants for reactions of this type are not pressure dependent.

However, even for this class of reactions, deviation in the temperature dependence from the simple Arrhenius expression mentioned above may be apparent over the full range of the experimental data considered in the evaluation, and even over the more limited temperature range used to derive the Arrhenius expression recommendation. Deviation from Arrhenius behavior is typically exhibited as curvature in the Arrhenius plot - a concave upward curvature in ln(k(T)) versus 1/T. There are several possible factors that may contribute to this curvature such as multiple reaction channels, the existence of reactant conformers, tunneling, and others. In cases where curvature was experimentally resolved, the reaction note emphasizes the temperature range over which the Arrhenius parameters given in Table 1 are applicable and also provides a recommended three-parameter expression

$$k(T) = A \times (T/298)^n \times \exp(-E/RT)$$

where n is a fit parameter, that better represents the overall temperature dependence.

The indirect or nonconcerted class of bimolecular reactions is characterized by a more complex reaction path involving a potential well between reactants and products, leading to a bound adduct (or reaction complex) formed between the reactants A and B:

The intermediate [AB]^{*} is different from the transition state [AB][#], in that its lifetime substantially exceeds the characteristic time of intermolecular vibrations and, thus, it is considered a bound molecule. Of course, transition states are involved in all reactions, both forward and backward, but are not explicitly shown in the equation above. An example of a reaction of this class is ClO + NO, which normally produces Cl + NO₂. Reactions of the nonconcerted type can have more complex temperature dependences and can exhibit a pressure dependence if the lifetime of [AB]^{*} is comparable to the rate of its collisional deactivation. This arises because the relative rate at which a complex [AB]^{*} decomposes to products C + D or back to reactants A + B is a sensitive function of its internal energy. Thus, in reactions of this type, the distinction between the bimolecular and termolecular classification becomes less meaningful, and it is especially necessary to study such reactions under the temperature and pressure conditions in which they are to be used in model calculations, or, alternatively, to develop reliable theoretical bases for extrapolation of the experimental data. In several cases where sufficient data exist, reactions of this type are treated in Section 2 and included in the corresponding table for termolecular reactions.

As mentioned above, the recommended rate constant tabulation for bimolecular reactions (Table 1) is given in Arrhenius form, $k(T) = A \times \exp(-E/RT)$, and contains the following information:

1. Reaction stoichiometry and products (if known).

2. Arrhenius A-factor: **A**
3. Recommended temperature dependence (“activation temperature”): **E/R**
4. Recommended rate constant at 298 K: **k(298 K)**
5. Rate constant uncertainty factor at 298 K: **f(298 K)** (see below)
6. A parameter used to calculate the rate constant uncertainty at temperatures other than 298 K: **g** (see below)
7. Index number for a detailed note containing references to the literature, the basis of recommendation and, in several cases, alternative methods to calculate the rate constant.

For a few reactions, the recommendations for A, E/R and k(298 K) are italicized in blue font. These represent estimates by the Panel in cases where there are either no literature data, where the existing data are judged to be of insufficient quality to base a recommendation, or where the recommendation is based on an extrapolation of very limited experimental data.

1.2 The Evaluation Procedure

The process of evaluating chemical kinetic data does not conform to a simple set of mathematical rules. There is no “one size fits all” algorithm that can be applied and each reaction must be examined on a case-by-case basis. Consideration of uncertainties in the kinetic and photochemical parameters used in atmospheric models plays a key role in determining the reliability of and uncertainty in the model results. Quite often the cause(s) of differences in experimental results from various laboratories can’t be determined with confidence and making recommendations for the uncertainties of the rate constant is often more difficult than for making recommendations of the Arrhenius parameters themselves. In many cases, investigators suggest possible qualitative reasons for disagreements among datasets. Thus, data evaluators necessarily must consider a variety of factors in assigning a recommendation, including such aspects as the chemical complexity of the system, sensitivities and shortcomings of the experimental techniques employed, similarities or trends in reactivity, and the level of agreement among studies using different techniques.

A recommendation for k(298 K) is typically made by averaging the rate constants from those studies deemed to be of sufficiently high quality / reliability and free from chemical interferences that could have biased the results. In cases where a study provides reliable data over a range of temperatures of atmospheric interest, the value of k(298 K) used in the averaging process is typically obtained from a weighted non-linear least-squares fit to the data from that study, k(T) versus T, assuming equal relative uncertainties in the rate constants reported at the different temperatures. In deriving a recommended Arrhenius temperature dependence (E/R), the selected data sets are examined to ascertain the temperature range over which a standard Arrhenius fit to the data provides an adequate representation. Each data set is then scaled by a constant factor so that the Arrhenius expressions describing the individual data sets give the recommended k(298 K) and a weighted non-linear least-squares fit to all of these scaled data is then made. This typical process is helpful in avoiding biases resulting from systematic errors associated with an individual data set or from the fact that the individual data sets may have been obtained over significantly different temperature ranges. In cases where the selected data sets have been obtained over similar ranges of temperature, a fit to the combined scaled data often yields a value for E/R not very different from that obtained by averaging the E/R values from the individual studies. The recommended Arrhenius pre-exponential factor “A” is then calculated based on the recommended values for k(298 K) and E/R.

1.3 Uncertainty Estimates

The parameters f(298 K) and g given in Table 1 can be used to calculate an estimated rate constant uncertainty at any given temperature, corresponding to approximately one standard deviation, from the following expression:

$$f(T) = f(298\text{ K}) \exp \left| g \left(\frac{1}{T} - \frac{1}{298} \right) \right|$$

where the exponent is an absolute value.

Note that, since f(298 K) and g have been defined to correspond to approximately one standard deviation, f(T) yields a similar uncertainty interval. The more commonly used 95% confidence limits at a given temperature can be obtained by multiplying and dividing the recommended value of the rate constant at that temperature by the factor f²(T). It should be emphasized that the parameter g has been defined exclusively for use with f(298 K) in the

above expression and should not be interpreted as the uncertainty in the Arrhenius activation temperature (E/R). Thus, g is dependent on the value selected for $f(298\text{ K})$. For example, reactions for which $f(298\text{ K})$ is rather large may require only a small value of g to represent an adequate total rate constant uncertainty at other temperatures.

The uncertainty factor $f(298\text{ K})$, corresponding to approximately one standard deviation in the case of normally distributed data, was assigned such that all of the data used in deriving the average are encompassed within the band derived by multiplying and dividing $k(298\text{ K})$ by $f^2(298\text{ K})$, i.e., two standard deviations, which is considered a 95% confidence interval for the evaluation. In some cases, a slightly higher value of $f(298\text{ K})$ may be recommended to encompass outlying data that were not used in the averaging but could not be entirely rejected. The uncertainty factor “ g ” was then selected for use in the $f(T)$ expression described below such that $f^2(T)$ encompasses all of the data used in the evaluation over the temperature range of the recommendation. Neither $f(298\text{ K})$ nor g is derived from a rigorous statistical treatment of the available data, which generally are too limited to permit such analyses and, more importantly, do not follow a normal statistical distribution. Rather, the uncertainty estimation is based on knowledge of the techniques, the difficulties of the experiments, and the potential for systematic errors.

This approach is based on the fact that rate constants are typically known with greater certainty at room temperature where the experimental data are more abundant and often more reliable. The overall uncertainty normally increases at other temperatures where there are fewer data. In addition, data obtained at temperatures far distant from 298 K may be less accurate than at room temperature due to various experimental difficulties or complications.

The uncertainty represented by $f(T)$ is normally symmetric; i.e., the rate constant may be greater than or less than the recommended value, $k(T)$, by the factor $f(T)$. In a few cases in Table 1 asymmetric uncertainties are given in the temperature coefficient. For these cases, the factors by which a rate constant is to be multiplied or divided to obtain, respectively, the upper and lower limits are not equal, except at 298 K where the factor is simply $f(298\text{ K})$.

Finally, there is obviously no way to quantify “unknown” errors. The spread in results among different techniques for a given reaction may provide some basis for an uncertainty estimate, but the possibility of the same, or compensating, systematic errors in all the studies can’t be disregarded. Comparisons among rate constants recommended for similar reactions or for reactions within a homologous series of compounds can also help in the assignment of uncertainty factors. For measurements subject to large systematic errors, the true rate constant may be much further from the recommended value than would be expected and allowed for with any reasonable values of $f(T)$ based on the data available for the evaluation. For example, there have been cases in the past where the recommended rate constants have changed by factors well outside of the uncertainties that had been assigned in the absence of quantitative knowledge of systematic errors. However, as experimental techniques improve together with improved understanding of various reactive processes and with significant expansion of the kinetic and thermodynamic database for the recommendations, exceptionally large changes are becoming less likely.

Rate Constants for Bimolecular Reactions

1.4 O_x Reactions

1.4.1 Table 1A: O_x Reactions

Reaction	Temperature Range of Exp. Data(K) ^a	A-Factor	E/R	k(298 K) ^b	f(298 K) ^c	g	Note
$O + O_2 \xrightarrow{M} O_3$		(See Table 2-1)					
$O + O_3 \rightarrow O_2 + O_2$	220–409	8.0×10^{-12}	2060	8.0×10^{-15}	1.10	200	A1

Shaded areas indicate changes or additions since JPL10-6.

^a Temperature range of available experimental data. This is not necessarily the range of temperature over which the recommended Arrhenius parameters are applicable. See the corresponding note for each reaction for such information.

^b Units are cm³ molecule⁻¹ s⁻¹.

^c f(298 K) is the uncertainty factor at 298 K. To calculate the uncertainty at other temperatures, use the expression:

$$f(T) = f(298 \text{ K}) \exp \left| g \left(\frac{1}{T} - \frac{1}{298} \right) \right|$$

Note that the exponent is an absolute value.

Shaded areas indicate changes or additions since JPL10-6. Italicized blue entries denote estimates.

^a Recommended product channel branching ratios are temperature independent unless noted otherwise.

^b Temperature range of available experimental data. This is not necessarily the range of temperature over which the recommended Arrhenius parameters are applicable. See the corresponding note for each reaction for such information.

^c The total rate coefficient (i.e., O(¹D) loss) is defined as $A \times \exp(-E/RT)$ in units of cm³ molecule⁻¹ s⁻¹.

The rate coefficient for an individual reaction channel, if provided, is defined as Branching Ratio × $A \times \exp(-E/RT)$ in units of cm³ molecule⁻¹ s⁻¹.

^d Units of cm³ molecule⁻¹ s⁻¹.

^e f(298 K) is the uncertainty factor at 298 K. To calculate the uncertainty at other temperatures, use the expression:

$$f(T) = f(298 \text{ K}) \exp \left| g \left(\frac{1}{T} - \frac{1}{298} \right) \right|$$

Note that the exponent is an absolute value.

1.5.2 Notes: O(¹D) Reactions

A2. O(¹D) Reactions. O(¹D) reactions are complex with several possible exothermic reaction pathways, which include (1) collisional (physical) quenching of O(¹D) to ground state oxygen atoms, O(³P), (2) abstraction or addition-elimination reaction, and (3) reactive quenching to form O(³P) and products other than the reactant, including stable and radical species. The recommended total rate coefficient parameters given in the table are for the disappearance of O(¹D). The details of deriving a recommended rate coefficient are given in the note for each reaction. In deriving recommended values, direct measurements are used whenever possible. However, rate coefficients measured via relative rate techniques have been considered for checking consistency in measured elementary reaction rate coefficients. The ratios of the rate coefficients for O(¹D) reactions measured using the same method (and often the same apparatus) may be more accurate and precise than the individual recommended rate coefficients. The ratios of rate coefficients can be obtained from the original references. The weight of the evidence indicates that the results from Heidner and Husain,⁴ Heidner et al.,³ and Fletcher and Husain^{1,2} contain systematic errors and, therefore, are not considered in the determination of the recommendations.

The basis for the product branching ratio recommendations for deactivation and chemical reaction are described in the individual reaction notes. The collisional quenching channel and yield is listed as the first (possibly only) reaction pathway for each reaction given in the table. Reactive quenching channels, i.e., channels that produce O(³P) and reaction products, are included for the O₂ and O₃ reactions, but have not been identified in the majority of the other experimental studies. Bromine, chlorine, and hydrogen are more easily displaced than fluorine from halocarbons and, therefore, typically account for major reaction product yields in the form of BrO, ClO, and OH radicals. The uncertainties in the recommended branching ratios are taken from the experimental studies (see notes) where possible. For some channels, a range of values is provided in parenthesis that is consistent with the other reported uncertainties and a total branching ratio of unity.

A3. O(¹D) + O₂. The recommended 298 K rate coefficient was derived from the studies of Blitz et al.,⁴ Amimoto et al.,^{1,2} Lee and Slanger,^{9,10} Davidson et al.,^{5,6} Dunlea and Ravishankara,⁷ Streit et al.,¹³ Strekowski et al.,¹⁴ and Takahashi et al.¹⁵ The temperature dependence was computed by normalizing the results of Strekowski et al., Dunlea and Ravishankara, and Streit et al. to the 298 K value recommended here. The deactivation of O(¹D) by O₂ leads to the production of O₂(¹Σ) with an efficiency of (80 ± 20)% (Noxon,¹¹ Biedenkapp and Bair,³ Snelling,¹² and Lee and Slanger⁹). O₂(¹Σ) is produced in the v = 0, 1, and 2 vibrational levels in the amounts 60%, 40%, and <3%, respectively (Gauthier and Snelling⁸ and Lee and Slanger⁹). The fractional deactivation of O(¹D) that leads to the excitation of O₂(³Σ) to O₂(¹Δ) is expected to be ~20%. An O₂(¹Σ) yield of (80 ± 20)% is recommended with the O₂(¹Δ) yield accounting for the balance of the reaction.

A4. O(¹D) + O₃. The room temperature rate coefficient was derived from the results of Davidson et al.,^{4,5} Streit et al.,⁸ Amimoto et al.,^{1,2} Wine and Ravishankara,¹⁰⁻¹² Talukdar and Ravishankara,⁹ and Dunlea and Ravishankara.⁶ The reaction of O(¹D) with O₃ gives O₂ + O₂ or O₂ + O + O as products. Davenport et al.³ and Amimoto et al.² report that, on average, one ground state O atom is produced per O(¹D) reacting with O₃. Dunlea et al.⁷ have shown that the yield of O(³P) in this reaction is close to, but not exactly, unity. Dunlea et al. suggest a small, but significant decrease in the O atom yield with decreasing temperature. A O(³P) yield of unity at all temperatures is recommended until the results from the Dunlea et al. study are confirmed. (Table: 06-2, Note: 15-10, Evaluated: 10-6) [Back to Table](#)

A5. O(¹D) + H₂. The recommendation is based on the room temperature rate coefficient data from Davidson et al.,^{2,3} Force and Wiesenfeld,^{4,5} Wine and Ravishankara,¹⁰ Talukdar and Ravishankara,⁸ Blitz et al.,¹ and Vranckx et al.⁹ Davidson et al. (200–350 K) and Vranckx et al. (227–453 K) report that *k* is independent of temperature. Wine and Ravishankara¹⁰ and Vranckx et al.⁹ report the yield of O(³P) to be <4.9% and (0.7 ± 0.7)%, respectively. Hence, the major products of this reaction are H + OH with a recommended yield of unity. Koppe et al.⁶ report a 2.7 times larger rate coefficient at a collisional energy of 0.12 eV. This does not agree with the observations of Davidson et al.³ and Vranckx et al. who reported that *k* is independent of temperature and Matsumi et al.⁷ who report no change in *k* when translationally hot O(¹D) was moderated with Ar.

A6. O(¹D) + H₂O. The recommended *k*(298 K) is based on the results of Davidson et al.,³ Amimoto et al.,¹ Wine and Ravishankara,^{12,13} Gericke and Comes,⁶ Dunlea and Ravishankara,⁵ Carl,² and Takahashi et al.,¹⁰ but is weighted towards the study of Dunlea and Ravishankara because they used several different methods to quantify the water vapor concentration. The results of Lee and Slanger⁸ and Dillon et al.⁴ are consistent with the recommended value. The temperature dependence of the rate coefficient was derived from the data of Streit et al.⁹ and Dunlea and Ravishankara, after normalizing the results from the two studies to the *k*(298 K) value recommended here. The O₂ + H₂ product yield was measured by Zellner et al.¹⁴ to be (1 +0.5/-1)% and Glinski and Birks⁷ to be (0.6 +0.7/-0.6)%. The yield of O(³P) from O(¹D) + H₂O is reported to be less than (4.9 ± 3.2)% by Wine and Ravishankara,¹³ (2 ± 1)% by Takahashi et al.,¹¹ and <0.3% by Carl.² The recommended yield of OH in this reaction is 2.0. To calculate the rates of OH production via O(¹D) reactions in the atmosphere, the quantities of interest are the ratios of the rate coefficients for the reaction of O(¹D) with H₂O to those with N₂ and O₂. Ratio data are given in the original references for this reaction.

A7. O(¹D) + N₂. The rate coefficient recommendation for this reaction is taken from Ravishankara et al.,⁴ which included the results from Strekowski et al.,⁵ Blitz et al.,¹ and Dunlea and Ravishankara³ in their analysis. The more recent results from Takahashi et al.⁶ and Dillon et al.² are in agreement with the recommendation. Strekowski et al. reported the rate coefficient for O(¹D) removal by air and their results are in excellent agreement with the value derived using the current recommendation for O(¹D) removal by N₂ and O₂. The reaction leads to 100% quenching of O(¹D) to O(³P) with no significant reactive channels (see Table 2). (Table: 06-2, Note: 15-10, Evaluated: 10-6) [Back to Table](#)

- (6) Takahashi, K.; Takeuchi, Y.; Matsumi, Y. Rate constants of the O(¹D) reactions with N₂, O₂, N₂O, and H₂O at 295 K. *Chem. Phys. Lett.* **2005**, 410, 196-200, doi:10.1016/j.cplett.2005.05.062.

A8. O(¹D) + N₂O. This reaction has two reactive channels, one producing 2NO and the other producing N₂ + O₂. For atmospheric calculations of NO_x production, the rate coefficient for the channel that produces NO is critical, while the overall rate coefficient is important for deriving the loss rate of N₂O. The recommendation for the overall room temperature rate coefficient for the removal of O(¹D) by N₂O was derived from a

weighted average of the results from Davidson et al.,⁶ Amimoto et al.,¹ Wine and Ravishankara,¹³ Blitz et al.,² Dunlea and Ravishankara,⁸ Carl,⁵ Takahashi et al.,¹¹ Dillon et al.,⁷ and Vranckx et al.¹² The temperature dependence of the rate coefficient was derived from the results of Davidson et al. (204–359 K), Dunlea and Ravishankara (220–370 K), and Vranckx et al. (227–715 K); only data at <400 K were considered in the evaluation, after normalization to the $k(298\text{ K})$ value recommended here for the overall rate coefficient. The recommended rate coefficients for the $\text{N}_2 + \text{O}_2$ and 2NO product channels were evaluated for 298 K, the only temperature at which such data are available. The branching ratio, R , $k(\text{NO} + \text{NO})/k(\text{Total})$ is taken from Cantrell et al.⁴ who reported $R = 0.57$ as well as an analysis of all measurements from 1957–1994 that led them to recommend $R = 0.61 \pm 0.06$, where the uncertainty is the 95% confidence interval. Their recommended branching ratio agrees well with earlier measurements of the quantum yield from N_2O photolysis (Calvert and Pitts³). Dependencies of the branching ratio on $\text{O}(^1\text{D})$ translational energy and temperature are at present not clearly resolved. The recommended rate coefficients for the two channels as a function of temperature were derived assuming that the branching ratio for the two channels is invariant with temperature.

The yield of $\text{O}(^3\text{P})$ from $\text{O}(^1\text{D}) + \text{N}_2\text{O}$ (physical quenching or chemical reaction) has been determined to be <0.04, 0.04 ± 0.02 , 0.056 ± 0.009 , and 0.005 ± 0.002 by Wine and Ravishankara,¹³ Nishida et al.,¹⁰ Carl,⁵ and Vranckx et al.¹² at 298 K, respectively. Vranckx et al. report a slight increase in the $\text{O}(^3\text{P})$ yield with increasing temperature (248–600 K) and their reported yield supersedes the anomalously high value reported by Carl⁵ from the same laboratory. A recommended $\text{O}(^3\text{P})$ yield of <0.01 is based on the Vranckx et al. study. A direct measurement of the NO yield from the $\text{O}(^1\text{D}) + \text{N}_2\text{O}$ reaction in synthetic air by Greenblatt and Ravishankara⁹ and the re-analysis by Dunlea and Ravishankara⁸ agrees very well with the value predicted using the recommended $\text{O}(^1\text{D})$ rate coefficients for N_2 , O_2 , and N_2O and the $\text{O}(^1\text{D}) + \text{N}_2\text{O}$ product branching ratio to give $\text{NO} + \text{NO}$. Better reactive channel branching ratio measurements at stratospheric temperatures and/or measurements of the NO yield in this reaction as a function of temperature below 298 K would be useful.

A9. $\text{O}(^1\text{D}) + \text{NH}_3$. The recommended rate coefficient and temperature dependence is taken from Davidson et al.¹ Sanders et al.² have detected the products $\text{NH}(^1\Delta)$ and OH formed in the reaction. They report that the yield of $\text{NH}(^1\Delta)$ is in the range 3–15% of the amount of the OH detected. A unit reaction yield is recommended.

Further studies are needed to quantify the reaction channel branching ratios.

- (2) Sanders, N. D.; Butler, J. E.; McDonald, J. R. Product branching ratios in the reaction of $O(^1D_2)$ with NH_3 . *J. Chem. Phys.* **1980**, 73, 5381-5383, doi:10.1063/1.439927.

A10. $O(^1D) + HCN$. Strekowski et al.¹ measured the total rate coefficient over the temperature range 211 to 425 K. Their results, the only study available, are recommended. There are several possible exothermic product channel pathways. Strekowski et al. report a $O(^3P)$ yield at 298 K to be ~ 0.3 and observed the $O(^3P)$ yield to have a negative temperature dependence. A significant H atom product channel, ~ 0.35 , was determined at 298 K. The recommended reactive yield was taken from this work.

- (1) Strekowski, R. S.; Nicovich, J. M.; Wine, P. H. Kinetic and mechanistic study of the reactions of $O(^1D_2)$ with HCN and CH_3CN . *ChemPhysChem* **2010**, 11, 3942-3955, doi:10.1002/cphc.201000550.

A11. $O(^1D) + CH_3CN$. Strekowski et al.¹ measured the total rate coefficient over the temperature range 193 to 430 K. Their results, the only study available, are recommended. There are several possible exothermic product channel pathways. Strekowski et al. report a minor $O(^3P)$ collisional quenching yield over the entire temperature range. A H atom yield of 0.16 ± 0.03 at 298 K was reported. The recommended reactive yield was taken from this work.

(New Entry) [Back to Table](#)

- (1) Strekowski, R. S.; Nicovich, J. M.; Wine, P. H. Kinetic and mechanistic study of the reactions of $O(^1D_2)$ with HCN and CH_3CN . *ChemPhysChem* **2010**, 11, 3942-3955, doi:10.1002/cphc.201000550.

A12. $O(^1D) + CO_2$. $k(298\text{ K})$ was derived from the studies of Davidson et al.,³ Streit et al.,⁹ Amimoto et al.,¹ Dunlea and Ravishankara,⁵ Shi and Barker,⁸ and Blitz et al.² Temperature dependence was computed after normalizing the results of Dunlea and Ravishankara and Streit et al. (only the data in the range of 200 to 354 K) to the value of $k(298\text{ K})$ recommended here. The rate coefficient at 195 K reported by Blitz et al. is consistent with the recommendation.

This reaction produces $O(^3P)$ and CO_2 , and is expected to proceed through the formation of a CO_3 complex (see for example DeMore and Dede⁴). This complex formation leads to isotopic scrambling (see for example Perri et al.⁶). There appears to be a small, but non-negligible, channel for $O(^1D)$ quenching. A reactive channel to give CO and O_2 has been reported,⁷ but needs better quantification. A quenching yield of unity is recommended.

A13. $O(^1D) + CH_4$. The recommended overall rate coefficient for the removal of $O(^1D)$ by CH_4 at room temperature is a weighted average of the results from Davidson et al.,⁴ Blitz et al.,¹ Dillon et al.,⁵ and Vranckx et al.¹¹ The temperature dependence of the rate coefficient was derived from the results of Davidson et al. (198–357 K), Dillon et al. (223–297 K), and Vranckx et al. (227–450 K). The recommended rate coefficients for the product channels (a) $CH_3 + OH$, (b) CH_3O or $CH_2OH + H$ and (c) $CH_2O + H_2$ were evaluated for 298 K, the only temperature at which such data are available. Lin and DeMore⁶ analyzed the final products of N_2O/CH_4 photolysis mixtures and concluded that (a) accounted for about 90% and (c) accounted for about 9%. Casavecchia et al.² used a molecular beam experiment to observe H and CH_3O (or CH_2OH) products. They reported that the yield of H_2 was <25% of the yield of H from channel (b). Satyapal et al.⁹ observed the production of H atoms in a pulsed laser experiment and reported an H atom yield of $25 \pm 8\%$. Matsumi et al.⁸ reported the H atom yield in low pressure gas mixtures to be $(15 \pm 3)\%$. Chen et al.³ used laser infrared kinetic spectroscopy to study product formation and report yields of $(67 \pm 5)\%$, $(30 \pm 10)\%$, and 5% for channels a, b, and c, respectively. The yield of $O(^3P)$ via the physical quenching of $O(^1D)$ by CH_4 has been reported by several groups. Wine and Ravishankara,¹² Matsumi et al.,⁷ and Takahashi et al.¹⁰ reported $O(^3P)$ yields of <4.3%, <5%, and <1%, respectively. Vranckx et al.¹¹ reported the most sensitive $O(^3P)$ yield measurement to date and obtained a yield of 0.002 ± 0.003 . We recommend the following branching ratios (a) $(75 \pm 15)\%$, (b) $(20 \pm 10)\%$, (c) $(5 \pm 5)\%$, and no $O(^1D)$ collisional quenching. It is assumed that the branching ratio for the three reactive channels is invariant with temperature.

A14. $O(^1D) + HCl$. The recommended room temperature rate coefficient is based on the measurements of Davidson et al.,³ Wine et al.,⁵ and Chichinin.¹ The temperature dependence is based on the measurements of Davidson et al. Product studies by Wine et al. indicate: $O(^3P) + HCl$ $(9 \pm 5)\%$; $H + ClO$ $(24 \pm 5)\%$; and $OH + Cl$ $(67 \pm 10)\%$. Takahashi et al.⁴ report that the $O(^3P)$ yield is $(15 \pm 4)\%$. Chichinin² report the $H + ClO$ channel to be $(18 \pm 4)\%$. The recommended total reactive yield is based on an average of the Wine et al. and Takahashi et al. results with an estimated uncertainty that encompasses the range of the measurements at the

2 σ level. The H + ClO channel branching ratio is the average of the Wine et al. and Chichinin results with the balance of the reactive channel leading to the formation of Cl + OH.

- (5) Wine, P. H.; Wells, J. R.; Ravishankara, A. R. Channel specific rate constants for reactions of O(¹D) with HCl and HBr. *J. Chem. Phys.* **1986**, *84*, 1349-1354, doi:10.1063/1.450526.

A15. O(¹D) + HF. The recommended values of $k(298\text{ K})$ and the reactive yield are those reported by Sorokin et al.,¹ the only study available. It is assumed that the rate coefficient and product yields are independent of temperature. The reactive products of this reaction are F + OH. The channel to give H + FO is endothermic and, hence, considered to be unimportant.

(Table: 06-2, Note: 06-2, Evaluated: 06-2) [Back to Table](#)

- (1) Sorokin, V. I.; Gritsan, N. P.; Chichinin, A. I. Collisions of O(¹D) with HF, F₂, XeF₂, NF₃, and CF₄: Deactivation and reaction. *J. Chem. Phys.* **1998**, *108*, 8995-9003.

A16. O(¹D) + NF₃. The recommended value for $k(298\text{ K})$ is based on the results of Zhao et al.,⁴ Dillon et al.,² and the value reported by Baasandorj et al.¹ at 296 K. The $k(298\text{ K})$ value reported by Sorokin et al.³ is a factor of two lower and not considered in the recommendation. The recommended Arrhenius parameters are derived from a fit to these data after normalization to $k(298\text{ K})$. Sorokin et al., Zhao et al., and Baasandorj et al. report reactive yields of 0.70, >0.95, and 0.87 +0.13/-0.15, respectively. The recommended reactive yield is an average of the values reported by Zhao et al. and Baasandorj et al. The reactive yield is expected to be independent of temperature. Sorokin et al. observed a high FO radical reaction product yield. Dillon et al. observed a high F-atom yield and attribute the FO formation in the Sorokin et al. study to secondary chemistry. No recommendation is given for the reaction products.

A17. O(¹D) + HBr. The recommended rate coefficient at 298 K was taken from Wine et al.³ There are no reports on the temperature dependence of this rate coefficient. Because it is close to a collisional rate coefficient, the rate coefficient is assumed to be temperature independent. On the basis of O(³P) and H(²S) atom detection, Wine et al. reported physical quenching, HBr + O(³P), in this reaction to be (20 ± 7)%, which is recommended here assuming that no reactive quenching occurs, and the H + BrO reactive product channel to be <4.5%. In a crossed molecular beam study of this reaction, Balucani et al.¹ found the BrO yield to be >(14 ± 6)%. Using transient UV absorption spectroscopy, Cronkhite et al.² found the BrO yield to be (20 ± 4)%, which is recommended here. The balance of the reaction leads to the formation of Br + OH products.

- (3) Wine, P. H.; Wells, J. R.; Ravishankara, A. R. Channel specific rate constants for reactions of O(¹D) with HCl and HBr. *J. Chem. Phys.* **1986**, *84*, 1349-1354, doi:10.1063/1.450526.

A18. O(¹D) + Cl₂. The recommended $k(298\text{ K})$ is based on the studies of Wine et al.⁶ and Sorokin et al.⁴ There are no reports on the temperature dependence of this rate coefficient. The rate coefficient is assumed to be temperature independent because $k(298\text{ K})$ is close to a collisional rate coefficient. Wine et al. report a O(³P) yield of 0.25 ± 0.10 . The Cl atom measurements of Chichinin¹ are consistent with a ClO + Cl yield of 0.7. These values are in excellent agreement with the directly measured ClO yield of $74 \pm 15\%$ by Takahashi et al.⁵ and $77 \pm 10\%$ by Feierabend et al.² Feierabend et al. also reported no measurable (<10%) change in the ClO radical yield at 202 K. An indirect study by Freudenstein and Biedenkapp³ is in reasonable agreement with the yield of ClO. Though energetically allowed, the formation of Cl₂O is expected to be negligible under atmospheric pressure and temperature conditions. On the basis of the Wine et al., Takahashi et al. and Feierabend et al. studies the recommended total reactive and Cl + ClO channel yield is 0.75 ± 0.07 , independent of temperature.

A19. O(¹D) + CCl₂O. The recommended value of $k(298\text{ K})$ is derived from the values reported by Chichinin¹ and Strekowski et al.³ The relative rate study of Jayanty et al.² is consistent with the recommended value. The temperature dependence is taken from Strekowski et al. There are three possible reactive channels: CO + ClO + Cl; CO₂ + 2 Cl; CO₂ + Cl₂. In the stratosphere, all these processes will lead to CO₂ and ClO. Chichinin reports that the above 3 reactions account for $(80 \pm 15)\%$ of O(¹D) loss with 20% leading to O(³P). Strekowski et al. report a O(³P) yield of 0.20 ± 0.04 , which is the basis of the recommendation. The rate coefficient for the loss of CCl₂O via reaction with O(¹D) may be greater than 80% of the overall rate coefficient recommended here due to reactive quenching of O(¹D) to O(³P).

(Table: 06-2, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

- (3) Strekowski, R. S.; Nicovich, J. M.; Wine, P. H. Quenching of O(¹D₂) by Cl₂CO: kinetics and O(³P_i) yield. *Chem. Phys. Lett.* **2000**, *330*, 354-360.

A20. O(¹D) + CCIFO. The recommended rate coefficient is derived from data of Fletcher and Husain.¹ For consistency, the recommended value was derived using a scaling factor (0.5) that corrects for the difference between rate coefficients from the Husain laboratory and the recommendations for other O(¹D) rate coefficients given in this evaluation. Based on consideration of similar O(¹D) reactions, it is assumed that E/R equals zero and the A-factor has been set equal to $k(298\text{ K})$. The branching ratios are estimated based on measured values for similar compounds.

(Table: 82-57, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

- (1) Fletcher, I. S.; Husain, D. The collisional quenching of $O(2^1D_2)$ by $COCl_2$, $COFCl$ and COF_2 using atomic absorption spectroscopy in the vacuum ultraviolet. *J. Photochem.* **1978**, *8*, 355-361.
- A21. $O(^1D) + CF_2O$.** The recommendation is from the data of Wine and Ravishankara.⁴ Their result is preferred over the value of Fletcher and Husain² because it appears to follow the pattern of decreased reactivity with increased fluorine substitution observed for other halocarbons. This reaction has only been studied at 298 K. Based on consideration of similar $O(^1D)$ reactions, it is assumed that E/R equals zero and the A -factor has been set equal to $k(298\text{ K})$. Wine and Ravishankara report $(71 \pm 7)\%$ quenching of $O(^1D)$ to $O(^3P)$. Using relative rate methods, Atkinson et al.¹ and Jayanty et al.³ measured reactive yields of 0.5 ± 0.15 and 0.70 , respectively. The recommended reactive yield is an average of these studies.
(Table: 82-57, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

- A22. $O(^1D) + CH_3Cl$.** The $k(298\text{ K})$ recommendation is an average of the values reported by Matsumi et al.³ and Force and Wiesenfeld.² There are no reports on the temperature dependence of this rate coefficient and it is assumed to be temperature independent. There have been several product channels observed for this reaction. Matsumi et al. observed the formation of H and Cl atoms with a 0.27 ratio. Force and Wiesenfeld reported an $O(^3P)$ yield of 0.09, which is the basis for the total reactive yield recommendation. Takahashi et al.⁴ and Feierabend et al.¹ have reported ClO radical yields that are in excellent agreement, (0.47 ± 0.10) and (0.46 ± 0.06) , respectively, which is recommended. The recommended product branching ratios for the H and Cl atom channels accounts for the remaining product yield in the ratio reported by Matsumi et al.

- A23. $O(^1D) + CCl_4$.** The recommended $k(298\text{ K})$ value is based on the data from Davidson et al.¹ and Force and Wiesenfeld.³ The temperature independence of the rate coefficient is taken from Davidson et al. Force and Wiesenfeld reported this reaction to be $(14 \pm 6)\%$ collisional quenching. Takahashi et al.⁴ and Feierabend et al.² report ClO radical yields of $(90 \pm 19)\%$ and $(79 \pm 4)\%$, respectively. The recommended value is taken from the more precise Feierabend et al. study. Additional product channels may also be possible.

- A24. O(¹D) + CH₃CCl₃.** Nilsson et al.¹ reported a room temperature reactive rate coefficient of $(2.93 \pm 1.2) \times 10^{-10}$ cm³ molecule⁻¹ s⁻¹ (1σ error limit) that was obtained using a relative rate method with CH₄ as the reference compound. The recommended total rate coefficient was calculated assuming a 0.9 reactive yield. (New Entry) [Back to Table](#)

- A25. O(¹D) + CH₃Br.** The recommended rate coefficient at 298 K was taken from Thompson and Ravishankara.² There are no reports on the temperature dependence of this rate coefficient and it is assumed to be temperature independent. Thompson and Ravishankara report that the yield of O(³P) from physical quenching is (0 ± 7)%. On the basis of this single study, a unit reactive yield is recommended. Using transient UV absorption spectroscopy, Cronkhite et al.¹ measured the BrO yield to be (44 ± 5)%. The balance of the reaction is expected to lead to OH radical formation, although no experimental data are currently available. (Table: 94-26, Note: 15-10, Evaluated: 10-6) [Back to Table](#)

- A26. O(¹D) + CH₂Br₂.** The recommendation for *k*(298 K) is based on data from Thompson and Ravishankara,¹ the only study available. There are no reports on the temperature dependence of this rate coefficient and it is assumed to be temperature independent. They report that the yield of O(³P) from physical quenching is (5 ± 7)%. On the basis of this work, a reactive yield of $0.95^{+0.05}_{-0.10}$ is recommended. There are no product studies available, although the major channels are expected to lead to BrO and OH radical formation. (Table: 94-26, Note: 15-10, Evaluated: 10-6) [Back to Table](#)
- (1) Thompson, J. E.; Ravishankara, A. R. Kinetics of O(¹D) reactions with bromocarbons. *Int. J. Chem. Kinet.* **1993**, *25*, 479-487.
- A27. O(¹D) + CHBr₃.** The recommendation for *k*(298 K) is based on data from Thompson and Ravishankara,¹ the only study available. The rate coefficient is large compared to analogous compounds. There are no reports on the temperature dependence of this rate coefficient and it is assumed to be temperature independent. They report that the yield of O(³P) from physical quenching is (32 ± 8)%. A reactive yield of 0.70 ± 0.1 is recommended. There are no product studies available, although the formation of BrO is expected to be a major product channel. (Table: 94-26, Note: 15-10, Evaluated: 10-6) [Back to Table](#)
- (1) Thompson, J. E.; Ravishankara, A. R. Kinetics of O(¹D) reactions with bromocarbons. *Int. J. Chem. Kinet.* **1993**, *25*, 479-487.
- A28. O(¹D) + CH₃F (HFC-41).** The *k*(298 K) recommendation is the average of the measurements of Force and Wiesenfeld² and Schmoltner et al.⁴ There are no reports on the temperature dependence of this rate coefficient and it is assumed to be temperature independent. The O(³P) product yield was reported to be (25 ± 3)% by Force and Wiesenfeld, (11 ± 5)% by Schmoltner et al., and (19 ± 5)% by Takahashi et al.⁵ The recommended branching ratio is an average of these studies, with an uncertainty that encompasses the mean value from all studies at the 2σ level. Burks and Lin¹ reported observing vibrationally excited HF as a product. Park and Wiesenfeld³ observed the formation of OH (X²Π, *v*" = 0, 1) in this reaction. (Table: 94-26, 15-10, Evaluated: 10-6) [Back to Table](#)

A29. $O(^1D) + CH_2F_2$ (HFC-32). The $k(298\text{ K})$ recommendation is based on the measurement of Schmoltner et al.,⁴ the only total rate coefficient study available. Using a relative rate technique, Green and Wayne² measured the loss of CH_2F_2 relative to the loss of N_2O . Their value when combined with the current recommendation for the $O(^1D) + N_2O$ reaction yields a rate coefficient for reactive loss of CH_2F_2 that is about three times the result of Schmoltner et al. Nilsson et al.³ reported a 298 K reactive rate coefficient of $(4.78 \pm 1.02) \times 10^{-11} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ in a relative rate experiment with the $O(^1D) + CH_4$ reaction as the reference. This corresponds to a reactive yield of 0.94 using the current total rate coefficient recommendation. Schmoltner et al. reported an $O(^3P)$ yield of $(70 \pm 11)\%$, which provides the basis of the reaction yield recommendation, assuming that it is due entirely to physical quenching. Burks and Lin¹ reported observing vibrationally excited HF as a product.

- (4) Schmoltner, A. M.; Talukdar, R. K.; Warren, R. F.; Mellouki, A.; Goldfarb, L.; Gierczak, T.; McKeen, S. A.; Ravishankara, A. R. Rate coefficients for reactions of several hydrofluorocarbons with OH and $O(^1D)$ and their atmospheric lifetimes. *J. Phys. Chem.* **1993**, *97*, 8976-8982.

A30. $O(^1D) + CHF_3$ (HFC-23). $k(298\text{ K})$ was measured by Force and Wiesenfeld⁵ and Schmoltner et al.,⁶ while Baasandorj et al.^{2,3} measured the rate coefficient at 298 K and over the temperature range 217–373 K. The results from these studies are in good agreement and the results from the Baasandorj et al. study are recommended. The $O(^3P)$ product yield was reported to be $(77 \pm 15)\%$ by Force and Wiesenfeld and $(102 \pm 3\%)$ by Schmoltner et al. Using a relative rate technique, Baasandorj et al.^{2,3} measured the reactive rate coefficient (relative to the $O(^1D) + NF_3$ reaction) at room temperature. They obtained a reactive yield of 0.25 ± 0.05 , using the current $k(298\text{ K})$ recommendation for the HFC-23 reaction. This result is in good agreement with the Force and Wiesenfeld result. The reaction yield recommendation is based on the more precise Baasandorj et al. studies. There is no apparent explanation for the high quenching yield reported in the Schmoltner et al. study. Although physical quenching is the dominant process, detectable yields of vibrationally excited HF have been reported by Burks and Lin⁴ and Aker et al.,¹ which indicate the formation of HF + CF_2O products.

A31. O(¹D) + CHCl₂F (HCFC-21). The recommendation is based on the total rate coefficient measurements of Davidson et al.¹ over the temperature range 188–343 K. Takahashi et al.³ and Feierabend et al.² report the yield of ClO to be (74 ± 15)% and (73 ± 5)%, respectively. These studies are in excellent agreement and provide the recommendation for the ClO product channel branching ratio. It is expected that the OH radical, or other products, may also be formed in this reaction. An OH channel yield based on comparison with other HCFCs is estimated to be ~0.06.

(Table: 90-1, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

- (1) Davidson, J. A.; Schiff, H. I.; Brown, T. J.; Howard, C. J. Temperature dependence of the rate constants for reactions of O(¹D) atoms with a number of halocarbons. *J. Chem. Phys.* **1978**, *69*, 4277-4279.
- (2) Feierabend, K. J.; Papanastasiou, D. K.; Burkholder, J. B. ClO radical yields in the reaction of O(¹D) with Cl₂, HCl, chloromethanes and chlorofluoromethanes. *J. Phys. Chem. A* **2010**, *114*, 12052-12061, doi:10.1021/jp10776lt.
- (3) Takahashi, K.; Wada, R.; Matsumi, Y.; Kawasaki, M. Product branching ratios for O(³P) atom and ClO radical formation in the reactions of O(¹D) with chlorinated compounds. *J. Phys. Chem.* **1996**, *100*, 10145-10149.

A32. O(¹D) + CHClF₂ (HCFC-22). The rate coefficient recommendation is based on the measurements of Davidson et al.,⁴ Warren et al.⁸ and Baasandorj et al.³ Davidson et al. (173–343 K) and Baasandorj et al. (217–373 K) determined that the rate coefficient has no temperature dependence between 173 and 343 K. Warren et al.⁸ report an O(³P) yield of (28 ± 6)%, which they interpret to be due to collisional quenching of O(¹D) to O(³P). Using a relative rate technique, Baasandorj et al. measured the reactive rate coefficient (relative to the O(¹D) + NF₃ reaction) at room temperature. They obtained a reaction yield of 0.75 ± 0.05, using the current *k*(298 K) recommendation for the NF₃ and HCFC-22 reactions, which is in good agreement with the Warren et al. result. A relative rate measurement by Green and Wayne,⁶ with O(¹D) + N₂O as the reference reaction, is ~25% higher than the recommended *k*(298 K) value. A relative rate measurement by Atkinson et al.² gives a rate coefficient about a factor of two too high. A relative rate measurement by Nilsson et al.,⁷ with O(¹D) + CH₄ as the reference reaction, reported a reactive rate coefficient of (8.69 ± 1.72) × 10⁻¹¹ cm³ molecule⁻¹ s⁻¹ corresponding to a reactive yield of 0.85 ± 0.17 using the current total rate coefficient recommendation. The recommended total reactive yield of 0.75 is taken from the more precise Baasandorj et al. study.

This reaction has been shown to have multiple product channels. Addison et al.¹ reported the following product yields: ClO (55 ± 10)%, CF₂ (45 ± 10)%, O(³P) (28 ± 10/–15)%, and OH 5%, where the O(³P) was interpreted to come from a branch yielding CF₂ and HCl. Feierabend et al.⁵ reported a ClO radical yield of 0.56 ± 0.03, which agrees very well with the Addison et al. measurement and is the basis of the recommendation. An OH product channel yield of 0.05 is recommended and the balance of the reactive yield is assigned to other products.

A33. O(¹D) + CHF₂Br. The recommended rate coefficient at room temperature and its temperature dependence are based on the study of Strekowski et al.² (211–425 K), which is the only available investigation of this reaction. They report a branching ratio for O(³P) production of (39 ± 6)% independent of temperature and a branching ratio for H atom production of 2⁺₁% at 298 K. Cronkhite et al.¹ report a BrO yield of (39 ± 7)% at room temperature. The recommended reactive yield is 0.60 with a significant yield, ~0.2, of unidentified reaction products.

(Table: 06-2, Note: 15-10, Evaluated: 10-6) [Back to Table](#)

- (1) Cronkhite, J. M.; Wine, P. H. Branching ratios for BrO production from reactions of O(¹D) with HBr, CF₃Br, CH₃Br, CF₂ClBr, and CF₂HBr. *Int. J. Chem. Kinet.* **1998**, 30, 555-563.
- (2) Strekowski, R. S.; Nicovich, J. M.; Wine, P. H. Kinetic and mechanistic study of the reaction of O(¹D) with CF₂HBr. *Int. J. Chem. Kinet.* **2001**, 33, 262-270.

A34. O(¹D) + CCl₃F (CFC-11). The recommended rate coefficient is based on the data from Davidson et al.² (173–343 K), Force et al.⁴ (298 K), and Baasandorj et al.¹ (217–373 K), which are in good agreement and show the reaction to be independent of temperature between 173 and 373 K. Force and Wiesenfeld⁴ reported this reaction to be (12 ± 4)% quenching of O(¹D) to O(³P). Using a relative rate technique, Baasandorj et al. measured the reactive rate coefficient (relative to the O(¹D) + N₂O reaction) at room temperature and 240 K (no temperature dependence was observed). They obtained a reactive yield of 0.90 ± 0.07, using the current *k*(298 K) recommendation for the N₂O and their measured total rate coefficient, which is recommended here.

Takahashi et al.⁵ and Feierabend et al.³ report ClO yields of (88 ± 18)% and (79 ± 4)%, respectively, in good agreement with the results from the Force and Wiesenfeld and Baasandorj et al. studies. The more precise Feierabend et al. yield is recommended. On the basis of these recommendations, a ~10% yield of unidentified reaction products is possible.

(Table: 15-10, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

- (1) Baasandorj, M.; Fleming, E. L.; Jackman, C. H.; Burkholder, J. B. O(¹D) kinetic study of key ozone depleting substances and greenhouse gases. *J. Phys. Chem. A* **2013**, 117, 2434-2445, doi:10.1021/jp312781c.
- (2) Davidson, J. A.; Schiff, H. I.; Brown, T. J.; Howard, C. J. Temperature dependence of the rate constants for reactions of O(¹D) atoms with a number of halocarbons. *J. Chem. Phys.* **1978**, 69, 4277-4279.

A35. O(¹D) + CCl₂F₂ (CFC-12). The recommended rate coefficient is based on the data from Davidson et al.² (173–343 K), Force et al.⁴ (298 K), and Baasandorj et al.¹ (217–373 K), which are in good agreement and show the reaction to have a weak negative temperature dependence between 173 and 373 K.

Force and Wiesenfeld⁴ report this reaction to be (14 ± 7)% quenching, which is assumed here to be due to physical quenching and is the basis for the recommendation. Takahashi et al.⁵ report a ClO yield of (87 ± 18)% in good agreement with the Force and Wiesenfeld study. Takahashi et al.⁵ and Feierabend et al.³ report a ClO yields of (87 ± 18)% and (76 ± 6)%, respectively. The more precise Feierabend et al. yield is recommended. On the basis of the recommendations, there may be ~10% yield of unidentified reaction products.

(Table: 15-10, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

A36. O(¹D) + CCIF₃ (CFC-13). The rate coefficient recommendation is based on the room temperature measurement by Ravishankara et al.² There are no reports on the temperature dependence of this rate coefficient and it is assumed to be temperature independent. Ravishankara et al. report (31 ± 10)% collisional quenching of O(¹D) to O(³P). Takahashi et al.³ report yields of O(³P) (16 ± 5)% and ClO (85 ± 18)%. Feierabend et al.¹ report a ClO radical yield of (82 ± 6)%, which is in good agreement with the Takahashi et al. work. The more precise Feierabend et al. ClO product channel yield is recommended for the reactive yield with the balance of the reaction yield assigned to physical quenching. The recommended quenching yield is less than the Ravishankara et al. value, but near to their estimated uncertainty limits. (Table: 92-20, Note: 15-10, Evaluated: 10-6) [Back to Table](#)

A37. O(¹D) + 1,2-*c*-C₄Cl₂F₆ (E,Z). Papadimitriou et al.¹ measured the total and reactive rate coefficients at 296 K for a 0.475:0.525 (E,Z) isomeric mixture. It is assumed that the isomers have equivalent reactivity and their results, the only study available, are recommended. The reactive rate coefficient was measured relative to the N₂O and CCl₂F₂ (CFC-12) reactions and the obtained rate coefficients agreed to within 10% using the current recommendations for the reference reactions. Consistent with the measured reactive yield and the observed trend for other CFCs, it is expected that the reaction is ~15% physical quenching. CF₂O and *c*-C₄F₆ products were observed, although not quantified. (New Entry) [Back to Table](#)

Phys. Chem. A* **2013**, *117*, 11049-11065, doi:10.1021/jp407823k.

A38. O(¹D) + CClBrF₂ (Halon-1211). The recommended rate coefficient at room temperature, *k*(298 K), is based on the data from Thompson and Ravishankara,² the only study available. There are no reports on the temperature dependence of this rate coefficient and it is assumed to be temperature independent. Thompson and Ravishankara report a O(³P) yield of 0.36 ± 0.04. On the basis of this work a total reactive yield of 0.65 is recommended. Cronkhite et al.¹ report a BrO yield of 0.31 ± 0.06 at room temperature. On the basis of these studies, a ~0.34 yield of yet unidentified reaction products is possible. (Table: 94-26, Note: 15-10, Evaluated: 10-6) [Back to Table](#)

- (1) Cronkhite, J. M.; Wine, P. H. Branching ratios for BrO production from reactions of O(¹D) with HBr, CF₃Br, CH₃Br, CF₂ClBr, and CF₂HBr. *Int. J. Chem. Kinet.* **1998**, *30*, 555-563.
- (2) Thompson, J. E.; Ravishankara, A. R. Kinetics of O(¹D) reactions with bromocarbons. *Int. J. Chem. Kinet.* **1993**, *25*, 479-487.

- A39. $O(^1D) + CBr_2F_2$ (Halon-1202).** The k (298 K) recommendation is based on data from Thompson and Ravishankara,¹ the only study available. There are no reports on the temperature dependence of this rate coefficient and it is assumed to be temperature independent. Thompson and Ravishankara report a $O(^3P)$ yield of 0.54 ± 0.06 . Assuming this to be physical quenching, a reactive yield of 0.45 is recommended. (Table: 94-26, Note: 15-10, Evaluated: 10-6) [Back to Table](#)
- (1) Thompson, J. E.; Ravishankara, A. R. Kinetics of $O(^1D)$ reactions with bromocarbons. *Int. J. Chem. Kinet.* **1993**, 25, 479-487.
- A40. $O(^1D) + CBrF_3$ (Halon-1301).** The recommended rate coefficient at room temperature is based on data from Thompson and Ravishankara,³ the only study available. There are no reports on the temperature dependence of this rate coefficient and it is assumed to be temperature independent. Thompson and Ravishankara report a $O(^3P)$ yield of 0.59 ± 0.08 . Lorenzen-Schmidt et al.² measured the $CBrF_3$ removal rate relative to N_2O and report that the rate coefficient for $CBrF_3$ loss in this reaction is $(4.0 \pm 0.4) \times 10^{-11} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$, which is in excellent agreement with the results of Thompson and Ravishankara. Cronkhite et al.¹ report a BrO yield of 0.49 ± 0.07 at room temperature, which is greater than the inferred reactive yield from Thompson and Ravishankara. A reactive yield and BrO yield of 0.45 ± 0.08 is recommended, where the uncertainty limits encompass the results from the Cronkhite et al. and Thompson and Ravishankara studies. (Table: 94-26, Note: 15-10, Evaluated: 10-6) [Back to Table](#)
- (1) Cronkhite, J. M.; Wine, P. H. Branching ratios for BrO production from reactions of $O(^1D)$ with HBr, CF_3Br , CH_3Br , CF_2ClBr , and CF_2HBr . *Int. J. Chem. Kinet.* **1998**, 30, 555-563.
- (2) Lorenzen-Schmidt, H.; Weller, R.; Schrems, O. Kinetics and mechanisms of the reactions of $O(^1D)$ atoms with CF_3Br and CF_3BrCF_2Br in the gas phase and in solid argon matrices. *Ber. Bunsenges. Phys. Chem.* **1994**, 98, 1622-1629.
- (3) Thompson, J. E.; Ravishankara, A. R. Kinetics of $O(^1D)$ reactions with bromocarbons. *Int. J. Chem. Kinet.* **1993**, 25, 479-487.
- A41. $O(^1D) + CF_4$ (CFC-14).** The recommended rate coefficient upper limit is based on the work of Ravishankara et al.,² who report a $(92 \pm 8)\%$ $O(^3P)$ yield. Force and Wiesenfeld¹ measured a quenching rate coefficient about 10 times larger. Shi and Barker³ report an upper limit that is consistent with the recommendation. The small rate coefficient for this reaction makes it vulnerable to interference from reactant impurities. For this reason only an upper limit for the total rate coefficient is recommended with no reactive yield recommendation. (Table: 92-20, Note: 10-6, Evaluated: 10-6) [Back to Table](#)

- A42. $O(^1D) + CH_3CH_2F$ (HFC-161).** The k (298 K) recommendation is based on the data from Schmoltner et al.,¹ the only study available. There are no reports on the temperature dependence of this rate coefficient and it is assumed to be temperature independent. They report that the yield of $O(^3P)$ to be 0.18 ± 0.05 . A reactive yield of 0.82 is recommended. Although no product studies are available, the OH radical is expected to be a major reaction product. (Table: 94-26, Note: 15-10, Evaluated: 10-6) [Back to Table](#)
- (1) Schmoltner, A. M.; Talukdar, R. K.; Warren, R. F.; Mellouki, A.; Goldfarb, L.; Gierczak, T.; McKeen, S. A.; Ravishankara, A. R. Rate coefficients for reactions of several hydrofluorocarbons with OH and $O(^1D)$ and their atmospheric lifetimes. *J. Phys. Chem.* **1993**, 97, 8976-8982.
- A43. $O(^1D) + CH_3CHF_2$ (HFC-152a).** The recommended rate coefficient at room temperature is an average of the data from Warren et al.² and Kono and Matsumi,¹ which agree to within 25%. There are no reports on the temperature dependence of this rate coefficient and it is assumed to be temperature independent. Warren et al. report an $O(^3P)$ yield of 0.54 ± 0.07 . Kono and Matsumi report an $O(^3P)$ yield of 0.34 ± 0.06 , an OH yield of 0.15 ± 0.02 , and that a large fraction of the reaction, ~ 0.50 , leads to unidentified products. There is a

significant discrepancy in the reactive yield between these two studies. The recommended physical quenching yield is an average of the Warren et al. and Kono and Matsumi results, 0.45 ± 0.15 , where the uncertainty limit encompasses the results from both studies. The OH yield from the Kono and Matsumi study is recommended with the balance of the reactive yield assigned to unidentified products. (Table: 10-6, Note: 15-10, Evaluated: 10-6) [Back to Table](#)

- (1) Kono, M.; Matsumi, Y. Reaction processes of O(¹D) with fluoroethane compounds. *J. Phys. Chem. A* **2001**, *105*, 65-69, doi: 10.1021/jp001786q S1089-5639(00)01786-2.
- (2) Warren, R.; Gierczak, T.; Ravishankara, A. R. A study of O(¹D) reactions with CFC substitutes. *Chem. Phys. Lett.* **1991**, *183*, 403-409.

A44. O(¹D) + CH₃CCl₂F (HCFC-141b). The *k*(298 K) recommendation is based upon the measurement of Warren et al.,¹ the only study available. There are no reports on the temperature dependence of this rate coefficient and it is assumed to be temperature independent. Warren et al. report an O(³P) yield of 0.31 ± 0.05 , which assuming physical quenching is the basis for the recommendation. ClO and OH radical reaction product channels are expected to be significant, although no product studies are currently available. (Table: 92-20, Note: 15-10, Evaluated: 10-6) [Back to Table](#)

- (1) Warren, R.; Gierczak, T.; Ravishankara, A. R. A study of O(¹D) reactions with CFC substitutes. *Chem. Phys. Lett.* **1991**, *183*, 403-409.

A45. O(¹D) + CH₃CClF₂ (HCFC-142b). Warren et al.³ (298 K) and Baasandorj et al.¹ (217–373 K) measured the total rate coefficient for this reaction. The room temperature results from these studies are in reasonable agreement, to within 15%, and the average value from these studies is recommended. Baasandorj et al. reported the reaction to be temperature independent over the 217 to 373 K range.

Warren et al. report an O(³P) yield of 0.26 ± 0.05 . Green and Wayne,² who measured the loss of CH₃CF₂Cl relative to the loss of N₂O, obtained a reactive yield of 0.75 ± 0.2 when the current recommendation for O(¹D) + N₂O is used. Using a relative rate technique, Baasandorj et al. measured the reactive rate coefficient (relative to the O(¹D) + HCFC-22 and CFC-115 reactions) at room temperature to be $(1.11 \pm 0.03) \times 10^{-11}$ cm³ molecule⁻¹ s⁻¹. This corresponds to a reactive yield of 0.55 ± 0.05 using the current total rate coefficient recommendations. This is significantly less than reported by Warren et al. The recommended reactive yield is an average of the Warren et al. and Baasandorj et al. results, where the uncertainty limit encompasses the results from both studies.

(Table: 15-10, Note: 15-10, Evaluated: 10-6) [Back to Table](#)

- (1) Baasandorj, M.; Fleming, E. L.; Jackman, C. H.; Burkholder, J. B. O(¹D) kinetic study of key ozone depleting substances and greenhouse gases. *J. Phys. Chem. A* **2013**, *117*, 2434-2445, doi:10.1021/jp312781c.
- (2) Green, R. G.; Wayne, R. P. Relative rate constants for the reactions of O(¹D) atoms with fluorochlorocarbons and with N₂O. *J. Photochem.* **1976/77**, *6*, 371-374.
- (3) Warren, R.; Gierczak, T.; Ravishankara, A. R. A study of O(¹D) reactions with CFC substitutes. *Chem. Phys. Lett.* **1991**, *183*, 403-409.

A46. O(¹D) + CH₃CF₃ (HFC-143a). Kono and Matsumi³ (298 K) and Baasandorj et al.¹ (217–373 K) have measured the total rate coefficient for this reaction. The room temperature results from these studies are in poor agreement with a ~50% difference. Baasandorj et al. reported the reaction to have a weak negative temperature dependence, *E*/*R* = –20 K, over the 217 to 373 K temperature range. The recommended *k*(298 K) is from the average of these two studies and the recommended temperature dependence is taken from Baasandorj et al.

Kono and Matsumi report an O(³P) yield of 0.18 ± 0.04 , an OH yield of 0.38 ± 0.06 , and that ~0.40 of the reaction occurs through unidentified product channels. That is ~0.80 of the reaction leads to loss of CH₃CF₃. The relative rate coefficient measurement by Green and Wayne,² who measured the loss of CH₃CF₃ relative to N₂O, is in poor agreement with the results from Kono and Matsumi. Using the current recommendation for the O(¹D) + N₂O rate coefficient, the Green and Wayne reaction yield would be 1.05 ± 0.20 . Using a relative rate technique, Baasandorj et al. measured the reactive rate coefficient (relative to the O(¹D) + NF₃, HCFC-22, and CFC-115 reactions) at room temperature to be $(3.91 \pm 0.11) \times 10^{-11}$ cm³ molecule⁻¹ s⁻¹. This corresponds to a reactive yield of 0.65 ± 0.05 using the current total rate coefficient recommendations. This is less than obtained from the Kono and Matsumi O(³P) yield measurement. The recommended total reactive

yield is taken from Baasandorj et al. due, in part, to the consistency of results obtained with multiple reference compounds, along with the OH yield from the Kono and Matsumi study.

(Table: 15-10, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

- (2) Green, R. G.; Wayne, R. P. Relative rate constants for the reactions of O(¹D) atoms with fluorochlorocarbons and with N₂O. *J. Photochem.* **1976/77**, *6*, 371-374.
- (3) Kono, M.; Matsumi, Y. Reaction processes of O(¹D) with fluoroethane compounds. *J. Phys. Chem. A* **2001**, *105*, 65-69, doi: 10.1021/jp001786q S1089-5639(00)01786-2.

A47. O(¹D) + CH₂ClCClF₂ (HCFC-132b). The recommendation is based on the room temperature relative rate measurement of Green and Wayne,¹ the only study available. There are no reports on the temperature dependence of this rate coefficient and it is assumed to be temperature independent. Green and Wayne measured the loss of CH₂ClCF₂Cl relative to the loss of N₂O. The recommendation for N₂O is used to obtain the recommended value. There are no product studies available for this reaction. On the basis of results obtained for other halocarbons, a reactive yield of 0.9 is estimated.

(Table: 90-1, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

- (1) Green, R. G.; Wayne, R. P. Relative rate constants for the reactions of O(¹D) atoms with fluorochlorocarbons and with N₂O. *J. Photochem.* **1976/77**, *6*, 371-374.

A48. O(¹D) + CH₂ClCF₃ (HCFC-133a). The *k*(298 K) recommendation is based on the room temperature measurement of Warren et al.,² the only study available. There are no reports on the temperature dependence of this rate coefficient and it is assumed to be temperature independent. Warren et al. report an O(³P) yield of 0.20 ± 0.05. Assuming that all O(³P) production is via physical quenching, a reactive yield of 0.80 ± 0.05 is recommended. No product studies are currently available. The results from the Green and Wayne¹ study, who measured the loss of CH₂ClCF₃ relative to the loss of N₂O, agree with the recommendation when the current recommendation for N₂O is used.

(Table: 92-20, Note: 15-10, Evaluated: 10-6) [Back to Table](#)

- (1) Green, R. G.; Wayne, R. P. Relative rate constants for the reactions of O(¹D) atoms with fluorochlorocarbons and with N₂O. *J. Photochem.* **1976/77**, *6*, 371-374.
- (2) Warren, R.; Gierczak, T.; Ravishankara, A. R. A study of O(¹D) reactions with CFC substitutes. *Chem. Phys. Lett.* **1991**, *183*, 403-409.

A49. O(¹D) + CH₂FCF₃ (HFC-134a). The recommended total rate coefficient at room temperature is based on data from Warren et al.³ and Kono and Matsumi,¹ which are in excellent agreement. There are no reports on the temperature dependence of this rate coefficient and it is assumed to be temperature independent. Warren et al.³ reported an O(³P) yield of 0.94 +0.06/-0.01. Kono and Matsumi reported an O(³P) yield of 0.65 ± 0.06, an OH yield of 0.24 ± 0.04, and that a small fraction of the reaction, ~0.11, leads to other products. Nilsson et al.,² using a relative rate method with O(¹D) + CH₄ as the reference reaction, report a 298 K reactive rate coefficient of (6.10 ± 1.43) × 10⁻¹¹ cm³ molecule⁻¹ s⁻¹, which is greater than the recommended total rate coefficient. The product yields reported in the Kono and Matsumi study are recommended.

(Table: 92-20, Note: 10-6, Evaluated: 10-6) [Back to Table](#)

- (1) Kono, M.; Matsumi, Y. Reaction processes of O(¹D) with fluoroethane compounds. *J. Phys. Chem. A* **2001**, *105*, 65-69, doi: 10.1021/jp001786q S1089-5639(00)01786-2.
- (2) Nilsson, E. J. K.; Andersen, V. F.; Nielsen, O. J.; Johnson, M. S. Rate coefficients for the chemical reactions of CH₂F₂, CHClF₂, CH₂FCF₃ and CH₃CCl₃ with O(¹D) at 298 K. *Chem. Phys. Lett.* **2012**, *554*, 27-32, doi:10.1016/j.cplett.2012.10.001.
- (3) Warren, R.; Gierczak, T.; Ravishankara, A. R. A study of O(¹D) reactions with CFC substitutes. *Chem. Phys. Lett.* **1991**, *183*, 403-409.

A50. O(¹D) + CHCl₂CF₃ (HCFC-123). The *k*(298 K) recommendation is based on the room temperature measurement by Warren et al.,² the only study available. There are no reports on the temperature dependence of this rate coefficient and it is assumed to be temperature independent. The relative rate measurement of Green and Wayne,¹ who measured the loss of CHCl₂CF₃ relative to the loss of N₂O, agrees well with the

recommendation when the current recommendation for N₂O is used. Warren et al. reported an O(³P) yield of 0.21 ± 0.08, which assuming it is due to physical quenching is the basis of the reactive yield recommendation. (Table: 92-20, Note: 15-10, Evaluated: 10-6) [Back to Table](#)

- (1) Green, R. G.; Wayne, R. P. Relative rate constants for the reactions of O(¹D) atoms with fluorochlorocarbons and with N₂O. *J. Photochem.* **1976/77**, 6, 371-374.
- (2) Warren, R.; Gierczak, T.; Ravishankara, A. R. A study of O(¹D) reactions with CFC substitutes. *Chem. Phys. Lett.* **1991**, 183, 403-409.

A51. O(¹D) + CHClFCF₃ (HCFC-124). The *k*(298 K) recommendation is based on the room temperature measurement of Warren et al.,¹ the only study available. There are no reports on the temperature dependence of this rate coefficient and it is assumed to be temperature independent. Warren et al. reported an O(³P) yield of 0.31 ± 0.10, which assuming it is due to physical quenching is the basis of the reactive yield recommendation.

(Table: 92-20, Note: 15-10, Evaluated: 10-6) [Back to Table](#)

- (1) Warren, R.; Gierczak, T.; Ravishankara, A. R. A study of O(¹D) reactions with CFC substitutes. *Chem. Phys. Lett.* **1991**, 183, 403-409.

A52. O(¹D) + CHF₂CF₃ (HFC-125). The total rate coefficient has been measured by Warren et al.⁴ (298 K), Kono and Matsumi³ (298 K), and Baasandorj et al.¹ (217–373 K). The *k*(298 K) results from Kono and Matsumi and Baasandorj et al. are in excellent agreement, while the results from Warren et al. are nearly a factor of 10 greater. Baasandorj et al. report a weak negative temperature dependence, *E*/*R* = –25 K, for the reaction. The results from the Baasandorj et al. study are recommended.

Warren et al. reported an O(³P) yield of 0.85 ± 0.15/–22. Kono and Matsumi reported an O(³P) yield of 0.24 ± 0.04, an OH yield of 0.60 ± 0.10, and that a fraction of the reaction, ~0.15, leads to other products. Green and Wayne² measured the loss of CHF₂CF₃ relative to the loss of N₂O and report a reactive rate coefficient that is significantly greater than the present *k*(298 K) recommendation. Using a relative rate technique, Baasandorj et al. measured the reactive rate coefficient (relative to the O(¹D) + NF₃ and HFC-23 reactions) at room temperature to be (7.33 ± 0.9) × 10^{–12} cm³ molecule^{–1} s^{–1}. This corresponds to a reactive yield of 0.73 ± 0.09 using the current total rate coefficient recommendation. This is in good agreement with that obtained from the Kono and Matsumi O(³P) yield measurement. The recommended total reactive yield of 0.75 ± 0.05 is taken from the Kono and Matsumi and Baasandorj et al. studies with an OH yield of 0.60 ± 0.10 from the Kono and Matsumi study.

(Table: 92-20, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

- (2) Green, R. G.; Wayne, R. P. Relative rate constants for the reactions of O(¹D) atoms with fluorochlorocarbons and with N₂O. *J. Photochem.* **1976/77**, 6, 371-374.
- (3) Kono, M.; Matsumi, Y. Reaction processes of O(¹D) with fluoroethane compounds. *J. Phys. Chem. A* **2001**, 105, 65-69, doi: 10.1021/jp001786q S1089-5639(00)01786-2.
- (4) Warren, R.; Gierczak, T.; Ravishankara, A. R. A study of O(¹D) reactions with CFC substitutes. *Chem. Phys. Lett.* **1991**, 183, 403-409.

A53. O(¹D) + CCl₃CF₃ (CFC-113a). The *k*(298 K) recommendation is taken from the measurement by Baasandorj et al.,¹ the only study available. There are no reports on the temperature dependence of this rate coefficient and it is assumed to be temperature independent. Baasandorj et al. reported a ClO radical yield of 0.79 ± 0.10 (2σ), which represents a lower-limit for the total reactive yield. A total reactive yield of 0.9 is estimated for this reaction with the balance assigned to physical quenching.

(Table: 92-20, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

- (1) Baasandorj, M.; Feierabend, K. J.; Burkholder, J. B. Rate coefficients and ClO radical yields in the reaction of O(¹D) with CClF₂CCl₂F, CCl₃CF₃, CClF₂CClF₂, and CCl₂FCF₃. *Int. J. Chem. Kinet.* **2011**, 43, 393-401, doi:10.1002/kin.20561.

A54. O(¹D) + CCl₂FCClF₂ (CFC-113). The *k*(298 K) recommendation is taken from the studies of Baasandorj et al.¹ (298 K) and Baasandorj et al.² (217–373 K). Baasandorj et al.² found no temperature dependence to the

reaction over the 217–373 K range. Baasandorj et al.¹ reported a ClO radical yield of 0.80 ± 0.10 (2σ), which may represent a lower-limit for the reactive yield. A reactive yield of 0.9 is estimated for this reaction. (Table: 92-20, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

- (1) Baasandorj, M.; Feierabend, K. J.; Burkholder, J. B. Rate coefficients and ClO radical yields in the reaction of O(¹D) with CClF₂CCl₂F, CCl₃CF₃, CClF₂CClF₂, and CCl₂FCF₃. *Int. J. Chem. Kinet.* **2011**, *43*, 393-401, doi:10.1002/kin.20561.

A55. O(¹D) + CCl₂FCF₃ (CFC-114a). The k (298 K) recommendation is taken from the measurement by Baasandorj et al.,¹ the only study available. There are no reports on the temperature dependence of this rate coefficient and it is assumed to be temperature independent. Baasandorj et al.¹ reported a ClO radical yield of 0.79 ± 0.10 (2σ), which may represent a lower-limit for the reactive yield. A total reactive yield of 0.9 is estimated for this reaction.

(Table: 92-20, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

- (1) Baasandorj, M.; Feierabend, K. J.; Burkholder, J. B. Rate coefficients and ClO radical yields in the reaction of O(¹D) with CClF₂CCl₂F, CCl₃CF₃, CClF₂CClF₂, and CCl₂FCF₃. *Int. J. Chem. Kinet.* **2011**, *43*, 393-401, doi:10.1002/kin.20561.

A56. O(¹D) + CClF₂CClF₂ (CFC-114). The total rate coefficient has been measured by Ravishankara et al.³ (298 K), Baasandorj et al.¹ (298 K), and Baasandorj et al.² (217–373 K). The k (298 K) results from these studies are in very good agreement. Baasandorj et al.² report a weak negative temperature dependence, $E/R = -25$ K, for the reaction over the 217–373 K range. The recommended rate coefficient is taken from this study. Ravishankara et al. reported the reaction to be $(25 \pm 9)\%$ quenching of O(¹D) to O(³P). Baasandorj et al.¹ reported a ClO radical yield of 0.85 ± 0.12 (2σ), which may represent a lower-limit for the reaction yield. The reaction yields from the Ravishankara et al. and Baasandorj et al. studies overlap, within the combined uncertainties, and a total reactive yield of 0.9 is recommended.

(Table: 92-20, Note: 15-10, Evaluated: 10-6) [Back to Table](#)

- (1) Baasandorj, M.; Feierabend, K. J.; Burkholder, J. B. Rate coefficients and ClO radical yields in the reaction of O(¹D) with CClF₂CCl₂F, CCl₃CF₃, CClF₂CClF₂, and CCl₂FCF₃. *Int. J. Chem. Kinet.* **2011**, *43*, 393-401, doi:10.1002/kin.20561.
- (2) Baasandorj, M.; Fleming, E. L.; Jackman, C. H.; Burkholder, J. B. O(¹D) kinetic study of key ozone depleting substances and greenhouse gases. *J. Phys. Chem. A* **2013**, *117*, 2434-2445, doi:10.1021/jp312781c.
- (3) Ravishankara, A. R.; Solomon, S.; Turnipseed, A. A.; Warren, R. F. Atmospheric lifetimes of long-lived halogenated species. *Science* **1993**, *259*, 194-199.

A57. O(¹D) + CClF₂CF₃ (CFC-115). The rate coefficient has been measured by Ravishankara et al.² (298 K) and Baasandorj et al.¹ (217–373 K). The k (298 K) values from these studies are in reasonable agreement and the average value is recommended. Baasandorj et al. measured a weak negative temperature dependence, $E/R = -30$ K, for the reaction, which is recommended.

Ravishankara et al. reported an O(³P) yield of 0.70 ± 0.07 . Using a relative rate technique, Baasandorj et al. measured the reactive rate coefficient (relative to the O(¹D) + NF₃, HFC-22, and HFC-125 reactions) at room temperature to be $(5.16 \pm 0.9) \times 10^{-11}$ cm³ molecule⁻¹ s⁻¹. This corresponds to a reactive yield of 0.86 ± 0.06 using the current total rate coefficient recommendations. This is in poor agreement with the Ravishankara et al. value. The recommended reactive yield is taken from Baasandorj et al. due, in part, to the consistency of results obtained with multiple reference compounds. There are no product studies available for this reaction. (Table: 92-20, Note: 15-10, Evaluated: 10-6) [Back to Table](#)

A58. $\text{O}(^1\text{D}) + \text{CBrF}_2\text{CBrF}_2$ (Halon-2402). The $k(298\text{ K})$ recommendation is based on data from Thompson and Ravishankara,² the only study available. They reported an $\text{O}(^3\text{P})$ yield of 0.25 ± 0.07 . Lorenzen-Schmidt et al.¹ measured the Halon removal rate relative to the N_2O removal rate and report a reactive rate coefficient of $(8.8 \pm 1.2) \times 10^{-11}$ (a reactive yield of 0.55), which is significantly less than inferred by Thompson and Ravishankara. The Thompson and Ravishankara product yield is recommended with an uncertainty that encompasses the Lorenzen-Schmidt et al. result at the 2σ level. There are no product studies available for this reaction.

(Table: 94-26, Note: 15-10, Evaluated: 10-6) [Back to Table](#)

A59. $\text{O}(^1\text{D}) + \text{CF}_3\text{CF}_3$ (PFC-116). The $k(298\text{ K})$ recommendation is based on the work of Ravishankara et al.² The small rate coefficient for this reaction makes it vulnerable to interference from reactant impurities. For this reason, $k(298\text{ K})$ may be an upper limit. Ravishankara et al. report a $\text{O}(^3\text{P})$ yield of 0.85 ± 0.15 . Using a relative rate technique, Baasandorj et al.¹ measured the reactive rate coefficient for this reaction, relative to the $\text{O}(^1\text{D}) + \text{CHF}_3$ reaction, to be $<3 \times 10^{-14} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$. On the basis of this study, an upper limit of 0.2 for the reactive yield is recommended.

(Table: 94-26, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

A60. $\text{O}(^1\text{D}) + \text{CF}_3\text{CHFCF}_3$ (HFC-227ea). Baasandorj et al.¹ measured the total rate coefficient over the temperature range 217 to 373 K. Their results, the only study available, are recommended. Using a relative rate technique, Baasandorj et al. measured the reactive rate coefficient for this reaction relative to the $\text{O}(^1\text{D}) + \text{NF}_3$, HFC-23, and HFC-125 reactions to be $(6.99 \pm 0.5) \times 10^{-12} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$. On the basis of this study, a reactive yield of 0.72 ± 0.07 is recommended.

(New Entry) [Back to Table](#)

- (1) Baasandorj, M.; Fleming, E. L.; Jackman, C. H.; Burkholder, J. B. $\text{O}(^1\text{D})$ kinetic study of key ozone depleting substances and greenhouse gases. *J. Phys. Chem. A* **2013**, *117*, 2434-2445, doi:10.1021/jp312781c.

A61. $\text{O}(^1\text{D}) + \text{CHF}_2\text{CH}_2\text{CF}_3$ (HFC-245fa). There are no experimental studies of the rate coefficient for this reaction. The rate coefficient and product yield are estimated based on trends observed for other HFCs.

(New Entry) [Back to Table](#)

A62. $\text{O}(^1\text{D}) + \text{CHF}_2\text{CF}_2\text{CF}_2\text{CHF}_2$ (HFC-338pcc). The $k(298\text{ K})$ recommendation is based on data from Schmoltner et al.,¹ the only study available. There are no reports on the temperature dependence of this rate coefficient and it is assumed to be temperature independent. They reported an $\text{O}(^3\text{P})$ yield of 0.97 ± 0.09 . On the basis of this study, a reactive yield of $0.05^{+0.1}_{-0.05}$ is recommended.

(Table: 94-26, Note: 15-10, Evaluated: 10-6) [Back to Table](#)

- (1) Schmoltner, A. M.; Talukdar, R. K.; Warren, R. F.; Mellouki, A.; Goldfarb, L.; Gierczak, T.; McKeen, S. A.; Ravishankara, A. R. Rate coefficients for reactions of several hydrofluorocarbons with OH and $\text{O}(^1\text{D})$ and their atmospheric lifetimes. *J. Phys. Chem.* **1993**, *97*, 8976-8982.

A63. $\text{O}(^1\text{D}) + c\text{-C}_4\text{F}_8$. The $k(298\text{ K})$ recommendation for perfluorocyclobutane is based on the work of Ravishankara et al.,² the only study available. The small rate coefficient for this reaction makes it vulnerable to interference from reactant impurities. For this reason, $k(298\text{ K})$ may be an upper limit. Ravishankara et al. reported an $\text{O}(^3\text{P})$ yield of $1.00 \pm 0/-0.15$. Using a relative rate technique, Baasandorj et al.¹ measured the reactive rate coefficient for this reaction relative to the $\text{O}(^1\text{D}) + \text{CHF}_3$ reaction to be $<3.5 \times 10^{-14} \text{ cm}^3$

molecule⁻¹ s⁻¹. On the basis of the Baasandorj et al. study, an upper limit of 0.04 for the reaction yield is recommended.

(Table: 92-20, Note: 15-10, Evaluated: 10-6) [Back to Table](#)

- (1) Baasandorj, M.; Hall, B. D.; Burkholder, J. B. Rate coefficients for the reaction of O(¹D) with the atmospherically long-lived greenhouse gases NF₃, SF₅CF₃, CHF₃, C₂F₆, *c*-C₄F₈, *n*-C₅F₁₂, and *n*-C₆F₁₄. *Atmos. Chem. Phys.* **2012**, *12*, 11753-11764, doi:10.5194/acp-12-11753-2012.
- (2) Ravishankara, A. R.; Solomon, S.; Turnipseed, A. A.; Warren, R. F. Atmospheric lifetimes of long-lived halogenated species. *Science* **1993**, *259*, 194-199.

A64. O(¹D) + CF₃CHFCHFCF₂CF₃ (HFC-43-10mee). The *k*(298 K) recommendation is based on data from Schmoltner et al.,¹ the only study available. There are no reports on the temperature dependence of this rate coefficient and it is assumed to be temperature independent. Schmoltner et al. report a O(³P) yield of 0.91 ± 0.04. The recommended branching ratio is taken from the Schmoltner et al. study with a larger uncertainty assigned because there is only a single study for this reaction.

(Table: 94-26, Note: 15-10, Evaluated: 10-6) [Back to Table](#)

- (1) Schmoltner, A. M.; Talukdar, R. K.; Warren, R. F.; Mellouki, A.; Goldfarb, L.; Gierczak, T.; McKeen, S. A.; Ravishankara, A. R. Rate coefficients for reactions of several hydrofluorocarbons with OH and O(¹D) and their atmospheric lifetimes. *J. Phys. Chem.* **1993**, *97*, 8976-8982.

A65. O(¹D) + C₅F₁₂ (CFC-41-12). The *k*(298 K) recommendation is based on data from Ravishankara et al.,² the only total rate coefficient study available. There are no reports on the temperature dependence of this rate coefficient and it is assumed to be temperature independent. The small rate coefficient for this reaction makes it vulnerable to interference from reactant impurities. For this reason, *k*(298 K) may be an upper limit. Ravishankara et al. reported an O(³P) yield of 0.79 ± 0.12. Using a relative rate technique, Baasandorj et al.¹ measured the reactive rate coefficient for this reaction relative to the O(¹D) + CHF₃ reaction to be <5 × 10⁻¹⁴ cm³ molecule⁻¹ s⁻¹. On the basis of the Baasandorj et al. study, an upper limit of 0.12 for the reactive yield is recommended.

(Table: 94-26, Note: 15-10, Evaluated: 10-6) [Back to Table](#)

- (1) Baasandorj, M.; Hall, B. D.; Burkholder, J. B. Rate coefficients for the reaction of O(¹D) with the atmospherically long-lived greenhouse gases NF₃, SF₅CF₃, CHF₃, C₂F₆, *c*-C₄F₈, *n*-C₅F₁₂, and *n*-C₆F₁₄. *Atmos. Chem. Phys.* **2012**, *12*, 11753-11764, doi:10.5194/acp-12-11753-2012.
- (2) Ravishankara, A. R.; Solomon, S.; Turnipseed, A. A.; Warren, R. F. Atmospheric lifetimes of long-lived halogenated species. *Science* **1993**, *259*, 194-199.

A66. O(¹D) + C₆F₁₄ (PFC-51-14). The *k*(298 K) recommendation is based on data from Ravishankara et al.,² the only total rate coefficient study available. The small rate coefficient for this reaction makes it vulnerable to interference from reactant impurities. For this reason, *k*(298 K) may be an upper limit. Ravishankara et al. reported an O(³P) yield of 0.75 ± 0.09. Using a relative rate technique, Baasandorj et al.¹ measured the reactive rate coefficient for this reaction relative to the O(¹D) + CHF₃ reaction to be <1.6 × 10⁻¹³ cm³ molecule⁻¹ s⁻¹. On the basis of the Baasandorj et al. study, an upper limit of 0.16 for the reaction yield is recommended.

(Table: 94-26, Note: 15-10, Evaluated: 10-6) [Back to Table](#)

- (1) Baasandorj, M.; Hall, B. D.; Burkholder, J. B. Rate coefficients for the reaction of O(¹D) with the atmospherically long-lived greenhouse gases NF₃, SF₅CF₃, CHF₃, C₂F₆, *c*-C₄F₈, *n*-C₅F₁₂, and *n*-C₆F₁₄. *Atmos. Chem. Phys.* **2012**, *12*, 11753-11764, doi:10.5194/acp-12-11753-2012.
- (2) Ravishankara, A. R.; Solomon, S.; Turnipseed, A. A.; Warren, R. F. Atmospheric lifetimes of long-lived halogenated species. *Science* **1993**, *259*, 194-199.

A67. O(¹D) + 1,2-(CF₃)₂C-C₄F₆. The *k*(298 K) recommendation is based on data from Ravishankara et al.,¹ the only total rate coefficient study available. They reported an O(³P) yield of 0.84 ± 0.16. The small rate coefficient for this reaction makes it vulnerable to interference from reactant impurities. For this reason only an upper limit for the total rate coefficient and no reactive yield is recommended.

(Table: 94-26, Note: 15-10, Evaluated: 10-6) [Back to Table](#)

- (1) Ravishankara, A. R.; Solomon, S.; Turnipseed, A. A.; Warren, R. F. Atmospheric lifetimes of long-lived halogenated species. *Science* **1993**, 259, 194-199.
- A68. $O(^1D) + C_4F_{10}$.** The $k(298\text{ K})$ recommendation is taken from the estimated upper limit for reactive loss given by Ravishankara et al.,¹ the only study available. The small rate coefficient for this reaction makes it vulnerable to interference from reactant impurities. For this reason an upper limit for the rate coefficient and no reactive yield is recommended.
(Table: 10-6, Note: 15-10, Evaluated: 10-6) [Back to Table](#)
- (1) Ravishankara, A. R.; Solomon, S.; Turnipseed, A. A.; Warren, R. F. Atmospheric lifetimes of long-lived halogenated species. *Science* **1993**, 259, 194-199.
- A69. $O(^1D) + SF_6$.** The $k(298\text{ K})$ recommendation is based on the work of Ravishankara et al.,¹ the only study available. They reported an $O(^3P)$ yield of 0.32 ± 10 . The small rate coefficient for this reaction makes it vulnerable to interference from reactant impurities. For this reason, $k(298\text{ K})$ may be an upper limit and a reactive yield upper limit of 0.7 is recommended.
(Table: 92-20, Note: 15-10, Evaluated: 10-6) [Back to Table](#)
- (1) Ravishankara, A. R.; Solomon, S.; Turnipseed, A. A.; Warren, R. F. Atmospheric lifetimes of long-lived halogenated species. *Science* **1993**, 259, 194-199.
- A70. $O(^1D) + SO_2$.** The room temperature rate coefficient is taken from the work of Zhao et al.,¹ which is the only study for this reaction. Although no studies are available, the reaction rate coefficient is expected to have negligible temperature dependence. Zhao et al. reported the branching ratio for reactive loss to be 0.76 ± 0.12 (2σ), which is the basis of the recommendation.
(Table: 10-6, Note: 15-10, Evaluated: 10-6) [Back to Table](#)
- (1) Zhao, Z.; Laine, P. L.; Nicovich, J. M.; Wine, P. H. Reactive and non-reactive quenching of $O(^1D)$ by the potent greenhouse gases SO_2F_2 , NF_3 , and SF_5CF_3 . *Proc. Nat. Acad. Sci.* **2010**, 107, 6610-6615, doi:10.1073/pnas.0911228107.
- A71. $O(^1D) + SO_2F_2$.** The recommendation is based on the measurements of Dillon et al.¹ and Zhao et al.,² which are in good agreement. Although Dillon et al. report a temperature independent rate coefficient over the temperature range 220–300 K, a weak negative temperature dependence is apparent in their data. Zhao et al. (199–351 K) report a negative temperature dependence, $E/R = -98\text{ K}$, that reproduces both data sets very well and is recommended. Dillon et al. reported a collisional quenching yield of 0.55 ± 0.04 , independent of temperature. The results from Zhao et al. are in agreement with this result, but are less precise. The recommended reactive yield is taken from Dillon et al. Dillon et al. provide qualitative evidence that F atoms may be formed as a reaction product.
(Table: 10-6, Note: 15-10, Evaluated: 10-6) [Back to Table](#)
- (1) Dillon, T. J.; Horowitz, A.; Crowley, J. N. The atmospheric chemistry of sulphuryl fluoride, SO_2F_2 . *Atmos. Chem. Phys.* **2008**, 8, 1547-1557.
- (2) Zhao, Z.; Laine, P. L.; Nicovich, J. M.; Wine, P. H. Reactive and non-reactive quenching of $O(^1D)$ by the potent greenhouse gases SO_2F_2 , NF_3 , and SF_5CF_3 . *Proc. Nat. Acad. Sci.* **2010**, 107, 6610-6615, doi:10.1073/pnas.0911228107.
- A72. $O(^1D) + SF_5CF_3$.** Zhao et al.² and Baasandorj et al.¹ have reported upper limits for the room temperature rate coefficient. There are no reports on the temperature dependence of this rate coefficient and it is assumed to be temperature independent. The determination of the small rate coefficient for this reaction makes it vulnerable to interference from reactant impurities. Baasandorj et al. reported a $k(298\text{ K})$ value that is greater than reported by Zhao et al., which is most likely due to the presence of sample impurities. For this reason only an upper limit for the rate coefficient is recommended. Using a relative rate technique, Baasandorj et al. measured the reactive rate coefficient for this reaction relative to the $O(^1D) + CHF_3$ reaction to be $<5.8 \times 10^{-14}\text{ cm}^3\text{ molecule}^{-1}\text{ s}^{-1}$. On the basis of this study and the Zhao et al. $k(298\text{ K})$ value, an upper limit of 0.3 for the reaction yield is recommended.

1.6 Singlet O₂ Reactions

1.6.1 Table 1A: Singlet O₂ Reactions

Reaction	Temperature Range of Exp. Data (K) ^a	A-Factor	E/R	k(298 K) ^b	f(298 K) ^c	g	Notes
O ₂ (¹ Δ) + O → products	298			<2×10 ⁻¹⁶			A73
O ₂ (¹ Δ) + O ₂ → products	100–450	3.6×10 ⁻¹⁸	220	1.7×10 ⁻¹⁸	1.2	100	A74
O ₂ (¹ Δ) + O ₃ → O + 2O ₂	283–360	5.2×10 ⁻¹¹	2840	3.8×10 ⁻¹⁵	1.2	500	A75
O ₂ (¹ Δ) + H ₂ O → products	298			4.8×10 ⁻¹⁸	1.5		A76
O ₂ (¹ Δ) + N → NO + O	195–300			<9×10 ⁻¹⁷			A77
O ₂ (¹ Δ) + N ₂ → products	298			<10 ⁻²⁰			A78
O ₂ (¹ Δ) + CO ₂ → products	298			<2×10 ⁻²⁰			A79
O ₂ (¹ Σ) + O → products	300			8×10 ⁻¹⁴	5.0		A80
O ₂ (¹ Σ) + O ₂ → products	298			3.9×10 ⁻¹⁷	1.5		A81
O ₂ (¹ Σ) + O ₃ → products	210–370	3.5×10 ⁻¹¹	135	2.2×10 ⁻¹¹	1.15	50	A82
O ₂ (¹ Σ) + H ₂ → products O ₂ (¹ Σ) + H ₂ → 2 OH	173–393	6.4×10 ⁻¹²	600	8.5×10 ⁻¹³ <4×10 ⁻¹⁷ (See Note)	1.15	100	A83
O ₂ (¹ Σ) + H ₂ O → O ₂ + H ₂ O	250–370	3.9×10 ⁻¹²	-125	5.9×10 ⁻¹²	1.3	100	A84
O ₂ (¹ Σ) + N → products	300			<10 ⁻¹³			A85
O ₂ (¹ Σ) + N ₂ → products	203–370	1.8×10 ⁻¹⁵	-45	2.1×10 ⁻¹⁵	1.1	100	A86
O ₂ (¹ Σ) + N ₂ O → products O ₂ (¹ Σ) + N ₂ O → NO + NO ₂	210–370	7.0×10 ⁻¹⁴	-75	9.0×10 ⁻¹⁴ <2×10 ⁻¹⁷ (See Note)	1.3	50	A87
O ₂ (¹ Σ) + CO ₂ → products	245–362	4.2×10 ⁻¹³	0	4.2×10 ⁻¹³	1.2	200	A88

Shaded areas indicate changes or additions since JPL10-6.

^a Temperature range of available experimental data. This is not necessarily the range of temperature over which the recommended Arrhenius parameters are applicable. See the corresponding note for each reaction for such information.

^b Units are cm³ molecule⁻¹ s⁻¹.

^c f(298 K) is the uncertainty factor at 298 K. To calculate the uncertainty at other temperatures, use the expression:

$$f(T) = f(298 \text{ K}) \exp \left| g \left(\frac{1}{T} - \frac{1}{298} \right) \right|$$

Note that the exponent is an absolute value.

1.6.2 Notes: Singlet O₂ Reactions

A73. O₂(¹Δ) + O. The recommendation is based on the upper limit reported by Clark and Wayne.¹ (Table: 92-20, Note: 92-20, Evaluation: 10-6) [Back to Table](#)

- (1) Clark, I. D.; Wayne, R. P. The reaction of O₂(¹Δ_g) with atomic nitrogen and with atomic oxygen. *Chem. Phys. Lett.* **1969**, 3, 405-407.

A74. O₂(¹Δ) + O₂. The recommendation is the average of eight room temperature measurements: Steer et al.,⁹ Findlay and Snelling,⁵ Borrell et al.,² Leiss et al.,⁶ Tachibana and Phelps,¹⁰ Billington and Borrell,¹ Raja et al.,⁸ and Wildt et al.¹¹ The temperature dependence is derived from the data of Findlay and Snelling and Billington and Borrell. Several other less direct measurements of the rate coefficient agree with the recommendation, including Clark and Wayne,³ Findlay et al.,⁴ and McLaren et al.⁷ Wildt et al.¹² report observations of weak emission in the near IR due to collision-induced radiation. Wildt et al.¹³ give rate coefficients for this process. (Table: 92-20, Note: 94-26, Evaluation: 10-6) [Back to Table](#)

A75. O₂(¹Δ) + O₃. The recommendation is the average of the room temperature measurements of Clark et al.,⁴ Findlay and Snelling,⁶ Becker et al.,³ and Collins et al.⁵ Several less direct measurements agree well with the recommendation (McNeal and Cook,⁹ Wayne and Pitts,¹² and Arnold and Comes²). The temperature dependence is from the studies of Findlay and Snelling and Becker et al., which agree very well, although both covered a relatively small temperature range. An earlier study by Clark et al. covered a much larger range and found a much smaller temperature coefficient. The reason for this discrepancy is not clear. The yield of O + 2O₂ products appears to be close to unity, based on many studies of the quantum yield of O₃ destruction near the peak of the Hartley band, e.g. measurements of the number of O₃ molecules destroyed per photon absorbed (von Ellenrieder et al.,¹¹ Ravishankara et al.,¹⁰ Lissi and Heicklen,⁸ and references cited therein) and measurements of O₃ loss and O atom temporal profiles in pulsed experiments (Klais et al.⁷ and Arnold and Comes²). Anderson et al.¹ report that the rate coefficient for atom exchange between O₂(¹Δ) and O₃ is <5 × 10⁻¹⁶ at 300 K.

A76. $O_2(^1\Delta) + H_2O$. The recommendation is the average of the measurements reported by Becker et al.¹ and Findlay and Snelling.³ An earlier study by Clark and Wayne² reported a value about three times larger. (Table: 92-20, Note: 92-20, Evaluation: 10-6) [Back to Table](#)

- (1) Becker, K. H.; Groth, W.; Schurath, U. The quenching of metastable $O_2(^1\Delta_g)$ and $O_2(^1\Sigma_g^+)$ molecules. *Chem. Phys. Lett.* **1971**, *8*, 259-262.

- (3) Findlay, F. D.; Snelling, D. R. Collisional deactivation of $O_2(^1\Delta_g)$. *J. Chem. Phys.* **1971**, *55*, 545-551.

A77. $O_2(^1\Delta) + N$. The recommendation is an upper limit based upon the measurement reported by Westenberg et al.,⁴ who used ESR to detect $O_2(X^3\Sigma$ and $a^1\Delta)$, $O(^3P)$ and $N(^4S)$ with a discharge flow reactor. They used an excess of $O_2(^1\Delta)$ and measured the decay of N and the appearance of O at 195 and 300 K. They observed that the reaction of N with $O_2(^1\Delta)$ is somewhat slower than its reaction with $O_2(^3\Sigma)$. The recommended rate constant value for the latter provides the basis for the recommendation. Clark and Wayne^{1,2} and Schmidt and Schiff³ reported observations of an $O_2(^1\Delta)$ reaction with N that is about 30 times faster than the recommended limit. Schmidt and Schiff attribute the observed loss of $O_2(^1\Delta)$ in excess N to a rapid energy exchange with some constituent in discharged nitrogen, other than N. - A82. $O_2(^1\Sigma) + O_3$.** The recommendation is based on the room temperature measurements of Gilpin et al.,⁶ Gauthier and Snelling,⁵ Slanger and Black,⁹ Choo and Leu,³ Shi and Barker,⁸ Turnipseed et al.,¹¹ and Dunlea et al.⁴ Measurements by Snelling,¹⁰ Amimoto and Wiesenfeld,¹ and Ogren et al.⁷ are in agreement with the recommendation. The value from the study of Biedenkapp and Bair² is lower than the recommended value. The temperature dependence is taken from the results of Dunlea et al., who measured the rate coefficient between 210 and 370 K. The results of Choo and Leu, which encompassed 295–362 K, are consistent with the recommended value. This reaction has multiple product channels. The yield of $O + 2O_2$ products is reported to be $(70 \pm 20)\%$ by Slanger and Black and Amimoto and Wiesenfeld. The remaining $\sim 30\%$ of the reaction is expected to lead to quenching to $O_2(^1\Delta$ or $^3\Sigma)$ while leaving ozone intact; the electronic state of O_2 that is produced in all these channels is not known.

A83. $O_2(^1\Sigma) + H_2$. The rate coefficient for this reaction, at or around 298 K, has been measured by Kohse-Höinghaus and Stuhl,⁶ Braithwaite et al.,² Choo and Leu,³ Singh and Setser,⁸ Wildt et al.,¹⁰ Michelangeli et al.,⁷ Borrell and Richards,¹ Hohmann et al.,⁵ and Talukdar et al.⁹ $k(298\text{ K})$ was derived from the results of all of the above studies except for the results of Singh and Setser and Borrell and Richards, which are clearly outside of the range of values obtained by others.

The temperature dependence of the rate coefficient was computed using the results of Braithwaite et al., Hohmann et al., and Talukdar et al. The results of Kohse-Höinghaus and Stuhl were not included, because they are assumed to be superseded by those of Hohmann et al. from the same group. It is suspected that the Kohse-Höinghaus and Stuhl study was hampered by impurities in their system, as discussed in Talukdar et al.

The rate coefficient for the reaction to produce 2 OH radicals is listed separately as an upper limit at 298 K and is based on the results of Talukdar et al. The same upper limit was shown to be valid even at 209 K. Therefore, this upper limit is recommended for all atmospheric calculations.

This reaction could also produce $O(^3P) + H_2O$. However, there is no evidence for the formation of $O(^3P)$ (Dunlea et al.⁴). Therefore, it is assumed that $O_2(^1\Sigma)$ is removed exclusively via quenching. The electronic state of O_2 that is produced is not known.

A84. $O_2(^1\Sigma) + H_2O$. The recommendation is the average of room temperature measurements reported by Stuhl and Niki,⁸ Avilés et al.,¹ Shi and Barker,⁷ and Dunlea et al.³ Measurements reported by O'Brien and Myers⁶ are lower, most likely due to an interference from $O_2(^1\Sigma)$ regeneration. The results of Derwent and Thrush² and Thomas and Thrush⁹ are in agreement with the recommendation. The value reported by Gauthier and Snelling⁵ has a very large uncertainty and hence overlaps with the recommendation. It is not clear why the results of Filseth et al.⁴ are lower than all the other reported values; perhaps, they had an error in measuring water vapor concentration. The temperature dependence of the reaction is taken from the only reported value of Dunlea et al. Wildt et al.¹⁰ report that the yield of $O_2(^1\Delta)$ is greater than 90%. There are no thermodynamically allowed reactive channels for this reaction. Therefore, the reaction products are written as $O_2 + H_2O$.³

A85. $O_2(^1\Sigma) + N$. The recommendation is based on the upper limit reported by Slanger and Black.¹

(Table: 92-20, Note: 92-20, Evaluation: 10-6) [Back to Table](#)

- (1) Slanger, T. G.; Black, G. Interactions of $O_2(b^1\Sigma_g^+)$ with $O(^3P)$ and O_3 . *J. Chem. Phys.* **1979**, *70*, 3434-3438.

A86. $O_2(^1\Sigma) + N_2$. The recommendation for room temperature is the average of measurements reported by Izod and Wayne,⁵ Stuhl and Welge,¹¹ Filseth et al.,⁴ Martin et al.,⁷ Kohse-Höinghaus and Stuhl,⁶ Choo and Leu,² Wildt et al.,¹² Shi and Barker,¹⁰ and Dunlea et al.³ Less direct measurements reported by Noxon,⁹ Myers and O'Brien,⁸ and Chatha et al.¹ are consistent with the recommendation. The temperature dependence of the rate coefficient is derived from the results of Kohse-Höinghaus and Stuhl between 203 and 349 K and of Dunlea et al. between 210 and 370 K.

There are no exothermic reaction channels. The channel to produce 2 NO molecules is endothermic by 5.6 kcal mol⁻¹ at 298 K.

A87. $O_2(^1\Sigma) + N_2O$. The rate coefficient for the removal of $O_2(^1\Sigma)$ by N_2O at 298 K is derived from the studies of Filseth et al.,³ Borrell et al.,¹ and Dunlea et al.² The results of Gauthier and Snelling⁴ have a large uncertainty, which overlaps the recommended value within their quoted error bars. The temperature dependence of this rate coefficient is taken from Dunlea et al., the only temperature dependent study.

There are many possible reactive channels for this reaction:

Dunlea et al. have placed upper limits of $<2 \times 10^{-4}$, $<1 \times 10^{-3}$, and $<3 \times 10^{-3}$ for channel (a + c), channel (b), and overall N_2O loss, respectively, from this reaction at 298 K. Based on these results, we recommend an upper limit for NO_x production of $<2 \times 10^{-17} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$. The upper limit for NO_x production from this reaction is assumed to be valid for all atmospheric temperatures.

A88. $O_2(^1\Sigma) + CO_2$. The recommendation is the average of measurements reported by Filseth et al.,⁵ Davidson et al.,³ Avilés et al.,¹ Muller and Houston,⁷ Choo and Leu,² Wildt et al.,¹⁰ Hohmann et al.,⁶ Dunlea et al.,⁴ and Shi and Barker⁸ at room temperature. The temperature dependence is from the work of Choo and Leu. Muller and Houston and Singh and Setser⁹ give evidence that $O_2(^1\Delta)$ is a product. Wildt et al. report a $O_2(^1\Delta)$ yield of $\geq 90\%$.

1.7 HO_x Reactions

1.7.1 Table 1B: HO_x Reactions

Reaction	Temperature Range of Exp. Data (K) ^a	A-Factor	E/R	k(298 K) ^b	f(298 K) ^c	g	Note
O + OH → O ₂ + H	136–515	1.8×10 ⁻¹¹	-180	3.3×10 ⁻¹¹	1.15	50	B1
O + HO ₂ → OH + O ₂	229–391	3.0×10 ⁻¹¹	-200	5.9×10 ⁻¹¹	1.05	50	B2
O + H ₂ O ₂ → OH + HO ₂	283–386	1.4×10 ⁻¹²	2000	1.7×10 ⁻¹⁵	1.2	100	B3
H + O ₂ $\xrightarrow{M}$ HO ₂		(See Table 2-1)					
H + O ₃ → OH + O ₂	196–424	1.4×10 ⁻¹⁰	470	2.9×10 ⁻¹¹	1.1	40	B4
H + HO ₂ → 2 OH	245–300	7.2×10 ⁻¹¹	0	7.2×10 ⁻¹¹	1.2	100	B5
→ O + H ₂ O		1.6×10 ⁻¹²	0	1.6×10 ⁻¹²	1.5	100	
→ H ₂ + O ₂		6.9×10 ⁻¹²	0	6.9×10 ⁻¹²	1.4	100	
OH + O ₃ → HO ₂ + O ₂	190–357	1.7×10 ⁻¹²	940	7.3×10 ⁻¹⁴	1.15	50	B6
OH + H ₂ → H ₂ O + H	200–1050	2.8×10 ⁻¹²	1800	6.7×10 ⁻¹⁵	1.05	100	B7
OH + HD → products	248–418	5.0×10 ⁻¹²	2130	4.0×10 ⁻¹⁵	1.15	50	B8
OH + OH → H ₂ O + O	233–580	1.8×10 ⁻¹²	0	1.8×10 ⁻¹²	1.25	50	B9
$\xrightarrow{M}$ H ₂ O ₂		(See Table 2-1)					
OH + HO ₂ → H ₂ O + O ₂	252–420	4.8×10 ⁻¹¹	-250	1.1×10 ⁻¹⁰	1.15	50	B10
OH + H ₂ O ₂ → H ₂ O + HO ₂		(See Note)					B11
HO ₂ + O ₃ → OH + 2O ₂	197–413	1.0×10 ⁻¹⁴	490	1.9×10 ⁻¹⁵	1.15	80	B12
HO ₂ + HO ₂ → H ₂ O ₂ + O ₂	222–1120	3.0×10 ⁻¹³	-460	1.4×10 ⁻¹²	1.15	100	B13
$\xrightarrow{M}$ H ₂ O ₂ + O ₂		2.1×10 ⁻³³ [M]	-920	4.6×10 ⁻³² [M]	1.2	200	
HO ₂ + HO ₂ · H ₂ O → products	298–350	5.4×10 ⁻¹¹	410	1.4×10 ⁻¹¹	2	100	B14

Shaded areas indicate changes or additions since JPL10-6.

^a Temperature range of available experimental data. This is not necessarily the range of temperature over which the recommended Arrhenius parameters are applicable. See the corresponding note for each reaction for such information.

^b Units are cm³ molecule⁻¹ s⁻¹.

^c f(298 K) is the uncertainty factor at 298 K. To calculate the uncertainty at other temperatures, use the expression:

$$f(T) = f(298 \text{ K}) \exp \left| g \left(\frac{1}{T} - \frac{1}{298} \right) \right|$$

Note that the exponent is an absolute value.

1.7.2 Notes: HO_x Reactions

B1. O + OH. The recommended rate coefficient was obtained from the studies of Westenberg et al.⁸ (228–340 K), Lewis and Watson⁴ (221–499 K), Howard and Smith² (250–515 K), Smith and Stewart⁷ (158–294 K), and Robertson and Smith⁵ (136–377 K). The recommendation is consistent with earlier work near room temperature as reviewed by Lewis and Watson,⁴ and with the measurements of Brune et al.¹ (300 K), and Robertson and Smith⁶ (295 K). The ratio $k(\text{O} + \text{HO}_2)/k(\text{O} + \text{OH})$ measured by Keyser³ agrees with the recommended values.

B2. O + HO₂. The recommended values are based on the results of studies over a range of temperatures by Keyser⁵ (229-372 K) and Nicovich and Wine⁹ (266–391 K) and the room temperature studies of Sridharan et al.,¹² Ravishankara et al.,¹⁰ and Brune et al.¹ Earlier studies by Hack et al.⁴ and Burrows et al.^{2,3} are not considered because the $\text{OH} + \text{H}_2\text{O}_2$ reaction was important in these studies and the value used for its rate constant in their analyses has been shown to be in error. A study by Lii et al.⁸ is also not considered because of the insensitivity of the observed decays to $\text{O} + \text{HO}_2$. Data from Ravishankara et al.¹⁰ at 298 K show no dependence on pressure between 10 and 500 Torr N₂. The ratio $k(\text{O} + \text{HO}_2)/k(\text{O} + \text{OH})$ measured by Keyser⁶ agrees with the rate constants recommended here. Sridharan et al.¹¹ showed that the reaction products correspond to abstraction of an oxygen atom from HO_2 by the O reactant. Keyser et al.⁷ reported <1% $\text{O}_2(^1\Delta)$ yield.

B3. $O + H_2O_2$. There are two direct studies of the $O + H_2O_2$ reaction: Davis et al.² (283–368 K) and Wine et al.⁴ (298–386 K). The recommended value is a fit to the combined data. An indirect measurement of the E/R value by Roscoe³ is consistent with the recommendation. The A factor for both data sets is quite low compared to similar atom-molecule reactions. A somewhat higher activation barrier reported by Albers et al.¹ over the temperature range 370–800 K is suggestive of a non-linear temperature dependence. (Table: 06-2, Note: 06-2, Evaluated: 10-6) [Back to Table](#)

- (1) Albers, E. A.; Hoyermann, K.; Wagner, H. G.; Wolfrum, J. Absolute measurements of rate coefficients for the reactions of H and O atoms with H_2O_2 and H_2O . *Proc. Combust. Inst.* **1971**, *13*, 81-88.

B4. $H + O_3$. The recommendation is an average of the results of Lee et al.⁸ (219–360 K) and Keyser⁷ (196–424 K), which are in agreement over the 220–360 K range. Results by Seeley et al.⁹ and Finlayson-Pitts and Kleindienst³ agree well with the present recommendation. An earlier study by Clyne and Monkhouse¹ is in very good agreement on the temperature dependence in the range 300–560 K, but lies about 60% below the recommended values. Although we have no reason not to believe the Clyne and Monkhouse values, we prefer the two studies that are in agreement, especially since they were carried out over the temperature range of interest. Reports of a channel forming $HO_2 + O$ (Finlayson-Pitts and Kleindienst³: ~25%, and Force and Wiesenfeld⁵: ~40%) have been contradicted by other studies (Howard and Finlayson-Pitts⁶: <3%; Washida et al.¹¹: <6%; Finlayson-Pitts et al.⁴: <2%; and Dodonov et al.²: <0.3%). Secondary chemistry is believed to be responsible for the observed O-atoms in this system. Washida et al.¹⁰ measured an upper limit (<0.1%) for the production of singlet molecular oxygen for the reaction. (Table: 06-2, Note: 06-2, Evaluated: 10-6) [Back to Table](#)

- (11) Washida, N.; Akimoto, H.; Okuda, M. $O_2^*(a^1\Delta_g)$ in the reaction of $H + O_3$. *J. Chem. Phys.* **1980**, 72, 5781-5783.

B5. $H + HO_2$. There are five studies of this reaction: Hack et al.² (293 K), Hack et al.¹ (293 K), Thrush and Wilkinson⁸ (298 K), Sridharan et al.⁷ (296 K), and Keyser⁴ (245–300 K). Related early work and combustion studies are referenced in Sridharan et al. All five studies used discharge flow systems. It is difficult to obtain a direct measurement of the rate constant for this reaction because both reactants are radicals and the products OH and O are reactive toward the HO_2 reactant. The recommendation is based on the kinetics and product data of Sridharan et al. and Keyser, because those measurements were the most direct and required the fewest corrections. Keyser found the rate coefficient and product yields to be independent of temperature for $245 < T < 300$ K. The total rate constant measurements of, $(5.0 \pm 1.3) \times 10^{-11} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ by Thrush and Wilkinson⁸ and $(4.65 \pm 1) \times 10^{-11}$ by Hack et al.¹ are significantly less than the recommended total rate constant, $8.05 \times 10^{-11} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$. Hislop and Wayne,³ Keyser et al.,⁵ and Michelangeli et al.⁶ reported on the yield of $O_2(b^1\Sigma)$ formed in the $H_2 + O_2$ channel as $(2.8 \pm 1.3) \times 10^{-4}$, $< 8 \times 10^{-3}$, and $< 2.1 \times 10^{-2}$, respectively as a fraction of the overall reaction.

B6. $OH + O_3$. The recommended values are based on the results of studies over a range of temperatures by Anderson and Kaufman¹ (220–450 K), Ravishankara et al.⁵ (238–357 K), Smith et al.⁶ (240–295 K) and Nizkorodov et al.⁴ (190–315 K) and the room temperature measurements of Kurylo,³ Zahniser and Howard,⁷ and Kulcke et al.² The recommended E/R and $k(298 \text{ K})$ values are based on averages of the individual E/R and $k(298 \text{ K})$ values obtained in the above mentioned studies. The value reported by Kulcke et al.² has been corrected for a minor contribution from $k(HO_2 + O_3)$.

B7. OH + H₂. The OH + H₂ reaction has been the subject of numerous studies. The recommendation is fixed to the average of eleven studies at 298 K: Greiner,² Stuhl and Niki,⁷ Westenberg and deHaas,¹⁰ Smith and Zellner,⁶ Atkinson et al.,¹ Overend et al.,⁴ Tully and Ravishankara,⁹ Zellner and Steinert,¹¹ Ravishankara et al.,⁵ Talukdar et al.,⁸ and Orkin et al.³ The temperature dependent studies of Orkin et al. (200–480 K), Talukdar et al. (230–420 K), and Ravishankara et al. (250–1050 K) find that the reaction does not follow a simple Arrhenius expression over a large range of temperature. The recommended temperature dependence is based on the average of *E/R* values determined in the above-mentioned studies for temperatures below 300 K. Accordingly, the recommended Arrhenius expression is only valid between 200–300 K. Even over this range the simple Arrhenius expression likely overestimates, near 250 K, and underestimates, near 200 K, the data by approximately 10%.

B8. OH + HD. The recommendation is based on direct measurements made by Talukdar et al.² using pulsed photolysis-laser induced fluorescence over the temperature range 248–418 K. The recommendation is in excellent agreement with the ratio *k*(OH + H₂)/*k*(OH + HD) = 1.65 ± 0.05 at 298 K reported by Ehhalt et al.¹ when combined with the recommended *k*(OH + H₂).

B9. OH + OH. The recommendation for the OH + OH reaction is the average of eight measurements performed near 298 K at low bath gas pressures: Westenberg and deHaas,⁹ McKenzie et al.,⁶ Clyne and Down,³ Trainor and von Rosenberg,⁷ Farquharson and Smith,⁴ Wagner and Zellner,⁸ Bedjanian et al.,² and Bahng and MacDonald.¹ The rate coefficients reported in these studies fall in the range (1.4–2.7) × 10⁻¹² cm³ molecule⁻¹ s⁻¹. Wagner and Zellner (250–580 K) reported a slight positive temperature dependence of the rate coefficient in contrast with that reported by Bedjanian et al. (233–360 K), who report a small negative

temperature dependence. The earlier work of Wagner and Zellner may have been complicated by an increased contribution of the OH + H reaction due to an underestimate of its reaction rate. Theoretical calculations by Harding and Wagner⁵ suggest that tunneling substantially influences the reaction rate coefficient. In taking account of the tunneling contribution, the rate coefficient is found to have a minimum value near room temperature. In view of the predicted behavior and given that the experimental data are consistent with each other, within the stated uncertainties, the recommendation is a temperature independent value for the rate coefficient over the temperature range 200–300 K.

B10. OH + HO₂. A study by Keyser⁸ appears to resolve a discrepancy among low-pressure discharge flow experiments that all gave rate coefficients near $7 \times 10^{-11} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$: Keyser,⁷ Thrush and Wilkinson,¹⁶ Sridharan et al.,^{13,14} Temps and Wagner,¹⁵ Rozenshtein et al.,¹¹ and atmospheric pressure studies that gave rate coefficients near $11 \times 10^{-11} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$: Lii et al.,¹⁰ Hohanadel et al.,⁶ DeMore,³ Cox et al.,² Burrows et al.,¹ and Kurylo et al.⁹ Laboratory measurements using a discharge flow experiment and a chemical model analysis of the results by Keyser⁸ demonstrate that the previous discharge flow measurements were probably subject to interference from small amounts of O and H. In the presence of excess HO₂, these atoms generate OH and result in a rate coefficient measurement that falls below the true value. The temperature dependence is from Keyser,⁸ who covered the range 254 to 382 K. A flow tube study by Schwab et al.¹² reported $k = (8.0 + 3/-4) \times 10^{-11} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$. These workers measured the concentrations of HO₂, OH, O, and H and used a computer model of the relevant reactions to test for interference. A flow tube study by Dransfeld and Wagner⁴ employing an isotope labeled ¹⁸OH reactant obtained $k = (11 \pm 2) \times 10^{-11} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ in good agreement with the recommendation. They attributed about half of the reactive events to isotope scrambling because control experiments with ¹⁶OH gave $k = 6 \times 10^{-11} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$. It should be noted that their control experiments were subject to the errors described by Keyser⁸ due to the presence of small amounts of H and O, whereas their ¹⁸OH measurements were not. Kurylo et al.⁹ found no evidence of significant scrambling in isotope studies of the OH and HO₂ reaction. An additional careful study of the reaction temperature dependence would be useful. Hippler and Troe⁵ have analyzed data for this reaction at temperatures up to 1250 K. In summary, this has historically been a difficult reaction to study. Earlier problems appear to have been resolved, as discussed above, and results now tend to converge on a central value, but the recommended value is still subject to a large uncertainty.

B11. $\text{OH} + \text{H}_2\text{O}_2$. The rate coefficient for this reaction shows non-Arrhenius behavior between 96 and 1250 K with a minimum value near room temperature. Data from a number of studies are in relatively good agreement between 300 and 500 K after normalization to account for the H_2O_2 UV absorption cross section recommendation in this evaluation. Hippler and Troe¹ analyzed data for this reaction at temperatures up to 1250 K. The studies of Keyser² (245–423 K), Sridharan et al.⁷ (250–459 K), Wine et al.¹¹ (273–410 K), Kurylo et al.³ (250–370 K), Lamb et al.⁴ (241–413 K), and Vaghjiani et al.⁹ (273–410 K) show that the reaction displays a small positive temperature dependence ($E/R = \sim 160$ K) over the 300–500 K range. Measurements at room temperature by Marinelli and Johnston,⁵ Riffault et al.,⁶ Turnipseed et al.,⁸ and Vakhtin et al.¹⁰ agree with the other studies. A value of $1.8 \times 10^{-12} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ is obtained by averaging the room temperature data. Lamb et al. and Vaghjiani report that k increases slightly with decreasing temperature for temperatures below 300 K while other studies show a slight positive temperature dependence. Vakhtin et al. used a pulsed Laval nozzle technique to study the reaction at very low temperatures (96–165 K) and report a significant increase in k with decreasing temperature. They suggest that the reaction mechanism includes the formation of a hydrogen-bonded complex. The recommendation is a temperature independent value of $1.8 \times 10^{-12} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ with $f(298 \text{ K}) = 1.15$ and $g = 45$ over the temperature range of 200–300 K.

B12. HO₂ + O₃. The recommended values are based on results of studies over a range of temperatures by DeMore¹ at 231 to 334 K, Zahniser and Howard⁹ at 245 to 365 K, Manzanares et al.⁴ at 298 K, Sinha et al.⁷ at 243 to 413 K, Wang et al.⁸ at 233 to 400 K, and Herndon et al.³ at 200 to 298 K. The data of Simonaitis and Hecklen⁶ and DeMore and Tschuikow-Roux² were not considered. The temperature dependence studies show varying degrees of curvature in the Arrhenius plots, with the *E*/*R* decreasing at lower temperature. This is especially evident in the low temperature data of Herndon et al. where a number of measures were taken to control potential kinetic complications. The recommended *E*/*R* and *k*(298 K) values are based on averages of the individual *E*/*R* and *k*(298 K) values. Furthermore, only data at temperatures less than 298 K were used for the *E*/*R* determination. Accordingly, the recommendation is not valid for *T* > 298 K. Additional temperature dependence data are needed for this reaction over a larger range to more fully characterize the non-linear behavior of the rate constant. The mechanism of the reaction has been studied using ¹⁸O labeled HO₂ by Sinha et al., who reported that the reaction occurs (75 ± 10)% via H atom transfer at 297 K and by Nelson and Zahniser,⁵ who reported branching ratios for H transfer vs O transfer over the range 226–355 K. They report that the H atom transfer decreases from (94 ± 5)% at (226 ± 11) K to (88 ± 5)% at (355 ± 8) K. (Table: 00-3, Note: 00-3, Evaluated: 10-6) [Back to Table](#)

B13. HO₂ + HO₂. The overall rate coefficient for this reaction is the sum of a pressure-independent bimolecular component and a pressure-dependent termolecular component. Two separate expressions are given for these rate coefficients. Both components contribute to the overall loss of HO₂ under atmospheric conditions and have negative temperature dependencies. This reaction also has a dependence on H₂O that needs to be included in atmospheric model calculations. Christensen et al.^{2,3} found that kinetic studies that used CH₃OH as an HO₂ radical precursor were possibly complicated by the formation of a weakly bound reactive HO₂-CH₃OH adduct, particularly important at low temperatures. The magnitude of the CH₃OH effect on the measured rate coefficients is dependent on the CH₃OH concentration and temperature in the particular study.

The recommended bimolecular and termolecular expressions for the HO₂ + HO₂ reaction were obtained from a global fit of the rate coefficient data that had negligible complications due to the presence of CH₃OH. The analysis included data obtained at low pressure (<30 Torr) from Thrush and Tyndall^{27,28} (7–20 Torr, 298–358 K), Simonaitis and Hecklen²¹ (5–770 Torr, 296 K), Sander¹⁹ (1 Torr, 298 K), Takacs and Howard^{24,25} (1–7

Torr, 252–391 K), Kurylo et al.¹³ (25–600 Torr, 298 K), and Tang et al.²⁶ (30 Torr, 253–323 K) and data obtained at higher pressure (>30 Torr) from Sander et al.²⁰ (100–700 Torr, 298 K), Simonaitis and Heicklen,²¹ Kurylo et al.,¹³ Christensen³ (100 Torr, 222–295 K), Kircher and Sander¹² (100–700 Torr, 230–420 K) (only data above 298 K were used in the analysis), and Maricq and Szenté¹⁶ (200 Torr, 210–365 K). The rate coefficient data obtained using transient UV absorption detection of HO₂^{12,13,16,20,21} were scaled to the currently recommended HO₂ absorption cross sections. Rate coefficient studies of Kurylo et al., Sander et al.,²⁰ and Kircher and Sander found little difference in the measured rate coefficient when N₂ or O₂ was used as the bath gas. The recommended termolecular expression applies to M = air. The experimental data is reproduced to within ±20% using the recommended parameters. The rate coefficient data reported by Maricq and Szenté are systematically 20% higher than the current recommendation. Systematic discrepancies also exist in the low-temperature rate coefficient data where the results from Christensen et al. are ~25% lower than the current recommendation at 222 K. Hamilton and Lii⁹ and Sander et al.²⁰ have reported the dependence of the rate coefficient on isotopic (H/D) substitution. Lightfoot et al.¹⁴ reported rate coefficients at atmospheric pressure over the temperature range 298–777 K that are in agreement with the recommended value at 298 K. This study indicates an upward curvature in the rate coefficient at temperatures above 500 K. A high temperature (750–1120 K) study by Hippler et al.¹⁰ confirms the strong curvature. The current recommendation does not account for the non-Arrhenius behavior and is valid only for temperatures below 500 K.

Stone and Rowley²² reported rate coefficient data at 760 Torr over the temperature range 236–309 K that were later shown by Christensen et al.² to be systematically overestimated due to the use of very high concentrations of CH₃OH. The Stone and Rowley²² data were not included in the present evaluation. The rate coefficient data and temperature dependence reported by Cox and Burrows⁴ is in general agreement with this recommendation. Data from Rozenshtein et al.¹⁸ are consistent with the low-pressure recommendation but they report no change in the rate coefficient with pressure up to 1 atm. Results reported by Thrush and Wilkinson²⁹ and Dobis and Benson⁶ are inconsistent with the recommendation.

The HO₂ + HO₂ reaction exhibits a dependence on H₂O concentration due to the formation of a weakly bound reactive HO₂•H₂O complex. English et al.⁷ report a bond energy of 6.9 kcal mol⁻¹ for the complex (also see Table 3). There are numerous studies of the rate coefficient H₂O dependence (Hamilton,⁸ Hohanadel et al.,¹¹ Hamilton and Lii,⁹ Cox and Burrows,⁴ DeMore,⁵ Lii et al.,¹⁵ Sander et al.,²⁰ Andersson et al.,¹ Stone and Rowley,²² English et al.,⁷ and Tang et al.²⁶) that are in good agreement. The effective rate coefficient in the presence of H₂O can be obtained by multiplying the recommended rate coefficient by the factor given by Lii et al.¹⁵ and Kircher and Sander:¹² $[1 + 1.4 \times 10^{-21} [\text{H}_2\text{O}] \exp(2200/T)]$.

The major reaction products at 300 K have been identified as H₂O₂ + O₂ by Su et al.,²³ Niki et al.,¹⁷ Sander et al.,²⁰ and Simonaitis and Heicklen.²¹

B14. $\text{HO}_2 + \text{HO}_2\text{-H}_2\text{O}$. The enhancement of the $\text{HO}_2 + \text{HO}_2$ reaction in the presence of H_2O vapor has been ascribed to the formation of a $\text{HO}_2\text{-H}_2\text{O}$ complex and the higher reactivity of the complex over that of HO_2 . The recommendation is based upon the studies of Kanno et al.^{1,2} who analyzed the enhancement of HO_2 decays in the presence of H_2O . Enhancement factors were obtained at 298, 325, and 350 K and a total pressure of 50 Torr N_2 . A pressure dependence of the rate coefficient has not been measured and a pressure independent value is recommended.

1.8 NO_x Reactions

1.8.1 Table 1C: NO_x Reactions

Reaction	Temperature Range of Exp. Data (K) ^a	A-Factor	E/R	k(298 K) ^b	f(298 K) ^c	g	Note
$O + NO \xrightarrow{M} NO_2$		(See Table 2-1)					
$O + NO_2 \rightarrow NO + O_2$	199–2300	5.1×10^{-12}	-210	1.04×10^{-11}	1.1	20	C 1
$O + NO_2 \xrightarrow{M} NO_3$		(See Table 2-1)					
$O + NO_3 \rightarrow O_2 + NO_2$	298–329	1.0×10^{-11}	0	1.0×10^{-11}	1.5	150	C 2
$O + N_2O_5 \rightarrow \text{products}$	223–300			$<3.0 \times 10^{-16}$			C 3
$O + HNO_3 \rightarrow OH + NO_3$	298			$<3.0 \times 10^{-17}$			C 4
$O + HO_2NO_2 \rightarrow \text{products}$	228–297	7.8×10^{-11}	3400	8.6×10^{-16}	3.0	750	C 5
$H + NO_2 \rightarrow OH + NO$	195–2000	4.0×10^{-10}	340	1.3×10^{-10}	1.3	300	C 6
$OH + NO \xrightarrow{M} HONO$		(See Table 2-1)

Shaded areas indicate changes or additions since JPL10-6.

^a Temperature range of available experimental data. This is not necessarily the range of temperature over which the recommended Arrhenius parameters are applicable. See the corresponding note for each reaction for such information.

^b Units are cm³ molecule⁻¹ s⁻¹.

^c f(298 K) is the uncertainty factor at 298 K. To calculate the uncertainty at other temperatures, use the expression:

$$f(T) = f(298 \text{ K}) \exp \left| g \left(\frac{1}{T} - \frac{1}{298} \right) \right|$$

Note that the exponent is an absolute value.

1.8.2 Notes: NO_x Reactions

- C1. O + NO₂.** The recommended values are based on the results of studies over a range of temperatures by Estupiñán et al.,³ Gierczak et al.,⁵ Ongstad and Birks,⁶ Slinger et al.,⁸ and Geers-Muller and Stuhl⁴ and the room temperature study of Paulson et al.⁷ In the most recent studies of Estupiñán et al.³ and Gierczak et al.,⁵ special emphasis was placed on accurate measurement of the NO₂ concentration and on measurements at low temperatures. The results of earlier studies by Davis et al.² and Bemand et al.¹ were not used in deriving the recommended values either because of possible complications from decomposition of NO₂ at higher temperatures or lack of direct NO₂ detection.

- C2. O + NO₃.** The recommendation is based on the study of Graham and Johnston¹ at 298 and 329 K. While limited in temperature range, the data indicate no temperature dependence. Furthermore, by analogy with the reaction of O with NO₂, it is assumed that this rate constant is independent of temperature. Clearly, temperature-dependence studies are needed.

C7. OH + NO₃. The recommendation is derived from an average of the results of Boodaghians et al.,² Mellouki et al.,³ Becker et al.,¹ and Mellouki et al.⁴ There are no temperature dependence data. The reaction products are probably HO₂ + NO₂.

C8. OH + HONO. The recommended rate expression is derived from the work of Jenkin and Cox,³ which supersedes the earlier room temperature study of Cox et al.² Results from the Burkholder et al.¹ suggest that the reaction may have a small negative temperature dependence.

(Table: 92-20, Note: 92-20, Evaluated: 92-20) [Back to Table](#)

C9. OH + HNO₃. The recent study of Brown et al.² furnishes the most comprehensive set of rate measurements for N₂ as the bath gas over a significant range of temperature (200–350 K) and pressure (20–500 Torr). They analyzed their results in terms of the mechanism proposed by Smith et al.,⁵ involving the formation of a bound, relatively long-lived HO•HNO₃ complex, as well as the direct reaction channel. Studies of the effects of isotopic substitution on the reactions OD + DNO₃, OH + DNO₃, OD + HNO₃, and ¹⁸OH + HNO₃ by Brown et al.¹ support this mechanism and suggest that the structure of the intermediate consists of a H-bonded six-membered ring. Thus, the P dependence can be represented by combining a low-pressure (bimolecular) limit, k₀, with a Lindemann-Hinshelwood expression for the p-dependence:

$$k([M], T) = k_0 + \frac{k_3[M]}{1 + \frac{k_3[M]}{k_2}} \quad \left\{ \begin{array}{l} k_0 = 2.4 \times 10^{-14} \exp\left(\frac{460}{T}\right) \\ k_2 = 2.7 \times 10^{-17} \exp\left(\frac{2199}{T}\right) \\ k_3 = 6.5 \times 10^{-34} \exp\left(\frac{1335}{T}\right) \end{array} \right\}$$

The coefficients k_3 and k_2 are the termolecular and high pressure limits for the “association” channel. The value of k at high pressures is the sum $k_0 + k_2$.

This expression for $k([M], T)$ and the values of the Arrhenius parameters for k_0 , k_2 , and k_3 derived by Brown et al.² for N_2 as the bath gas constitute the recommended values for this rate coefficient. These recommended values are derived from a fit to the data of Brown et al.,² Stachnik et al.,⁶ Devolder et al.,³ and Margitan and Watson.⁴

The reaction yield of NO_3 (per OH removed) is assumed to be unity at all temperatures for either reaction channel. These assumptions are supported by the isotopic studies of Brown et al.¹ and the theoretical calculations of Xia and Lin.⁷

C10. OH + HO_2NO_2 . The recommendation for both k at 298 K and the Arrhenius expression is based upon the data of Trevor et al.,⁵ Barnes et al.,¹ C. A. Smith et al.,⁴ and Barnes et al.² Trevor et al. studied this reaction over the temperature range 246–324 K and reported a temperature invariant value of $4.0 \times 10^{-12} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$, although a weighted least squares fit to their data yields an Arrhenius expression with an E/R value of $(193 \pm 193) \text{ K}$. In contrast, Smith et al. studied the reaction over the temperature range 240–300 K and observed a negative temperature dependence with an E/R value of $-(650 \pm 30) \text{ K}$. The early Barnes et al.¹ study was carried out only at room temperature and 1 Torr total pressure while their later study was performed in the pressure range 1–300 Torr N_2 and temperature range 268–295 K with no rate constant variation being observed. In addition, $k(298 \text{ K})$ derived in Barnes et al.¹ was revised upward in the later study from 4.1×10^{-12} to $5.0 \times 10^{-12} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ due to a change in the rate constant for the reference reaction. The values of k at 298 K from the four studies are in excellent agreement. An unweighted least squares fit to the data from the above-mentioned studies yields the recommended Arrhenius expression. The less precise value for k at 298 K reported by Littlejohn and Johnston³ is in fair agreement with the recommended value. The error limits on the recommended E/R are sufficient to encompass the results of both Trevor et al. and Smith et al. It should be noted that the values of k at 220 K deduced from the two studies differ by a factor of 2. Clearly, additional studies of k as a function of temperature and the identification of the reaction products are needed.

C11. OH + NH₃. The recommended value at 298 K is the average of the values reported by Stuhl,¹⁰ Smith and Zellner,⁸ Perry et al.,⁶ Silver and Kolb,⁷ Stephens,⁹ and Diau et al.² The values reported by Pagsberg et al.⁵ and Cox et al.¹ were not considered because these studies involved the analysis of a complex mechanism and the results are well outside the error limits implied by the above six direct studies. The results of Kurylo⁴ and Hack et al.³ were not considered because of their large discrepancies with the other direct studies (factors of 3.9 and 1.6 at room temperature, respectively). Because the Arrhenius plot displays considerable curvature, the temperature dependence is based only on the data below 300 K, i.e., the studies of Smith and Zellner⁸ and Diau et al.,² and the A-factor has been selected to fit the recommended room temperature value.

C12. HO₂ + NO. The recommendation for HO₂ + NO is based on the average of eight measurements of the rate constant at room temperature and below: Howard and Evenson,⁷ Leu,¹⁰ Howard,⁶ Hack et al.,⁵ Jemi-Alade and Thrush,⁹ Seeley et al.,¹² Bohn and Zetsch,² and Bardwell et al.¹ All of these are in quite good agreement. The results of Imamura and Washida⁸ were not considered due to the relatively large uncertainty limits reported in this study. An earlier study, Burrows et al.³ has been disregarded because of an error in the reference rate constant, $k(\text{OH} + \text{H}_2\text{O}_2)$. The room temperature study of Rozenshtein et al.¹¹ has also been disregarded due to an inadequate treatment of possible secondary reactions. The data of Glaschick-Schimpf et al.⁴ were not considered because of complications associated with the HO₂ detection method. The data of Thrush and Wilkinson¹³ were not considered because it is a relative rate study. The recommended Arrhenius parameters are obtained from a fit to all the data. The recommended value of $k(298 \text{ K})$ is obtained from the Arrhenius line.

C13. $\text{NO}_2^* + \text{H}_2\text{O}$. The reaction of NO_2 with H_2O to produce OH and HONO is endothermic by about 40 kcal mole⁻¹ (ground state reactants and products). However, absorption of light by NO_2 at wavelengths less than 718 nm can exceed the thermodynamic threshold if all the NO_2 internal energy is available for reaction. Crowley and Carl² photolyzed $\text{NO}_2/\text{H}_2\text{O}$ mixtures in the 430–450 nm spectral region and observed an OH action spectrum that mimicked the absorption features of NO_2 . Because the dependence of the OH signal on photolysis laser energy was second order, they suggested that two-photon absorption of NO_2 produced $\text{O}(^1\text{D})$ in their experiment which reacted with water vapor to produce OH . The energetic threshold for $\text{O}(^1\text{D})$ production is 488 nm. When they performed the same experiment with 532 nm photolysis, no OH production was observed giving an upper limit for the OH branching fraction (reactive vs. unreactive quenching) of 7×10^{-5} . Li et al.³ carried out laser pump/probe experiments at photolysis wavelengths between 560 and 640 nm in $\text{NO}_2/\text{H}_2\text{O}$ mixtures. In contrast to Crowley and Carl, they found significant OH production in this wavelength range. Their experiments showed a unity slope dependence of OH production on laser energy, suggesting a one-photon process. Overtone pumping was used to check for the presence of HONO and HNO_3 , which might be the source of the observed OH radicals. The rate constant for the $\text{NO}_2^* + \text{H}_2\text{O}$ reaction was determined to be $1.7 \times 10^{-13} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ for NO_2 excitation at 565, 590 and 612.5 nm with an overall uncertainty of $\pm 50\%$. This is large enough to have a significant impact on HO_x production in the troposphere. Carr et al.¹ performed a laser pump/probe experiment at 567.5 and 563.5 nm in $\text{NO}_2/\text{H}_2\text{O}$ mixtures. These experiments failed to detect OH formation, resulting in an upper limit of 6×10^{-5} for the reactive branching fraction.

Although this reaction is potentially important, in view of the disagreement in the published results, the Panel makes no recommendation on this reaction until additional credible studies are carried out.

C14. $\text{HO}_2 + \text{NO}_2$. Tyndall et al.¹ obtained an upper limit to the rate coefficient of $5 \times 10^{-16} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ based on static photolysis experiments with FTIR analysis at 296 K and 760 Torr of N_2 .

- (1) Tyndall, G. S.; Orlando, J. J.; Calvert, J. G. Upper limit for the rate coefficient for the reaction $\text{HO}_2 + \text{NO}_2 \rightarrow \text{HONO} + \text{O}_2$. *Environ. Sci. Technol.* **1995**, *29*, 202-206, doi:10.1021/es00001a026.

C15. $\text{HO}_2 + \text{NO}_3$. The recommendation for $k(298 \text{ K})$ is based on a weighted average of the data of Hall et al.,² Mellouki et al.,³ Becker et al.,¹ and Mellouki et al.⁴ There are insufficient data on which to base the temperature dependence of the rate coefficient. The measured branching ratios for the $\text{OH} + \text{NO}_2 + \text{O}_2$

channel range from 0.57 to 1.0. The most direct measurement is derived from the study of Mellouki et al.,⁴ which obtained a value of $1.0 \pm 0.0/-0.3$ at 298 K.

(Table: 94-26, Note: 94-26, Evaluated: 94-26) [Back to Table](#)

- (1) Becker, E.; Rahman, M. M.; Schindler, R. N. Determination of the rate constants for the gas phase reactions of NO_3 with H, OH and HO_2 radicals at 298 K. *Ber. Bunsenges. Phys. Chem.* **1992**, 96, 776-783.

C16. $\text{HO}_2 + \text{NH}_2$. There is a fairly good agreement on the value of k at 298 K between the direct study of Kurasawa and Lesclaux² and the relative studies of Cheskis and Sarkisov¹ and Pagsberg et al.³ The recommended value is the average of the values reported in these three studies. The identity of the products is not known; however, Kurasawa and Lesclaux suggest that the most probable reaction channels give either $\text{NH}_3 + \text{O}_2$ or $\text{HNO} + \text{H}_2\text{O}$ as products.

C17. $\text{N} + \text{O}_2$. The recommended expression is derived from a least squares fit to the data of Kistiakowsky and Volpi,⁴ Wilson,⁶ Becker et al.,² Westenberg et al.,⁵ Clark and Wayne,³ Winkler et al.,⁷ and Barnett et al.¹ $k(298 \text{ K})$ is derived from the Arrhenius expression and is in excellent agreement with the average of all of the room temperature determinations.

C18. $\text{N} + \text{O}_3$. The recommendation is based on the results of Barnett et al.¹ The value of $(1.0 \pm 0.2) \times 10^{-16} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ reported by Barnett et al. should probably be considered an upper limit rather than a determination. The low values reported by Barnett et al., Stief et al.,⁵ and Garvin and Broida³ cast doubt on the much faster rates reported by Phillips and Schiff⁴ and Chen and Taylor.²

C19. N + NO. The recommended temperature dependence is based on the discharge flow-resonance fluorescence studies of Wennberg and Anderson,¹⁴ and the discharge flow-resonance fluorescence and flash photolysis-resonance fluorescence studies of Lee et al.¹⁰ There is relatively poor agreement between these studies and the results of Clyne and McDermid,³ Kistiakowsky and Volpi,⁹ Herron,⁵ Phillips and Schiff,¹² Lin et al.,¹¹ Ishikawa et al.,⁷ Sugawara et al.,¹³ Cheah and Clyne,² Husain and Slater,⁶ Clyne and Ono,⁴ Brunning and Clyne,¹ and Jeoung et al.⁸

C20. N + NO₂. The recommendation for $k(298\text{ K})$ is from the discharge flow-resonance fluorescence study of Wennberg and Anderson.⁵ The latter study had significantly better sensitivity for $N(^4S)$ than the discharge flow-resonance fluorescence study of Clyne and Ono,² which obtained a value about four times smaller. The results of Husain and Slater³ and Clyne and McDermid¹ are not considered. The temperature dependence is obtained from the study of Wennberg and Anderson. In the latter study, atomic oxygen was shown to be the principal reaction product, in agreement with Clyne and McDermid. A recent study by Iwata et al.⁴ suggested an upper limit of $3.3 \times 10^{-13} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ for the corresponding reaction involving $N(^2D)$ and $N(^2P)$ atoms (sum of all reaction channels).

C21. $\text{NO} + \text{O}_3$. The recommended values are based on the results of studies over a range of temperatures by Birks et al.,² Lippmann et al.,⁵ Ray and Watson,⁸ Michael et al.,⁶ Borders and Birks,³ and Moonen et al.⁷ and the room temperature studies of Stedman and Niki¹⁰ and Bemand et al.¹ The six temperature-dependent studies were given equal weighting in the recommendation by averaging over the E/R 's from each individual data set. Following the Moonen et al. recommendation, the 200 K data point from their study has been excluded from the fit. All of the temperature dependence studies show some curvature in the Arrhenius plot at temperatures below 298 K. Increasing scatter between the data sets is evident at the lower temperatures. Clough and Thrush,⁴ Birks et al., Schurath et al.,⁹ and Michael et al. have reported individual Arrhenius parameters for the two primary reaction channels producing ground and excited molecular oxygen. C22. $\text{NO} + \text{NO}_3$. The recommendation is based on the studies of Hammer et al.,¹ Sander and Kircher,² and Tyndall et al.,³ which are in excellent agreement.

(Table: 92-20, Note: 92-20, Evaluated: 92-20) [Back to Table](#)

C23. $\text{NO}_2 + \text{O}_3$. The recommended expression is derived from a least squares fit to the data of Davis et al.,² Graham and Johnston,³ Huie and Herron,⁴ and Cox and Coker.¹ The data of Verhees and Adema⁶ and Stedman and Niki⁵ were not considered because of systematic discrepancies with the other studies.

- C24. $\text{NO}_2 + \text{NO}_3$.** The existence of the reaction channel forming $\text{NO} + \text{NO}_2 + \text{O}_2$ has not been firmly established. However, studies of N_2O_5 thermal decomposition that monitor NO_2 (Daniels and Johnston;³ Johnston and Tao;⁵ Cantrell et al.¹) and NO (Hjorth et al.⁴ and Cantrell et al.²) require reaction(s) that decompose NO_3 into $\text{NO} + \text{O}_2$. The rate constant from the first three studies is obtained from the product kK_{eq} , where K_{eq} is the equilibrium constant for $\text{NO}_2 + \text{NO}_3 \rightarrow \text{N}_2\text{O}_5$, while for the latter two studies the rate constant is obtained from the ratio $k/k(\text{NO} + \text{NO}_3)$, where $k(\text{NO} + \text{NO}_3)$ is the rate constant for the reaction $\text{NO} + \text{NO}_3 \rightarrow 2\text{NO}_2$. Using K_{eq} and $k(\text{NO} + \text{NO}_3)$ from this evaluation, the rate expression that best fits the data from all five studies is $4.5 \times 10^{-14} \exp(-1260/T) \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ with an overall uncertainty factor of 2. - C26. $\text{NH}_2 + \text{O}_2$.** This reaction has several product channels which are energetically possible, including $\text{NO} + \text{H}_2\text{O}$ and $\text{HNO} + \text{OH}$. With the exception of the studies of Hack et al.² and Jayanty et al.³ and several studies at high temperature, there is no evidence for a reaction. The following upper limits have been measured ($\text{cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$): 3×10^{-18} (Lesclaux and Demissy⁴), 8×10^{-15} (Pagsberg et al.⁷), 1.5×10^{-17} (Cheskis and Sarkisov¹), 3×10^{-18} (Lozovsky et al.⁵), 1×10^{-17} (Patrick and Golden⁸) and 7.7×10^{-18} (Michael et al.⁶) and 6×10^{-21} (Tyndall et al.⁹). The recommendation is based on the study of Tyndall et al., which was sensitive to reaction paths leading to the products NO , NO_2 , and N_2O . The reaction forming NH_2O_2 cannot be ruled out, but is apparently not important in the atmosphere. (Table: 92-20, Note: 92-20, Evaluated: 92-20) [Back to Table](#)

C27. $\text{NH}_2 + \text{O}_3$. There is poor agreement among the recent studies of Cheskis et al.,² $k(298) = 1.5 \times 10^{-13} \text{ cm}^3 \text{ s}^{-1}$, Patrick and Golden,⁵ $k(298 \text{ K}) = 3.25 \times 10^{-13} \text{ cm}^3 \text{ s}^{-1}$, Hack et al.,³ $1.84 \times 10^{-13} \text{ cm}^3 \text{ s}^{-1}$, Bulatov et al.,¹ $1.2 \times 10^{-13} \text{ cm}^3 \text{ s}^{-1}$, and Kurasawa and Lesclaux,⁴ $0.63 \times 10^{-13} \text{ cm}^3 \text{ s}^{-1}$. The very low value of Kurasawa and Lesclaux may be due to regeneration of NH_2 from secondary reactions (see Patrick and Golden), and it is disregarded here. The discharge flow value of Hack et al. is nearly a factor of two less than the recent Patrick and Golden flash photolysis value. The large discrepancy between Bulatov et al. and Patrick and Golden eludes explanation. The recommendation is the $k(298 \text{ K})$ average of these four studies, and E/R is an average of Patrick and Golden (1151 K) with Hack et al. (710 K).

C28. $\text{NH}_2 + \text{NO}$. The recommended value for k at 298 K is the average of the values reported by Lesclaux et al.,¹¹ Hancock et al.,⁹ Sarkisov et al.,¹³ Stief et al.,¹⁷ Andresen et al.,¹ Whyte and Phillips,¹⁹ Dreier and Wolfrum,⁵ Atakan et al.,² Wolf et al.,²⁰ Diau et al.,³ and Imamura and Washida.¹⁰ The results of Gordon et al.,⁷ Gehring et al.,⁶ Hack et al.,⁸ and Silver and Kolb¹⁴ were not considered because they lie at least 2 standard deviations from the average of the previous group. The results tend to separate into two groups. The flash photolysis results average $1.8 \times 10^{-11} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ (except for the pulse radiolysis study of Gordon et al.), while those obtained using the discharge flow technique average $0.9 \times 10^{-11} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$. The apparent discrepancy cannot be due simply to a pressure effect as the pressure ranges of the flash photolysis and discharge flow studies overlapped and none of the studies observed a pressure dependence for k . Whyte and Phillips have suggested that the difference may be due to decomposition of the adduct NH_2NO , which occurs on the timescale of the flow experiments, but not the flash experiments. There have been many studies of the temperature dependence but most have investigated the regime of interest to combustion and only two have gone below room temperature (Hack et al. from 209–505 K and Stief et al. from 216–480 K. Each study reported k to decrease with increasing temperature. The recommended temperature dependence is taken from a fit to the Stief et al. data at room temperature and below. The reaction proceeds along a complex potential energy surface, which results in product branching ratios that are strongly dependent on temperature. *Ab initio* calculations by Walch¹⁸ show the existence of four saddle points in the potential surface leading to $\text{N}_2 + \text{H}_2\text{O}$ without a reaction barrier. Elimination to form $\text{OH} + \text{HN}_2$ can occur at any point along the surface. While results from early studies on the branching ratio for OH formation differ significantly, the most recent studies (Hall et al.,⁴ Dolson,⁴ Silver and Kolb,¹⁵ Atakan et al.,² Stephens et al.,¹⁶ and Park and Lin¹²) agree on a value around 0.1 at 300 K, with $\text{N}_2 + \text{H}_2\text{O}$ making up the balance.

C29. $\text{NH}_2 + \text{NO}_2$. There have been four studies of this reaction (Hack et al.;¹ Kurasawa and Lesclaux;² Whyte and Phillips;³ and Xiang et al.⁴). There is very poor agreement among these studies both for k at 298 K (factor of 2.3) and for the temperature dependence of k ($T^{-3.0}$ and $T^{-1.3}$). The recommended values of k at 298 K and the temperature dependence of k are averages of the results reported in these four studies. Hack et al. have shown that the predominant reaction channel (>95%) produces $\text{N}_2\text{O} + \text{H}_2\text{O}$. Just as for the $\text{NH}_2 + \text{NO}$ reaction, the data for this reaction seem to indicate a factor of two discrepancy between flow and flash techniques, although the database is much smaller.

- C34. N₂(A,v) + O₂.** Rate constants for the overall reaction for the $v = 0, 1$ and 2 vibrational levels of $\text{N}_2(\text{A})$ have been made by Dreyer et al.,³ Zipf,⁹ Piper et al.,⁷ Iannuzzi and Kaufman,⁶ Thomas and Kaufman,⁸ and De Sousa et al.² The results of these studies are in relatively good agreement. The recommended values are (2.5 ± 0.4) , (4.0 ± 0.6) , and $(4.5 \pm 0.6) (10^{-12} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1})$, from the work of De Sousa et al. The only temperature dependence data are from De Sousa et al., who obtained $k(T,v) = k(v,298 \text{ K})(T/300)^{0.55}$ for $v = 0,1,2$. The observation of high N_2O production initially reported by Zipf⁹ has not been reproduced by other groups, and the branching ratio for this channel is probably less than 0.02 (Iannuzzi et al.,⁵ Black et al.,¹ De Sousa et al.,² and Fraser and Piper⁴). The branching ratios for the other channels are poorly established, although there is strong evidence for the formation of both $\text{O}(^3\text{P})$ and $\text{O}_2(\text{B}^3\Sigma_u^-)$. C35. $N_2(A,v) + O_3$. The only study is that of Bohmer and Hack,¹ who obtained 298 K rate constants of 4.1 ± 1.0 , 4.1 ± 1.2 , 8.0 ± 2.3 , and 10 ± 3.0 ($10^{-11} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$) for the $v = 0-3$ vibrational levels of $N_2(A)$, respectively. This study determined that the NO channel accounts for about 20% of the reaction products. (Table: 94-26, Note: 94-26, Evaluated: 94-26) [Back to Table](#)

1.9 Reactions of Organic Compounds

1.9.1 Table 1D: Reactions of Organic Compounds

Reaction	Temperature Range of Exp. Data (K) ^a	A-Factor	E/R	k(298 K) ^b	f(298 K) ^c	g	Note
O + CH ₃ → products	259–341	1.1×10 ⁻¹⁰	0	1.1×10 ⁻¹⁰	1.3	250	D 1
O + HCN → products	469–900	1.0×10 ⁻¹¹	4000	1.5×10 ⁻¹⁷	10	0	D 2
O + C ₂ H ₂ → products	(See Note)	3.0×10 ⁻¹¹	1600	1.4×10 ⁻¹³	1.3	250	D 3
O + H ₂ CO → products	250–748	3.4×10 ⁻¹¹	1600	1.6×10 ⁻¹³	1.25	250	D 4
O + CH ₃ CHO → CH ₃ CO + OH	298–475	1.8×10 ⁻¹¹	1100	4.5×10 ⁻¹³	1.25	200	D 5
O ₂ + HOCO → HO ₂ + CO ₂	298			2×10 ⁻¹² (See Note)	2		D 6
O ₃ + C ₂ H ₂ → products	243–323	1.0×10 ⁻¹⁴	4100	1.0×10 ⁻²⁰	3	500	D 7
O ₃ + C ₂ H ₄ → products	178–373	1.2×10 ⁻¹⁴	2630	1.7×10 ⁻¹⁸	1.25	100	D 8
O ₃ + C ₃ H ₆ → products	183–362	6.5×10 ⁻¹⁵	1900	1.1×10 ⁻¹⁷	1.15	200	D 9
O ₃ + CH ₂ =C(CH ₃)CHO → products	240–324	1.5×10 ⁻¹⁵	2110	1.3×10 ⁻¹⁸	1.1	200	D10
O ₃ + CH ₃ C(O)CH=CH ₂ → products	240–324	8.5×10 ⁻¹⁶	1520	5.2×10 ⁻¹⁸	1.15	100	D11
O ₃ + CH ₂ =C(CH ₃)CH=CH ₂ → products	242–353	1.1×10 ⁻¹⁴	2000	1.3×10 ⁻¹⁷	1.1	200	D12
OH + CO → Products		(See Table 2-1)					D13
OH + CH ₄ → CH ₃ + H ₂ O	178–2025	2.45×10 ⁻¹²	1775	6.3×10 ⁻¹⁵	1.1	100	D14
OH + ¹³ CH ₄ → ¹³ CH ₃ + H ₂ O		See Note					D15
OH + CH ₃ D → products	249–420	3.5×10 ⁻¹²	1950	5.0×10 ⁻¹⁵	1.15	200	D16
OH + H ₂ CO → H ₂ O + HCO	228–2500	5.5×10 ⁻¹²	–125	8.5×10 ⁻¹²	1.15	50	D17
OH + CH ₃ OH → products	210–1350	2.9×10 ⁻¹²	345	9.1×10 ⁻¹³	1.10	60	D18
OH + CH ₃ OOH → products	203–423	3.8×10 ⁻¹²	–200	7.4×10 ⁻¹²	1.4	150	D19
OH + HC(O)OH → products	296–445	4.0×10 ⁻¹³	0	4.0×10 ⁻¹³	1.2	100	D20
OH + HC(O)C(O)H → products	210–390	1.15×10 ⁻¹¹	0	1.15×10 ⁻¹¹	1.5	200	D21
OH + HOCH ₂ CHO → products	233–362	1.1×10 ⁻¹¹	0	1.1×10 ⁻¹¹	1.2	200	D22
OH + HCN → products	296–563	1.2×10 ⁻¹³	400	3.1×10 ⁻¹⁴	3	150	D23
OH + C ₂ H ₂ $\xrightarrow{\text{M}}$ products		(See Table 2-1)					

Reaction	Temperature Range of Exp. Data (K) ^a	A-Factor	E/R	k(298 K) ^b	f(298 K) ^c	g	Note
OH + C ₂ H ₄ $\xrightarrow{M}$ products		(See Table 2-1)					
OH + C ₂ H ₆ → H ₂ O + C ₂ H ₅	226–2000	7.66×10 ⁻¹²	1020	2.5×10 ⁻¹³	1.07	50	D24
OH + CH ₃ CHO → products	202–900	4.63×10 ⁻¹²	–350	1.5×10 ⁻¹¹	1.05	20	D25
OH + CH ₃ CH ₂ OH → products	216–498	3.35×10 ⁻¹²	0	3.35×10 ⁻¹²	1.05	20	D26
OH + CH ₃ C(O)OH → products	229–802	3.15×10 ⁻¹⁴	–920	6.9×10 ⁻¹³	1.15	100	D27

Shaded areas indicate changes or additions since JPL10-6. Italicized *blue* entries denote estimates.

^a Temperature range of available experimental data. This is not necessarily the range of temperature over which the recommended Arrhenius parameters are applicable. See the corresponding note for each reaction for such information.

^b Units are cm³ molecule⁻¹ s⁻¹.

^c *f*(298 K) is the uncertainty factor at 298 K. To calculate the uncertainty at other temperatures, use the expression:

$$f(T) = f(298 \text{ K}) \exp \left| g \left(\frac{1}{T} - \frac{1}{298} \right) \right|$$

Note that the exponent is an absolute value.

1.9.2 Notes: Reactions of Organic Compounds

- D1. O + CH₃.** The recommended $k(298\text{ K})$ is the weighted average of the measurements by Washida and Bayes,³ Washida,² and Plumb and Ryan.¹ The E/R value is based on the results of Washida and Bayes,³ who found k to be independent of temperature between 259 and 341 K.

 - (3) Washida, N.; Bayes, K. D. The reactions of methyl radicals with atomic and molecular oxygen. *Int. J. Chem. Kinet.* **1976**, 8, 777-794.
- D2. O + HCN.** Because it is a very slow reaction, there are no studies of this reaction below 450 K. Davies and Thrush¹ studied this reaction between 469 and 574 K while Perry and Melius³ studied it between 540 and 900 K. Results of Perry and Melius are in agreement with those of Davies and Thrush. Our recommendation is based on these two studies. The higher-temperature ($T > 1000\text{ K}$) combustion-related studies of Roth et al.,⁴ Szekely et al.,⁵ and Louge and Hanson² have not been considered. This reaction has two reaction pathways: $\text{O} + \text{HCN} \rightarrow \text{H} + \text{NCO}$, $\Delta H = -2\text{ kcal/mol}$ (k_a); and $\text{O} + \text{HCN} \rightarrow \text{CO} + \text{NH}$ (k_b), $\Delta H = -36\text{ kcal/mol}$. The branching ratio k_a/k_b for these two channels has been measured to be ~ 2 at $T = 860\text{ K}$. The branching ratio at lower temperatures, which is likely to vary significantly with temperature, is unknown.

- D3. O + C₂H₂.** The value at 298 K is an average of ten measurements (Arrington et al.,² Sullivan and Warneck,⁸ Brown and Thrush,³ Hoyermann et al.,^{4,5} Westenberg and deHaas,¹⁰ James and Glass,⁶ Stuhl and Niki,⁷ Westenberg and deHaas,¹¹ and Aleksandrov et al.¹). There is reasonably good agreement among these studies. Arrington et al.² did not observe a temperature dependence, an observation that was later shown to be erroneous by Westenberg and deHaas.¹⁰ Westenberg and deHaas,¹⁰ Hoyermann et al.,⁵ and Aleksandrov et al.¹ are the only authors who have measured the temperature dependence below 500 K. Westenberg and deHaas observed a curved Arrhenius plot at temperatures higher than 450 K. In the range 194–450 K, Arrhenius behavior provides an adequate description and the E/R obtained by a fit of the data from these three groups in this temperature range is recommended. The A -factor was calculated to reproduce $k(298\text{ K})$. This reaction can have two sets of products, i.e., C₂HO + H or CH₂ + CO. Under molecular beam conditions C₂HO has been shown to be the major product. The study by Aleksandrov et al. using a discharge flow-resonance fluorescence method (under undefined pressure conditions) indicates that the C₂HO + H channel contributes no more than 7% to the net reaction at 298 K, while a similar study by Vinckier et al.⁹ suggests that both CH₂ and C₂HO are formed.

D4. O + H₂CO. The recommended values for A, E/R and k(298 K) are the averages of those determined by Klemm³ (250 to 498 K) using flash photolysis-resonance fluorescence, by Klemm et al.⁴ (298 to 748 K) using discharge flow-resonance fluorescence, and Chang and Barker¹ (296 to 436 K) using discharge flow-mass spectrometry techniques. All three studies are in good agreement. The k(298 K) value is also consistent with the results of Niki et al.,⁶ Herron and Penzhorn,² and Mack and Thrush.⁵ Although the mechanism for O + H₂CO has been considered to be the abstraction reaction yielding OH + HCO, Chang and Barker suggest that an additional channel yielding H + HCO₂ may be occurring to the extent of 30% of the total reaction. This conclusion is based on an observation of CO₂ as a product of the reaction under conditions where reactions such as O + HCO → H + CO₂ and O + HCO → OH + CO apparently do not occur. This interesting suggestion needs independent confirmation.

D5. O + CH₃CHO. The recommended k(298 K) is the average of three measurements by Cadle and Powers,² Mack and Thrush,³ and Singleton et al.,⁴ which are in good agreement. Cadle and Powers and Singleton et al. studied this reaction as a function of temperature between 298 and 475 K and obtained very similar Arrhenius parameters. The recommended E/R value was obtained by considering both sets of data. This reaction is known to proceed via H-atom abstraction (Mack and Thrush,³ Avery and Cvetanovic,¹ and Singleton et al.⁴). (Table: 87-41, Note: 87-41, Evaluated 87-41) [Back to Table](#)

D6. O₂ + HOCO. HOCO is produced by the association of OH with CO (See Table 2). The rate coefficient for the reaction of O₂ with HOCO has been measured by Petty et al.² and Nolte et al.¹ and the recommendation is based on these measurements. There are no reports on the temperature dependence of this reaction; however, the value at 298 K would be appropriate for all atmospheric conditions. The products of this reaction are HO₂, as shown by Nolte et al., and CO₂, as seen in numerous previous studies where it has been known to be the product of the reaction of OH with CO in air.

D7. $\text{O}_3 + \text{C}_2\text{H}_2$. The database for this reaction is not well established. Room temperature measurements (Cadle and Schadt,² DeMore,³ DeMore,⁴ Stedman and Niki,⁷ Pate et al.,⁶ and Atkinson and Aschmann¹) disagree by as much as an order of magnitude. It is probable that secondary reactions involving destruction of ozone by radical products resulted in erroneously high values for the rate constants in several of the previous measurements. The present recommendation for $k(298\text{ K})$ is based on the room temperature value of Atkinson and Aschmann,¹ which is the lowest value obtained and therefore perhaps the most accurate. The temperature dependence is estimated, based on an assumed A-factor of $10^{-14}\text{ cm}^3\text{ molecule}^{-1}\text{ s}^{-1}$ similar to that for the $\text{O}_3 + \text{C}_2\text{H}_4$ reaction and corresponding to the expected five-membered ring structure for the transition state (DeMore^{3,4}). Further studies, particularly of the temperature dependence, are needed. Major products in the gas phase reaction are CO, CO_2 , and HCOOH , and chemically-activated formic anhydride has been proposed as an intermediate of the reaction (DeMore,⁴ and DeMore and Lin⁵). The anhydride intermediates in several alkyne ozonations have been isolated in low temperature solvent experiments (DeMore and Lin⁵). (Table: 90-1, Note: 90-1, Evaluated 90-1) [Back to Table](#)

D9. $\text{O}_3 + \text{C}_3\text{H}_6$. The rate constant of this reaction is well established over the temperature range 185 to 360 K. The present recommendation is based largely on the data of Herron and Huie,⁵ in the temperature range 235–362 K. (Note that a typographical error in Table 2 of that paper improperly lists the lowest temperature as 250 K, rather than the correct value, 235 K.) The recommended Arrhenius expression agrees within 25% with the low temperature (185–195 K) data of DeMore,⁴ and is consistent with, but slightly higher (about 10%) than the data of Treacy et al.¹⁰ and slightly lower (about 40%) than the data of Adeniji et al.¹ in the temperature range 260–294 K. Room temperature measurements of Cox and Penkett,³ Stedman et al.,⁹ Japar et al.,^{6,7} and Atkinson et al.² and Neeb and Moorgat⁸ are in good agreement (10% or better) with the recommendation.

D10. $\text{O}_3 + \text{CH}_2=\text{C}(\text{CH}_3)\text{CHO}$. The recommended E/R is based on the single temperature dependence study by Treacy et al.⁷ The recommended 298 K rate constant is obtained from an unweighted fit to $\ln k = \ln A - E/RT$ of the ambient temperature results of Atkinson et al.,² Grosjean and Grosjean,⁴ Kamens et al.,⁵ Neeb et al.,⁶ and Treacy et al.⁷ in conjunction with the recommended E/R. While OH was scavenged only in the studies of Grosjean and Grosjean and Neeb et al., the studies where OH was not scavenged report results that agree well with the studies where OH was scavenged. By monitoring the production of cyclohexanone + cyclohexanol under conditions where OH was >95% scavenged by cyclohexane, Aschmann et al.¹ report an upper limit OH yield of 20^{+10}_{-13} percent. Ozone + alkene reactions proceed via initial formation of a primary ozonide that decomposes to a carbonyl compound plus a Criegee biradical with two different carbonyl/Criegee pairs produced (depending on which O–O bond cleaves); the Criegee biradical/carbonyl pairs produced in this case are $\text{CH}_3\text{C}(\text{O})\text{CHO}$ (methyl glyoxal) + $\bullet\text{CH}_2\text{OO}\bullet$ and $\text{H}_2\text{CO} + \text{CH}_3\text{C}(\bullet\text{OO})\text{CHO}$. Grosjean et al.³ report carbonyl product yields to be 58% $\text{CH}_3\text{C}(\text{O})\text{CHO}$ and 12% H_2CO .

D12. $\text{O}_3 + \text{CH}_2=\text{C}(\text{CH}_3)\text{CH}=\text{CH}_2$. The recommended E/R is based on an unweighted fit to the temperature-dependent rate constants reported by Khamaganov and Hites¹³ to $\ln k = \ln A - E/RT$, while the recommended A-factor is based on the ambient temperature rate constants reported by Greene and Atkinson,⁶ Grosjean et al.,⁷ Grosjean and Grosjean,⁸ Neeb and Moortgat,¹⁶ Klawatsch-Carrasco et al.,¹⁴ and Karl et al.¹² In all of the above studies, measures were taken to prevent secondary consumption of reactants by OH radicals, which are known to be generated in ozone + alkene reactions. Results from early studies by Adeniji et al.,¹ Atkinson et al.,³ and Treacy et al.,¹⁹ while in reasonable agreement with other studies, are not used to arrive at the recommendation because OH radicals were not scavenged in those studies. The Arrhenius parameters reported by Avzianova and Ariya⁴ are not accepted because of inconsistencies in their paper that the authors were unable to resolve (private communication from Ariya). Donahue et al.⁵ have directly detected OH as a product of the O_3 + isoprene reaction, and OH yields have been reported in a number of studies where OH production was monitored indirectly by following the loss of an OH scavenger or the production of a product of an OH + scavenger reaction.^{2,9,10,15-18} At room temperature and atmospheric pressure of air, reported OH yields from seemingly careful studies range from 0.19 to 0.53 with an average value of 0.32. The chemical pathways leading to OH production are too complex to discuss in this note; the interested reader is referred to a review article by Johnson and Marston.¹¹ As discussed by Johnson and Marston, the reaction proceeds via initial formation of a primary ozonide that decomposes to a carbonyl compound plus a Criegee biradical with several different carbonyl/Criegee pairs produced; the Criegee biradicals can react unimolecularly from a

chemically activated state or be collisionally deactivated and live long enough to undergo bimolecular reactions under atmospheric conditions.

D13. OH + CO. See note for the OH + CO reaction in Section 2.

[Back to Table](#)

D14. OH + CH₄. This reaction has been extensively studied. The most recent data are from Vaghjiani and Ravishankara,⁸ Saunders et al.,⁶ Finlayson-Pitts et al.,³ Dunlop and Tully,² Mellouki et al.,⁵ and Gierczak et al.,⁴ who measured the absolute rate coefficients for this reaction using discharge flow and pulsed photolysis techniques. Sharkey and Smith⁷ have reported a high value ($7.7 \times 10^{-15} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$) for $k(298 \text{ K})$, and this value has not been considered here. The current recommendation for $k(298 \text{ K})$ was derived from the results of Vaghjiani and Ravishankara, Dunlop and Tully, Saunders et al., Mellouki et al., Finlayson-Pitts et al., and Gierczak et al. The temperature dependence of this rate coefficient has been measured by Vaghjiani and Ravishankara (223–420 K), Dunlop and Tully (above 298 K), Finlayson-Pitts et al. (278–378 K), and

Mellouki et al. (233–343 K). Gierczak et al. have extended the measurements of k to 195 K, and it appears that the rate coefficient does not strictly follow an Arrhenius expression. The recommended E/R was obtained from these results using data below 300 K.

A more accurate representation of the rate constant as a function of temperature is obtained by using the three-parameter expression: $k(T) = 2.80 \times 10^{-14} T^{0.667} \exp(-1575/T) \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$. This three-parameter fit may be preferred for lower stratosphere and upper troposphere calculations. A report on this rate coefficient by Bonard et al.¹ agrees very well with the value recommended here.

D15. OH + ¹³CH₄. This reaction has been studied relative to the OH + CH₄ reaction, since the ratio of the rate coefficients is the quantity needed for quantifying methane sources. Rust and Stevens,³ Davidson et al.,² and Cantrell et al.¹ have measured k_{12}/k_{13} at 298 K to be 1.003, 1.010, and 1.0055, respectively. Cantrell et al.'s data supersede the results of Davidson et al. The recommended value of 1.005 ± 0.002 is based on the results of Rust and Stevens and Cantrell et al. Cantrell et al. find k_{12}/k_{13} to be independent of temperature between 273 and 353 K.

D16. OH + CH₃D. The rate coefficient for this reaction has been measured between 249 and 422 K using a pulsed laser photolysis-laser induced fluorescence system by Gierczak et al.³ The recommended values of $k(298 \text{ K})$ and E/R are from this study. The recommendation agrees within about 10% at 298 K with the rate constant measured by DeMore¹ in a relative rate study over the temperature range 298–360 K. The difference, while small in an absolute sense, is nevertheless significant for the isotopic fractionation of atmospheric CH₃D and CH₄ by OH. An earlier result of Gordon and Mulac⁴ at 416 K is in good agreement with the extrapolated data of both of these determinations. However, that measurement has not been explicitly included in this recommendation because the experiments were carried out at higher temperatures and therefore are less applicable to the atmosphere. The rate coefficients for the reactions of OH with other deuterated methanes have also been measured (Dunlop and Tully,² Gierczak et al.,⁵ Gordon and Mulac⁴).

D17. OH + H₂CO. The value for k(298 K) is the average of those determined by Niki et al.,⁶ Atkinson and Pitts,¹ Stief et al.,⁹ Yetter et al.,¹¹ Temps and Wagner,¹⁰ and Sivakumaran et al.⁷ The value reported by Morris and Niki³ is expected to be superseded by the later report of Niki et al.,⁶ although it agrees within the stated uncertainty. There are two relative values that are not in agreement with the recommendations. The value of Niki et al.⁴ relative to the OH + C₂H₄ reaction is higher, while the value of Smith⁸ relative to the OH + OH reaction is lower. The later report of Niki et al.⁶ is assumed to supersede the earlier rate constant. The rate coefficients reported by Zabarnick et al.¹² at and above 298 K are consistently higher than those recommended here, but overlap within the combined uncertainty. The temperature dependence was calculated from the data of Stief et al. obtained below 298 K and from the data of Sivakumaran et al. below 330 K after normalizing the results of both studies to k(298 K) recommended here. There is a clear indication that the Arrhenius plot of this rate coefficient is curved with a positive activation energy at temperatures above ~330 K. It is therefore important that the recommended rate coefficients be used only in the 200-300 K temperature range. The abstraction reaction shown in the table is the major channel (Temps and Wagner,¹⁰ Niki et al.⁵); other channels may contribute to a small extent (Horowitz et al.²). There is no indication that this rate coefficient is pressure dependent at atmospheric pressures and temperatures.

D18. OH + CH₃OH. The recommended value for $k(298\text{ K})$ is the average of direct studies by Overend and Paraskevopoulos,¹⁰ Ravishankara and Davis,¹² Hagele et al.,⁴ Meier et al.,⁹ McCaulley et al.,⁸ Wallington and Kurylo,¹⁴ Hess and Tully,⁵ Jimenez et al.,⁶ and Dillon et al.³ When these measurements were not at exactly 298 K, their values were recalculated for 298 K by using the E/R recommended here. Indirect measurements by Campbell et al.,² Barnes et al.,¹ Tuazon et al.,¹³ Picquet et al.,¹¹ and Klopffer et al.⁷ are in good agreement with the recommended value. The temperature dependence of k has been measured by Hagele et al., Meier et al., Greenhill and O'Grady, Wallington and Kurylo, Hess and Tully, Jimenez et al., and Crowley et al. The recommended value of E/R was calculated using the results obtained at temperature below 330 K by Wallington and Kurylo, Meier et al., Hess and Tully, Jimenez et al., and Crowley et al. The results of Greenhill and O'Grady are in reasonable agreement with the recommendation at and above 298 K, but are clearly lower than the recommendation below 298 K. Hess and Tully report a curved Arrhenius plot over the temperature range 298–1000 K, while Meier et al. did not observe such a curvature. This reaction has two pathways: abstraction of the H-atom from the methyl group to give CH₂OH + H₂O or from the OH group to give CH₃O + H₂O. The results of Hagele et al., Meier et al., and Hess and Tully suggest that H abstraction from the methyl group to give CH₂OH + H₂O is the dominant channel below room temperature. At 298 K, for example, the branching ratio for the formation of CH₂OH is about 0.85 and increases as the temperature decreases. In the Earth's atmosphere, the eventual products of OH + CH₃OH reaction are the same for both reaction channels: CH₂O and HO₂.

D19. OH + CH₃OOH. The recommended value for $k(298\text{ K})$ is the average of the rate coefficients measured by Niki et al.¹ and Vaghjiani and Ravishankara,² which differ by nearly a factor of two. Niki et al. measured the rate coefficient relative to that for OH with C₂H₄ ($= 8.0 \times 10^{-12} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$) by monitoring CH₃OOH disappearance using an FTIR system. Vaghjiani and Ravishankara monitored the disappearance of OH, OD, and ¹⁸OH in excess CH₃OOH in a pulsed photolysis-LIF system. They measured k between 203 and 423 K and report a negative activation energy with E/R = -190 K; the recommended E/R is based on their results. The reaction of OH with CH₃OOH occurs via abstraction of H from the oxygen end to produce the CH₃OO

radical and from the CH₃ group to produce the CH₂OOH radical, as originally proposed by Niki et al. and confirmed by Vaghjiani and Ravishankara. CH₂OOH is unstable and falls apart to CH₂O and OH within a few microseconds. The possible reaction of CH₂OOH with O₂ is unimportant under atmospheric conditions (Vaghjiani and Ravishankara). The recommended branching ratios are,

(from Vaghjiani and Ravishankara) and are nearly independent of temperature.

D20. OH + HC(O)OH. The recommended value of k(298 K) is the average of those measured by Zetzsch and Stuhl,⁵ Wine et al.,⁴ Jolly et al.,² Dagaut et al.,¹ and Singleton et al.³ The temperature dependence of k has been studied by Wine et al. and by Singleton et al., who observed k to be essentially independent of T. Wine et al. found the rate coefficient for the OH + HC(O)OH reaction to be the same as that for OH + DC(O)OH reaction. Jolly et al. found the formic acid dimer to be unreactive toward OH, i.e., abstraction of the H atom attached to C was not the major pathway for the reaction. A comprehensive study of Singleton et al. showed that reactivity of HC(O)OH is essentially the same as that of DC(O)OH, but DC(O)OD reacts much slower than HC(O)OH and DC(O)OH. These observations show that the reaction proceeds via abstraction of the acidic H atom. Wine et al. and Jolly et al. also found that H atoms are produced in the reaction, which is consistent with the formation of HC(O)O, which would rapidly fall apart to CO₂ and H. End product studies are also consistent with the formation of CO₂ and H₂O in this reaction (Singleton et al.³). The products of this reaction would be mostly HC(O)O and H₂O. The fate of HC(O)O in the atmosphere will be to give HO₂ either directly via reaction with O₂ or via thermal decomposition to H atom, which adds to O₂.

Wine et al. have suggested that, in the atmosphere, the formic acid could be hydrogen bonded to a water molecule and its reactivity with OH could be lowered because the hydrogen bonded water would obstruct the abstraction of the H atom. This suggestion needs to be checked.

D21. OH + HC(O)C(O)H. The only available data are from the 298 K relative rate study of Plum et al.¹ and the results are recommended here. Because the rate coefficient is so large, it is unlikely to have a substantial temperature dependence and an E/R of zero is recommended. This reaction is expected to proceed via H-abstraction to yield H₂O, CO and HCO.

(Table: 06-2, Note: 06-2, Evaluated 06-2) [Back to Table](#)

- (1) Plum, C. N.; Sanhueza, E.; Atkinson, R.; Carter, W. P. L.; Pitts, J. N., Jr. OH radical rate constant and photolysis rates of α-dicarbonyls. *Environ. Sci. Technol.* **1983**, *17*, 479-484.

D22. OH + HOCH₂CHO. The available data are from relative rate studies at 298 K (Bacher et al.,¹ Niki et al.,³ and Mellouki et al.²). The recommendation is based on all these studies, which are in good agreement. Because the rate coefficient is very large, it is unlikely to have a substantial temperature dependence.

Therefore, we recommend an E/R of zero. There are three possible sites for H-abstraction: the alcohol group, the CH₂ group and the carbonyl group. Of these, the likely pathways for abstraction are from the latter two sites:

Niki et al. have shown that the branching ratio for channel (b) is 0.8 and for channel (a) is 0.2. It is unlikely that the branching ratio changes significantly with temperature.

D23. OH + HCN. This reaction is pressure dependent. The recommended value is the high pressure limit measured by Fritz et al.² using a laser photolysis-resonance fluorescence apparatus. Phillips⁴ studied this reaction using a discharge flow apparatus at low pressures and found the rate coefficient to have reached the high pressure limit at ~10 Torr at 298 K. Fritz et al.'s results contradict this finding. They agree with Phillip's measured value, within a factor of two, at 7 Torr, but they find *k* to increase further with pressure. Bunkan et al.¹ report the ¹²C/¹³C and ¹⁴N/¹⁵N kinetic isotope effects at *T* = 298 K and *P* = 1.00 atm to be 0.9733 ± 0.0012 and 0.9840 ± 0.0016, respectively (uncertainties are 1σ). The reaction mechanism has been investigated theoretically by Galano³ and Bunkan et al. They find that OH adds (over a barrier of ~16 kJ mol⁻¹) to the carbon atom in HCN. It is predicted theoretically that, under atmospheric conditions, HC(OH)N reacts with O₂ to generate nitroso formaldehyde (HC(O)NO) and recycle OH.^{1,3} The rate constant for the HC(OH)N + O₂ reaction at *T* = 298 K and *P* = 1.00 atm is evaluated theoretically to be 9 × 10⁻¹⁶ cm³ molecule⁻¹ s⁻¹.

D24. OH + C₂H₆. There are numerous studies of this reaction at 298 K (Greiner,¹¹ Horne and Norrish,¹⁴ Greiner,¹² Overend et al.,²¹ Howard and Evenson,¹⁵ Leu,¹⁸ Lee and Tang,¹⁷ Tully et al.,²⁹ Jeong et al.,¹⁶ Smith et al.,²⁵ Baulch et al.,² Schmidt et al.,²³ Edney et al.,⁹ Tully et al.,²⁸ Nielsen et al.,²⁰ Stachnik et al.,²⁶ Wallington et al.,³⁰ Bourmada et al.,³ Zabarnick et al.,³¹ Abbatt et al.,¹ Schiffman et al.,²² Dobe et al.,⁷ Sharkey and Smith,²⁴ Finlayson-Pitts,¹⁰ Talukdar et al.,²⁷ Crowley et al.,⁶ Cavalli et al.,⁴ Donahue et al.,⁸ Clarke et al.,⁵ Heathfield et al.,¹³ and Li et al.¹⁹). The recommended value for *k*(298 K) is an average of the majority of the results reported at room temperature (Overend et al.,²¹ Howard and Evenson,¹⁵ Leu,¹⁸ Lee and Tang,¹⁷ Tully et al.,²⁹ Smith et al.,²⁵ Baulch et al.,² Schmidt et al.,²³ Tully et al.,²⁸ Stachnik et al.,²⁶ Wallington et al.,³⁰ Bourmada et al.,³ Zabarnick et al.,³¹ Abbatt et al.,¹ Schiffman et al.,²² Dobe et al.,⁷ Finlayson-Pitts,¹⁰ Talukdar et al.,²⁷ Crowley et al.,⁶ Cavalli et al.,⁴ Donahue et al.,⁸ Clarke et al.,⁵ Heathfield et al.,¹³ and Li et al.¹⁹). The room temperature studies not used were either of lower precision (as evidenced by data scatter) or yielded somewhat higher rate constants.

The temperature dependence of the rate coefficient below 298 K has been measured by Jeong et al.,¹⁶ Stachnik et al.,²⁶ Smith et al.,²⁵ Wallington et al.,³⁰ Talukdar et al.,²⁷ Crowley et al.,⁶ and Clarke et al.⁵ The last six of these studies are in good agreement (the data from Jeong et al.¹⁶ exhibiting noticeable upward curvature below 298 K). Thus the recommended value for E/R is derived from a combined fit to the data below 300 K from the aforementioned six studies after each data set was normalized to the recommended value for *k*(298 K).

D25. OH + CH₃CHO. The recommended values for $k(298\text{ K})$ and E/R come from a combined fit to the data of Sivakumaran and Crowley¹³ and Zhu et al.²¹ at $T \leq 300\text{ K}$. There are 14 other studies of this reaction that provide the room temperature rate constant (Morris et al.,⁹ Niki et al.,¹⁰ Atkinson and Pitts,¹ Kerr and Sheppard,⁷ Semmes et al.,¹² Michael et al.,⁸ Dobe et al.,⁶ Balestra-Garcia et al.,² Scollard et al.,¹¹ Tyndall et al.,¹⁷ Taylor et al.,¹⁴ D'Anna et al.,⁵ Wang et al.,²⁰ and Taylor et al.¹⁵). The average value of $k(298\text{ K})$ from all of these studies is identical to that derived from the above fit. The study by Michael et al.⁸ also provided data down to 244 K. While these data are far more scattered than those from Sivakumaran and Crowley¹³ and Zhu et al.,²¹ they are encompassed by the 95% confidence limits of the recommendation.

Measurements of H₂O formation yields were conducted by Wang et al.,²⁰ Butkovskaya et al.,³ and Vandenberk and Peeters.¹⁸ These investigators reported values of ~100%, $(97.7 \pm 4.7)\%$, and $(89 \pm 6)\%$, respectively at about room temperature. Butkovskaya et al.³ report identical yields at both 298 K and 248 K. Tyndall et al.¹⁶ concluded that more than 90% of the reaction proceeds via H-atom abstraction based on no measurable detection of acetic acid formation. Cameron et al.⁴ detected CH₃ and CH₃CO radicals and H-atoms. The major reaction pathway was determined to be $\text{CH}_3\text{CHO} + \text{OH} \rightarrow \text{CH}_3\text{CO} + \text{H}_2\text{O}$ with a measured yield of $(93 \pm 18)\%$. Butkovskaya et al.³ detected CH₂CHO radicals to obtain a branching ratio for H-atom abstraction from the CH₃ group of $5.1^{+2.4}_{-1.7}\%$. Vöhringer-Martinez et al.¹⁹ studied the effect of water vapor on the reaction rate constant at temperatures between 300 K and 60 K. They found little-to no effect at 300 K and enhancements approaching a factor of 2 at temperatures below 100 K.

D26. OH + C₂H₅OH. There are numerous studies of the reaction rate constant at room temperature (Campbell et al.,¹ Overend and Paraskevopoulos,¹³ Ravishankara and Davis,¹⁶ Kerr and Stocker,⁷ Greenhill and O'Grady,⁴ Wallington and Kurylo,¹⁸ Hess and Tully,⁵ Nelson et al.,¹⁰ Picquet et al.,¹⁴ Oh and Andino,¹¹ Sorensen et al.,¹⁷ Jimenez et al.,⁶ Wu et al.,¹⁹ Dillon et al.,³ Kovacs et al.,⁸ Rajakumar et al.,¹⁵ Carr et al.,² and Orkin et al.¹²). The recommended k(298 K) is an average of the rate constants measured by Campbell et al.,¹ Kerr and Stocker,⁷ Wallington and Kurylo,¹⁸ Hess and Tully,⁵ Nelson et al.,¹⁰ Sorensen et al.,¹⁷ Jimenez et al.,⁶ Wu et al.,¹⁹ Dillon et al.,³ Kovacs et al.,⁸ Rajakumar et al.,¹⁵ and Orkin et al.¹² The room temperature studies not used were either of lower precision (as evidenced by data scatter) or yielded systematically higher or lower rate constants. Comprehensive studies of this reaction at sub-ambient temperatures were done by Jimenez et al.,⁶ Dillon et al.,³ and Orkin et al.¹² The last two studies resulted in indistinguishable rate constants at low temperatures and coincide with the recommended value of k(298 K). The analysis of the data at low temperatures suggests a temperature independent reaction rate constant between 210 K and 298 K. This reaction has three possible product channels: (a) CH₃CH₂O + H₂O, (b) CH₃CHOH + H₂O, and (c) CH₂CH₂OH + H₂O. At room temperature, channel (b) is the major pathway accounting for (75% ± 15%) of the reaction (Meier et al.⁹) which is consistent with the thermochemistry of these three possible pathways. The branching ratio for channel (b) is expected to increase with decreasing temperature.

D27. OH + CH₃C(O)OH. The recommended values of $k(298\text{ K})$ and E/R are derived from a combined fit to the data of Singleton et al.,⁸ Butkovskaya et al.,¹ Crunaire et al.,² Vimal and Stevens,⁹ Khamaganov et al.,⁷ Huang et al.,⁶ and Huang et al.⁵ at $T \leq 300\text{ K}$. Data from these studies are in reasonable agreement below 300 K. However, above 300 K there is not a consistent picture of the temperature dependence of the rate constant with E/R values ranging from $\sim -500\text{ K}$ to $\sim -1000\text{ K}$. In an earlier study by Dagaut et al.³ at room temperature and above, an E/R value of $+170\text{ K}$ was obtained. For this reason data from this study were not included in the combined fit, although $k(298\text{ K})$ from this study is in good agreement with recommended value. All studies required corrections for the presence of acetic acid dimer especially at temperatures below 298 K and they assumed no reactivity between OH and the dimer. This latter assumption is based on results from Singleton et al.⁸ However, in the same study Singleton et al.⁸ found that the rate constant for the reaction of OH with the dimer of propionic acid is equal to or greater than that of the rate constant of OH with propionic acid monomer. This result suggests that uncertainties regarding the reactivity of acetic acid dimer may remain. Such uncertainties would propagate into uncertainties in the reactivity of the monomer, especially at lower temperatures.

Three studies give similar results for the reaction mechanism. Butkovskaya et al.¹ reported a yield of $(64 \pm 17)\%$ over the temperature range of 300–249 K for H-atom abstraction from the carboxyl group, ($\text{OH} + \text{CH}_3\text{C}(\text{O})\text{OH} \rightarrow \text{CH}_3 + \text{CO}_2 + \text{H}_2\text{O}$). At room temperature, De Smedt et al.⁴ and Crunaire et al.² reported similar yields of $(64 \pm 14)\%$ and $(78 \pm 13)\%$, respectively. Observations by Singleton et al.⁸ regarding the decrease in reactivity upon D substitution on the carboxylic site and no change in reactivity upon substitution on the methyl group, are reasonably consistent with these mechanistic studies.

D28. OH + C₃H₈. There are many measurements of the rate coefficients at 298 K. In this evaluation we have considered only the direct measurements (Greiner,¹⁰ Tully et al.,¹⁷ Droege and Tully,⁸ Schmidt et al.,¹⁴ Baulch et al.,² Bradley et al.,³ Abbatt et al.,¹ Schiffman et al.,¹³ Talukdar et al.,¹⁵ Mellouki et al.,¹² Donahue et al.,⁶ Clarke et al.,⁴ and Kozlov et al.¹¹). The 298 K value is the average of these thirteen studies. Greiner, Tully et al.,¹⁶ Droege and Tully, Talukdar et al., Mellouki et al., Donahue et al., Clarke et al. and Kozlov et al.¹¹ have measured the temperature dependence of this reaction. Donahue and Clark⁷ have shown that there is outstanding agreement between all of the data sets after correcting some of them for small offsets due to systematic calibration errors. Due to the significant curvature in the Arrhenius behavior over the studied temperature range, the recommended Arrhenius expression is only valid between 190 and 300 K. The recommended E/R is obtained from a composite fit to the four data sets (Kozlov et al., Clarke et al., Talukdar et al. and Mellouki et al.) at temperature below 300 K. Each data set was normalized to the recommended k(298 K). This reaction has two possible channels, i.e., abstraction of the primary and the secondary H-atom. Observations of both channels by Tully et al. and Droege and Tully indicate that the reaction exhibits non-Arrhenius behavior over a wide temperature range. The branching ratios were estimated from the latter study:

$$k_{\text{primary}} = 6.3 \times 10^{-12} \exp(-1050/T) \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$$

$$k_{\text{secondary}} = 6.3 \times 10^{-12} \exp(-580/T) \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$$

These numbers are in reasonable agreement with the older data of Greiner. The ratio of the rate coefficients for OH reactions with C₂H₆ and C₃H₈ has been measured by Finlayson-Pitts et al.⁹ and DeMore and Bayes.⁵ Our recommendations are in reasonable agreement with their ratios.

D29. OH + C₂H₅CHO. The recommended value at 298 K is an average of the results from Niki et al.,⁴ Audley et al.,¹ Kerr and Sheppard,³ Semmes et al.,⁶ Papagni,⁵ Thevenet,⁷ and D'Anna.² The temperature dependence has been measured by Thevenet. The E/R is taken from Thevenet and the A-factor is adjusted to reproduce k(298 K). Vandenberg and Peeters⁸ measured unity yields of H₂O from the reaction and conclude that the reaction proceeds exclusively by H-abstraction of the aldehydic H-atom.

D30. OH + 1-C₃H₇OH. There have been a number of room temperature measurements that are in excellent agreement. The recommended value is an average of the results from absolute kinetics studies by Overend and Paraskevopoulos,⁶ Wallington and Kurylo,⁷ Nelson et al.,⁴ and Yujing and Mellouki.⁹ Relative rate studies of Nelson et al., Oh and Andino,⁵ Wu et al.,⁸ and Cheema et al.³ are in excellent agreement with the

recommended value. The indirect study of Campbell² is consistent with, but 30% lower than the recommended value. The reaction is observed to be nearly temperature independent; Yujing and Mellouki find a slight positive temperature dependence while Cheema et al. find a small negative temperature dependence. The recommended E/R value is based on the direct study of Yujing and Mellouki. End product studies carried out by Azad and Andino¹ support predictions based on the structure-activity relationship that identify the primary reaction channels as hydrogen abstraction by the OH radical from the α (~75%) and β (~20%) carbons.

D31. OH + 2-C₃H₇OH. The recommended value at 298 K is an average of the absolute measurements by Overend and Paraskevopoulos,⁴ Wallington and Kurylo,⁵ Nelson et al.,³ Dunlop and Tully,¹ and Yujing and Mellouki.⁶ A relative rate study by Lloyd et al.² is, within its wide error limits, consistent with the recommendation. The temperature dependence is observed to vary little with temperature below 400 K. Measurements over the range 293-745 K by Dunlop and Tully revealed a “bowl” shaped temperature dependence, with a minimum in the rate coefficient observed at 378 K. The recommended E/R is based on the measurements of Yujing and Mellouki and, on account of the complex reaction behavior, is valid only for temperatures below 400 K. Temperature dependent data of Dunlop and Tully and Wallington and Kurylo are, within the experimental uncertainties, consistent with the recommendation. By using isotopic substitution, Dunlop and Tully determined that the primary reaction channel below 400 K involves H atom abstraction by OH from the α -site. This result is in agreement with estimates based on the structure-activity relationship (Yujing and Mellouki⁶).

D32. OH + C₂H₅C(O)OH. Studies of this reaction have been confined to 298 K and above on account of the tendency of propionic acid to dimerize at lower temperatures and higher concentrations. Kinetic isotope effects measured by Singleton et al.² are consistent with a two channel mechanism proposed previously for OH reaction with acetic acid. In the propionic acid case, the channel involving direct abstraction of an alkyl hydrogen is predominant, thus accounting for the observed temperature independence of the rate constant. The recommended temperature independent rate constant, is based on an average of the results of Singleton et al. and Dagout et al.¹ taken at a variety of temperatures between 298 K and 446 K. An study room temperature measurement by Zetsch and Stuhl³ is ~30% higher, but consistent with the recommendation. Further studies below 298 K would be desirable in order to investigate possible non-Arrhenius behavior. (Table: 06-2, Note: 06-2, Evaluated 06-2) [Back to Table](#)

D33. OH + CH₃C(O)CH₃. The rate coefficient for this reaction has been measured at temperatures close to 298 K by Cox et al.,² Zetsch,¹⁴ Chiorboli et al.,¹ Kerr and Stocker,⁵ Wallington and Kurylo,¹¹ LeCalve et al.,⁶ Wollenhaupt et al.,¹² Gierczak et al.,³ and Yamada et al.¹³ Cox reported only an upper limit of $<5 \times 10^{-13}$ cm³ molecule⁻¹ s⁻¹, which is consistent with this recommendation. The primary aim of Chiorboli et al. was to examine the atmospheric degradation of styrene, which produces acetone. They employed a relative rate measurement and reported a value of k(298 K) that is almost three times faster than the recommended value. Because of possible complications in their system, we have not included their results in arriving at the recommended value. Wallington and Kurylo, LeCalve et al., Wollenhaupt et al., Gierczak et al., and Yamada et al. have reported k as a function of temperature; all these studies directly measured the rate constant using the pulsed photolysis method where the temporal profile of OH was measured using resonance fluorescence or laser induced fluorescence. The extensive data of Wollenhaupt et al. and Gierczak et al. seem to show that this rate coefficient does not follow an Arrhenius expression. The results of LeCalve et al. and Wallington et al. are in general agreement with the results of Wollenhaupt et al. and Gierczak et al. The non-Arrhenius behavior was not evident in the results of Wallington et al. and LeCalve et al. because they measured the rate constant at a few temperatures and did not explore temperature below 240 K, where the curvature becomes increasingly evident. Yamada et al. measured k only above room temperature and their values are consistently lower than those of all the others noted above. As they noted in their paper, Yamada et al. did not measure the acetone concentration in the reactor and, thus, could have overestimated its concentration leading to consistently lower values of k. We have not included data of Yamada et al.¹³ in deriving the fit because of this possible systematic error and because they did not report k under atmospheric temperatures. The following recommendation reproduces all reported data, except that of Chiorboli et al. within the recommended uncertainty of 25% at all temperatures:

$$k(T) = 1.33 \times 10^{-13} + 3.82 \times 10^{-11} \exp(-2000/T) \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$$

This reaction can proceed via the abstraction of an H atom or via the formation of a complex that decomposes to give many different products, which include CH₃ + CH₃C(O)OH, CH₃OH + CH₃C(O), CH₄ + CH₃CO₂, and H₂O + CH₃C(O)CH₂. The branching ratios for the formation of different sets of products could vary with temperature. Wollenhaupt et al.¹² have deduced that CH₃ radicals are produced with a yield of ~50% at 298 K and ~30% at 233 K. A similar branching ratio has also been reported by Vasvari et al.¹⁰ The results of Gierczak et al. on the OH + CD₃C(O)CD₃ reaction, whose rate coefficient nearly obeys an Arrhenius expression between 240 and 400 K and is nearly an order of magnitude smaller than the non-deuterated analog at 250 K, suggest that H abstraction may be the dominant channel. Vandenberk et al.,⁹ Tyndall et al.,⁸ and Talukdar et al.,⁷ clearly show that CH₃C(O)OH is a minor, if not negligible, product of this reaction and that the reaction proceeds to abstract an H atom. The results of Yamada et al. are consistent with this finding. Theoretical calculations of Henon et al.⁴ and Vandenberk et al.⁹ also suggest that formation of acetic acid is negligible. We recommend that the products of this reaction be taken as H₂O and CH₃C(O)CH₂.

D34. OH + CH₂=C(CH₃)CHO (methacrolein). The recommended E/R is that obtained from an unweighted fit to $\ln k = \ln A - E/RT$ of the rate constants reported by Gierczak et al.⁷ (234-373 K), which is the only study that reports rate constants at $T < 295$ K. The recommended value for $k(298 \text{ K})$ is the average of ambient temperature rate constants obtained in the flash photolysis studies of Kleindienst et al.,⁹ Gierczak et al.,⁷ and Chuong and Stevens,² the turbulent flow reactor study of Chuong and Stevens,³ and the relative rate study of Atkinson et al.,¹ with all rate constants adjusted to 298 K using the recommended E/R. In a second relative rate study, Edney et al.⁶ obtain a value for $k(298 \text{ K})$ that is significantly faster than the rate constants reported in all other studies. Temperature-dependent rate constants reported by Kleindienst et al. and Chuong and Stevens in their flash photolysis studies are encompassed by the recommended error limits for all temperatures below 400 K. Product studies by Tuazon and Atkinson¹¹ and Orlando and Tyndall¹⁰ demonstrate that, in air at $T \sim 298 \text{ K}$ and $P \sim 1 \text{ atm}$, abstraction of the aldehydic hydrogen accounts for 45-50% of overall reactivity and addition to the double bond accounts for the rest; more than 80% of addition is to the terminal carbon. Chuong and Stevens³ observe OH recycling in the presence of O₂ and NO at $T = 300 \text{ K}$ and conclude that (i) methacrolein-based peroxy radicals (OH-methacrolein-OO) react with NO with $k \sim 2 \times 10^{-11} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ and (ii) the peroxy radical + NO reactions produce NO₂ with a yield of $\sim 90\%$ and organic nitrates with a yield of $\sim 10\%$. A turbulent flow reactor study by Hsin and Elrod⁸ obtains OH-methacrolein-OO + NO rate constants that are a factor of two slower than those reported by Chuong and Stevens. In a combined experimental/theoretical study, Crounse et al.⁴ provide evidence that OH-methacrolein-OO undergoes a 1,4 H shift of the aldehydic hydrogen to OO at a rate of $\sim 0.5 \text{ s}^{-1}$ to form a radical that rapidly decomposes to recycle OH. In a theoretical study, da Silva concludes that chemically

activated OH–methacrolein and OH–methacrolein–OO strongly impact product distributions and OH recycling.⁵

D35. OH + CH₃C(O)CH=CH₂ (MVK). The recommendation is based on the temperature-dependent flash photolysis studies of Kleindienst et al.⁷ and Gierczak et al.,⁴ the room temperature turbulent flow reactor study of Chuong and Stevens,³ and the room temperature relative rate studies of Atkinson et al.¹ and Holloway et al.⁵ Chuong and Stevens² observe pressure-dependent rate constants in 1–5 Torr Helium over the temperature range 300–422 K. All data used to arrive at the recommendation were obtained under (presumably) high pressure limit conditions, i.e., $P > 16$ Torr. All data points reported in each temperature dependent study were scaled by a factor equal to the ratio $k(298)_{\text{Arr}}/k(298)_{\text{ave}}$ where $k(298)_{\text{Arr}}$ is the 298 K rate constant obtained from the best fit Arrhenius expression describing the individual T-dependent data set and $k(298)_{\text{ave}}$ is the average of all reported high-P limit room temperature rate constants. The best fit Arrhenius expression for the scaled data is recommended. A product study by Tuazon and Atkinson⁸ demonstrates that reactivity is dominated by addition to the double bond with 72 ± 28 % of the addition being to the terminal carbon. Chuong and Stevens³ observe OH recycling in the presence of O₂ and NO at $T = 300$ K and conclude that (i) MVK-based peroxy radicals (OH-MVK-OO) react with NO with $k \sim 2 \times 10^{-11} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ and (ii) the peroxy radical + NO reactions produce NO₂ with a yield of ~90% and organic nitrates with a yield of ~10%. A turbulent flow reactor study by Hsin and Elrod⁶ obtains OH-MVK-OO + NO rate constants that are more than a factor of two slower than those reported by Chuong and Stevens.

D36. OH + CH₂=C(CH₃)CH=CH₂. The recommended E/R is the average of values obtained from the temperature-dependent data sets of Kleindienst et al.,¹² Campuzano-Jost et al.,^{2,3} Gill and Hites,⁷ Park et al.,¹⁶ and Hites and Turner;⁹ each data set was analyzed using an unweighted fit to $\ln k = \ln A - E/RT$. The recommended $k(298\text{ K})$ is the average of the values obtained from the best fit Arrhenius expressions for the five temperature-dependent studies plus the ambient temperature results reported by Winer et al.²⁰ (based on data reported by Grimsrud et al.⁸), Cox et al.,⁵ Ohta,¹⁵ Atkinson and Aschmann,¹ Edney et al.,⁶ Stevens et al.,¹⁹ McGivern et al.,¹³ Zhang et al.,²¹ McQuaid et al.,¹⁴ Iida et al.,¹⁰ Karl et al.,¹¹ Singh and Li.¹⁷ Ambient temperature results obtained at temperatures other than 298 K were adjusted using the recommended E/R. Only results obtained under (investigator-reported) high pressure limit conditions are considered; this excludes the data of Chuong and Stevens⁴ at $T > 300\text{ K}$ and the data of Singh and Li at $T = 340\text{ K}$. Data from the Laval nozzle study of Spangenberg et al.¹⁸ are not considered because the investigated T , P conditions are not relevant for application to atmospheric chemistry. Singh and Li report the Arrhenius expression $k = 2.33 \times 10^{-11} \exp(444/T) \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ 240–340 K; their reported temperature dependence is not used to evaluate E/R because (high pressure limit) rate constants are reported only at 298 K. Although the detailed pressure-dependence remains a subject of disagreement,^{4,10,11,13,19} it is clear that the reaction is in its high pressure limit under all relevant atmospheric conditions.

D37. OH + CH₃CN. This rate coefficient has been measured as a function of temperature by Harris et al.² between 298 and 424 K, Kurylo and Knable⁴ between 250 and 363 K, Rhasa⁶ between 295 and 520 K, and Hynes and Wine³ between 256 and 388 K. In addition, the 298 K value has been measured by Poulet et al.⁵ The 298 K results of Harris et al. are in disagreement with all other measurements and therefore have not been included. The recommended 298 K value is a weighted average of all other studies. The temperature dependence was computed using the results of Kurylo and Knable, the lower temperature values (i.e., 295–391 K) of Rhasa, and the data of Hynes and Wine. Three points are worth noting: (a) Rhasa observed a curved Arrhenius plot even in the temperature range of 295 to 520 K, and therefore extrapolation of the recommended expression could lead to large errors; (b) Hynes and Wine observed a pressure dependent increase of $k(298\text{ K})$ that levels off at about 1 atmosphere, and this observation is contradictory to the results of other investigations; (c) Hynes and Wine have carried out extensive pressure, temperature, O₂ concentration, and isotope variations in this reaction. Hynes and Wine postulate that the reaction proceeds via addition as well as abstraction pathways. They observe OH regeneration in the presence of O₂. The recommended $k(298\text{ K})$ and E/R are applicable for only lower tropospheric conditions. Because of the unresolved questions of pressure dependence, the recommended value may not be applicable under upper tropospheric and stratospheric conditions. At $T = 296\text{ K}$ and $P = 700\text{ Torr}$ air, Tyndall et al. observe that HC(O)CN, an expected end product when reaction is initiated by H-abstraction, is formed with a yield of 0.4 ± 0.2 .⁷ The OH regeneration in the presence of O₂ reported by Hynes and Wine has been explained theoretically by Galano as resulting from initial formation of a CH₃C(OH)N adduct that rearranges and dissociates to OH + CH₃C(O)NO.¹ In agreement with the observations of Hynes and Wine and Tyndall et al., Galano's theoretical analysis predicts similar branching ratios for H-abstraction and addition. D38. OH + CH_3ONO_2 . The rate coefficient for this reaction at 298 K has been measured by Kerr and Stocker,⁴ Nielsen et al.,⁵ Gaffney et al.,² Talukdar et al.,² Kakesu et al.,³ and Shallcross et al.⁶ The results of Kerr and Stocker and of Nielsen et al. are a factor of ten higher than those reported by the other groups. There are no obvious reasons for the reported differences but the lower values are preferred for a number of reasons. Firstly, Talukdar et al. have carried out a large number of checks which ruled out possible effects in their system due to the regeneration of OH via secondary reactions, to bath gas pressure, and to formation of an adduct that could undergo further reaction in the presence of oxygen. Secondly, the lower values are more consistent with reactivity predictions of Atkinson and Aschmann,¹ who assumed that the series of nitrate reactions proceed by H-atom abstraction pathways. Kinetic measurements of Talukdar et al. performed with isotopically substituted hydroxyl radical (OH, ^{18}OH , and OD) and methyl nitrate (CH_3ONO_2 and CD_3ONO_2) are consistent with this reaction proceeding via an H-atom abstraction pathway. Accordingly, the recommended value of $k(298\text{ K})$ is based on an average of the values given by Gaffney et al., Talukdar et al., Kakesu et al., and Shallcross et al. Further verification of the reaction mechanism by identification of the products of the reaction is needed. The temperature dependence of the rate coefficient has been measured by Nielsen et al., Talukdar et al., and Shallcross et al. While Nielsen et al. report a negative activation energy, Talukdar et al. and Shallcross et al. report positive values. For the reasons given above, the temperature dependence recommended here is based on an average of Talukdar et al. and Shallcross et al. (Table: 06-2, Note: 06-2, Evaluated 06-2) [Back to Table](#)

Rate constants for the reaction between OH and CH_3ONO_2 and $\text{C}_2\text{H}_5\text{ONO}_2$ over a range of pressure and temperature. *J. Chem. Soc. Faraday Trans.* **1997**, *93*, 2807-2811.

D39. OH + $\text{CH}_3\text{C(O)O}_2\text{NO}_2$ (PAN). This reaction has been studied by four groups Winer et al.,⁴ Wallington et al.,³ Tsalkani et al.,² and Talukdar et al.¹ Winer et al. obtained only an upper limit for the rate coefficient. Tsalkani et al. noted that their system was very ill-behaved and obtained a value of $k(298\text{ K})$ that is a factor of ~ 2 lower than that obtained by Wallington et al. The pulsed photolysis study of Wallington et al. yielded consistent results, but PAN was not directly measured and photodissociation of H_2O in the vacuum UV, where PAN absorbs strongly, was used as the OH source. The recent study of Talukdar et al.¹ yielded much lower rate coefficients. These investigators measured the PAN concentration directly in their system, minimized secondary reactions due to the photodissociation of PAN, and carried out extensive tests for

decomposition of PAN, impurities, and secondary reactions. The recommended upper limit is a factor of two higher than the highest value measured by Talukdar et al. at 298 K and at 272 K. The quoted upper limit is expected to be valid at all atmospheric temperatures. The products of the reaction are not known. Further measurements of the rate coefficients and information on the reaction pathways are needed.

D40. OH + C₂H₅ONO₂. The rate constant for this reaction at 298 K has been measured by Kerr and Stocker,² Nielsen et al.,³ Talukdar et al.,⁵ Kakesu et al.,¹ and Shallcross et al.⁴ As in the case of the reaction of OH with CH₃ONO₂, the results of Kerr and Stocker and of Nielsen et al. are larger (by a factor of 3) than those of the more recent studies. The reasons for the differences are not clear. Because of the exhaustive tests carried out (see the note for the OH + CH₃ONO₂ reaction), the values of Talukdar et al., Kakesu et al., and Shallcross et al. are recommended. Nielsen et al., Talukdar et al., and Shallcross et al. have measured the rate constant as a function of temperature. As with the OH + CH₃ONO₂ reaction, Nielsen et al. report a negative activation energy while Talukdar et al. and Shallcross et al. have observed a small positive activation energy. Talukdar et al. note that the rate coefficient for this reaction does not strictly follow Arrhenius behavior, consistent with the abstraction of both the primary and the secondary H atoms. Above 298 K, E/R values measured by Shallcross et al. and Talukdar et al. are in excellent agreement. Only Talukdar et al. have kinetics data below 298 K and the recommended E/R value was obtained by fitting the rate coefficients measured by Talukdar et al. at or below 298 K. The large uncertainty encompasses the results of Kerr and Stocker and Nielsen et al. (Table: 06-2, Note: 06-2, Evaluated 06-2) [Back to Table](#)

D41. OH + 1-C₃H₇ONO₂. The reaction has been studied by Kerr and Stocker² and Atkinson and Aschmann¹ at room temperature and by Nielsen et al.³ between 298 and 368 K. The results of the three studies are in good agreement at room temperature. Nielsen et al. find that the reaction is temperature independent within the measurement uncertainty over the range studied. However as discussed above, the Nielsen et al. results for the analogous reactions of OH with CH₃ONO₂ and C₂H₅ONO₂, yield negative activation energies that disagree with the positive activation energies obtained by others. Judging from the E/R's for the analogous reactions, one might expect the E/R for this reaction to be on the order of 300 K. Accordingly, we place a large uncertainty on the recommended temperature dependence. A thorough investigation of the temperature dependence of this reaction is needed.

D42. OH + 2-C₃H₇ONO₂. The reaction has been studied by Atkinson and Aschmann,¹ Atkinson et al.,² and Becker and Wirtz³ at room temperature and by Talukdar et al.⁴ over the range 233 and 395 K. The results of Atkinson and Aschmann supersede those of Atkinson et al. There is fair agreement between the results of the three studies at room temperature, with roughly a factor of two spread in the values. The recommendation is based on an average of the room temperature values and the E/R measured by Talukdar et al.

D43. HO₂ + CH₂O. There is sufficient evidence to suggest that HO₂ adds to CH₂O (Su et al.,^{2,3} Veyret et al.,⁵ Zabel et al.,⁶ Barnes et al.,¹ and Veyret et al.⁴). The recommended *k*(298 K) is the average of values obtained by Su et al.,² Veyret et al.,⁵ and Veyret et al.⁴ The temperature dependence observed by Veyret et al.⁴ is recommended. The value reported by Barnes et al. at 273 K is consistent with this recommendation. The adduct HO₂•CH₂O seems to isomerize to HOCH₂OO reasonably rapidly and reversibly. There significant discrepancies between measured values of the equilibrium constants for this reaction.

D44. HO₂ + CH₃O₂. This recommendation is taken from the evaluated review of Tyndall et al.⁴ The kinetics of this reaction have been studied by using UV absorption following pulsed photolytic production of the radicals. These authors first analyzed the available data for the products of the reaction and concluded that the major products are CH₃OOH and O₂. They used this product yield information with their evaluated UV absorption cross sections for HO₂ and CH₃O₂ to reanalyze the UV absorption profiles measured in kinetics experiments by Dagaut et al.¹ and by Lightfoot et al.,³ the two groups that carried out the most extensive studies. They found that rate coefficients reported by these two groups need to be increased by ~20%. The recommended value is based on the average of the corrected data from these two groups. The temperature dependence was evaluated by Tyndall et al. by assuming that the absorption cross sections of CH₃O₂ and HO₂ are independent of temperature at the wavelengths used for the kinetics studies. The products of this reaction are shown as CH₃OOH + O₂ in the table. However, Elrod et al.² have determined that the reaction also yields

CH₂O + H₂O + O₂ with yields that range from 0.1 at 298 K to 0.3 at 220 K. In anticipation of further work, the recommended product yield for the CH₂O channel is zero.

D45. HO₂ + C₂H₅O₂. The recommended value is the weighted average of those measured by Cattell et al.,¹ Dagaut et al.,² Fenter et al.,³ and Maricq and Szenté.⁴ In all experiments the rate coefficient was obtained by modeling the reaction system. Also, the calculated rate coefficients depended on the UV absorption cross sections of both C₂H₅O₂ and HO₂. The absorption cross section of C₂H₅O₂ is not well-defined. The value reported by Dagaut et al. would be ~30% higher if the cross sections used by Maricq and Szenté were used. The recommended E/R is derived from the measurements of Dagaut et al., Fenter et al., and Maricq and Szenté. Wallington and Japar⁵ have shown that C₂H₅O₂H and O₂ are the only products of this reaction. (Table: 94-26, Note: 94-26, Evaluated 94-26) [Back to Table](#)

D46. HO₂ + CH₃C(O)O₂. This recommendation is taken from the evaluated review of Tyndall et al.⁵ This reaction has two sets of products:

The majority of the reaction proceeds via channel (a), but there is clear evidence for channel (b). Tyndall et al. reevaluated the available data on end products of this reaction, particularly those of Crawford et al.,¹ Moortgat et al.,³ and Horie and Moortgat,² and concluded that channel (a) contributes ~80% while channel (b) contributes ~20% at 298 K. They also concluded that $k_a/k_b = 37 \times \exp(-660/T)$ with a large uncertainty in this value. They derived the overall rate coefficient for this reaction, which has been measured only by following the radical concentrations via UV absorption. They based their recommendation mostly on the results of Moortgat et al.³ and Tomas et al.⁴

D47. $\text{HO}_2 + \text{CH}_3\text{C}(\text{O})\text{CH}_2\text{O}_2$. This recommendation is from Tyndall et al.² This reaction has been studied by only Bridier et al.¹ and Tyndall et al. based their recommendation on this one study.
(Table: 02-25, Note: 02-25, Evaluated 02-25) [Back to Table](#)

- (1) Bridier, I.; Veyret, B.; Lesclaux, R.; Jenkin, M. E. Flash photolysis study of the UV spectrum and kinetics of reactions of the acetylperoxy radical. *J. Chem. Soc. Faraday Trans.* **1993**, *89*, 2993-2997.

D48. $\text{NO}_3 + \text{CH}_2=\text{C}(\text{CH}_3)\text{CHO}$ (methacrolein). The recommendation is the average of the results of relative rate studies by Chew et al.² and Canosa-Mas et al.¹ The Chew et al. study supersedes an earlier study by the same group.³ Chew et al. report two rate constants obtained using propene and 1-butene as reference compounds while Canosa-Mas et al. report a single rate constant obtained using propene as the reference. Two flow tube studies^{1,4} report faster rate constants, presumably due to the presence of reactive impurities in methacrolein samples. Reaction can proceed via addition to the double bond or via abstraction of the aldehydic hydrogen atom. In 760 Torr O_2 , Canosa-Mas et al. observe production of both methyl glyoxal ($\text{CH}_3\text{C}(\text{O})\text{CHO}$), likely formed via reactions involving a primary addition product, and MPAN ($\text{CH}_2=\text{C}(\text{CH}_3)\text{C}(\text{O})\text{OONO}_2$), likely formed via reactions involving the H-abstraction product. Product yields have not been reported.

- (3) Kwok, E. S. C.; Aschmann, S. M.; Arey, J.; Atkinson, R. Product formation from the reaction of the NO_3 radical with isoprene and rate constants for the reactions of methacrolein and methyl vinyl ketone with the NO_3 radical. *Int. J. Chem. Kinet.* **1996**, *28*, 925-934.
- (4) Rudich, Y.; Talukdar, R. K.; Fox, R. W.; Ravishankara, A. R. Rate coefficients for reactions of NO_3 with a few olefins and oxygenated olefins. *J. Phys. Chem.* **1996**, *100*, 5374-5381, doi:10.1021/jp953079g.

D49. $\text{NO}_3 + \text{CH}_3\text{C}(\text{O})\text{CH}=\text{CH}_2$ (MVK). In a low pressure flow tube study where NO_3 was produced by thermal decomposition of N_2O_5 and detected by long path diode laser absorption at 662 nm, Rudich et al.³ measured a rate constant of $(1.0 \pm 0.2) \times 10^{-16} \text{ cm}^3\text{molecule}^{-1} \text{ s}^{-1}$; acknowledging that "our experiment is not suited to accurately measuring such low rate coefficients," Rudich et al. chose to report their result as an upper limit, i.e., $k < 1.2 \times 10^{-16} \text{ cm}^3\text{molecule}^{-1} \text{ s}^{-1}$. In units of $10^{-16} \text{ cm}^3\text{molecule}^{-1} \text{ s}^{-1}$, Canosa-Mas et al.¹ report $k = 3.2 \pm 0.6$ based on a low pressure flow tube study where NO_3 was produced via the $\text{F} + \text{HNO}_3$ reaction and detected by laser induced fluorescence; these authors also obtained a rate constant of 5.3 ± 1.9 (corrected using updated information for the $\text{NO}_3 + \text{C}_2\text{H}_4$ reference reaction) from a relative rate study in 760 Torr N_2 . Kwok et al. report $k < 6 \times 10^{-16} \text{ cm}^3\text{molecule}^{-1} \text{ s}^{-1}$ based on a relative rate study in 740 Torr air using $\text{NO}_3 + \text{C}_3\text{H}_6$ as the reference reaction.² The recommendation, $k < 4 \times 10^{-16} \text{ cm}^3\text{molecule}^{-1} \text{ s}^{-1}$, is consistent with the results reported in both absolute rate constant determinations. The initial step in the reaction of NO_3 with MVK is addition of NO_3 to the double bond. In 760 Torr O_2 bath gas, Canosa-Mas et al. observe methyl glyoxal ($\text{CH}_3\text{C}(\text{O})\text{CHO}$) as a reaction product; they propose a pathway where NO_3 adds to the terminal carbon followed by formation of a peroxy radical that reacts with a second NO_3 to form (via multiple steps) $\text{CH}_3\text{C}(\text{O})\text{CHO} + \text{HCHO} + 2\text{NO}_2 + \text{O}_2$.

D50. $\text{NO}_3 + \text{CH}_2=\text{C}(\text{CH}_3)\text{CH}=\text{CH}_2$. The recommended E/R is obtained from an unweighted fit of the single temperature-dependent data set of Dlugokencky and Howard⁶ to $\ln k = \ln A - E/RT$ ($E/R = 446 \text{ K}$, 251-381 K). The recommended 298 K rate constant is an unweighted average of ambient temperature results reported by Atkinson et al.,^{1,2} Dlugokencky and Howard⁶ (rate constant obtained from the best fit Arrhenius expression), Barnes et al.,³ Wille et al.,¹⁰ Ellermann et al.,⁷ Berndt and Bøge,⁵ Suh et al.,⁹ and Stabel et al.⁸ Ambient temperature results obtained at temperatures other than 298 K were adjusted using the recommended E/R. The 298 K rate constant reported by Benter and Schindler⁴ is not considered because (a) it is faster than all others in the literature and (b) it is superseded by a later study from the same group.¹⁰

D51. $\text{NO}_3 + \text{CO}$. The upper limit is based on the results of Hjorth et al.,² who monitored isotopically labeled CO loss in the presence of NO_3 by FTIR. Burrows et al.¹ obtained an upper limit of $4 \times 10^{-16} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$, which is consistent with the Hjorth et al. study. Products are expected to be $\text{NO}_2 + \text{CO}_2$, if the reaction occurs.

D52. $\text{NO}_3 + \text{CH}_2\text{O}$. There are three measurements of this rate coefficient at 298 K: Atkinson et al.,¹ Cantrell et al.,² and Hjorth et al.³ The value reported by Atkinson et al.,¹ $k = (3.23 \pm 0.26) \times 10^{-16} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$, is corrected to $5.8 \times 10^{-16} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ to account for the different value of the equilibrium constant for the $\text{NO}_3 + \text{NO}_2 \leftrightarrow \text{N}_2\text{O}_5$ reaction that was measured subsequent to this study by the same group using the same apparatus. This correction is in accordance with their suggestion (Tuazon et al.⁴). The values reported by Cantrell et al. and Hjorth et al., $k = 6.3 \times 10^{-16} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ and $(5.4 \pm 1.1) \times 10^{-16} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$, respectively, are in good agreement with the corrected value of Atkinson et al. The recommended value is the average of these three studies. Cantrell et al. have good evidence to suggest that HNO_3 and CHO are the products of this reaction. The temperature dependence of this rate coefficient is unknown, but comparison with the analogous $\text{NO}_3 + \text{CH}_3\text{CHO}$ reaction suggests a large E/R.

Chem.* **1984**, *88*, 3095-3098, doi:10.1021/j150658a033.

D53. $\text{NO}_3 + \text{CH}_3\text{CHO}$. There are four measurements of this rate constant: Morris and Niki,⁴ Atkinson et al.,¹ Cantrell et al.,² and Dlugokencky and Howard.³ The value reported by Atkinson et al., $k = (1.34 \pm 0.28) \times 10^{-15} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$, is corrected to $2.4 \times 10^{-15} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ as discussed for the $\text{NO}_3 + \text{H}_2\text{CO}$ reaction above and as suggested by Tuazon et al.⁵ The recommended value is the average of the values obtained by Atkinson et al., Cantrell et al., and Dlugokencky and Howard. The results of Morris and Niki agree with the recommended value when their original data are re-analyzed using a more recent value for the equilibrium constant for the reaction $\text{NO}_2 + \text{NO}_3 \leftrightarrow \text{N}_2\text{O}_5$ as shown by Dlugokencky and Howard. Dlugokencky and Howard have studied the temperature dependence of this reaction. Their measured value of E/R is recommended. The A-factor has been calculated to agree with the $k(298 \text{ K})$ recommended here. Morris and Niki, and Cantrell et al. observed the formation of HNO_3 and PAN in their studies, which strongly suggests that HNO_3 and CH_3CO are the products of this reaction.

N., Jr. Direct determination of the equilibrium constant at 298 K for the $\text{NO}_2 + \text{NO}_3 \leftrightarrow \text{N}_2\text{O}_5$ reactions. *J. Phys. Chem.* **1984**, *88*, 3095-3098, doi:10.1021/j150658a033.

D54. $\text{CH}_3 + \text{O}_2$. This bimolecular reaction is not expected to be important, based on the results of Baldwin and Golden,¹ who found $k < 5 \times 10^{-17} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ for temperatures up to 1200 K. Klais et al.³ failed to detect OH (via $\text{CH}_3 + \text{O}_2 \rightarrow \text{CH}_2\text{O} + \text{OH}$) at 368 K and placed an upper limit of $3 \times 10^{-16} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ for this rate coefficient. Bhaskaran et al.² measured $k = 1 \times 10^{-11} \exp(-12,900/T) \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ for $1800 < T < 2200$ K. The latter two studies thus support the results of Baldwin and Golden. Studies by Selzer and Bayes⁵ and Plumb and Ryan⁴ confirm the low value for this rate coefficient. Previous studies of Washida and Bayes⁶ are superseded by those of Selzer and Bayes. Plumb and Ryan have placed an upper limit of $3 \times 10^{-16} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ based on their inability to find HCHO in their experiments. A study by Zellner and Ewig⁷ suggests that this reaction is important at combustion temperature but is unimportant for the atmosphere.

D55. $\text{CH}_3 + \text{O}_3$. The recommended A-factor and E/R are those obtained from the results of Ogryzlo et al.⁴ The results of Simonaitis and Heicklen,⁶ based on an analysis of a complex system, are not used. Washida et al.⁷ used $\text{O} + \text{C}_2\text{H}_4$ as the source of CH_3 . Studies on the $\text{O} + \text{C}_2\text{H}_4$ reaction (Schmoltner et al.,⁵ Kleinermmanns and Luntz,³ Hunziker et al.,¹ and Inoue and Akimoto²) have shown this reaction to be a poor source of CH_3 . Therefore, the results of Washida et al. are also not used.

D56. $\text{HCO} + \text{O}_2$. The value of $k(298\text{ K})$ is the average of the determinations by Washida et al.,¹² Shibuya et al.,⁸ Veyret and Lesclaux,¹¹ Langford and Moore,³ Nesbitt et al.,⁵ Temps et al.,⁹ and Ninomiya et al.⁶ There are three measurements of k where HCO was monitored via the intracavity dye laser absorption technique (Reilly et al.,⁷ Nadtochenko et al.,⁴ and Gill et al.¹). Even though these studies agree with the recent measurements of Nesbitt et al., the only recent measurement to obtain a low value, they have not been included in deriving the recommended value of $k(298\text{ K})$. However, the uncertainty has been increased to overlap with those measurements. The main reason for not including them in the average is the possible depletion of O_2 in those static systems (as suggested by Veyret and Lesclaux). Also, these experiments were designed more for the study of photochemistry than kinetics. The temperature dependence of this rate coefficient has been measured by Veyret and Lesclaux, Timonen et al.,¹⁰ and Nesbitt et al. While Timonen et al. obtain a slightly positive activation energy, Veyret and Lesclaux, and Nesbitt et al. measure slightly negative activation energy. It is very likely that the Arrhenius expression is curved. We recommend an E/R value of zero, with an uncertainty of 100 K. Veyret and Lesclaux preferred a T^n form ($k = 5.5 \times 10^{-11} T^{-(0.4 \pm 0.3)} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$). Hsu et al.² suggest that this reaction proceeds via addition at low temperature and abstraction at higher temperatures.

D57. CH₂OH + O₂. The rate coefficient was first measured directly by Radford⁷ by detecting the HO₂ product in a laser magnetic resonance spectrometer. The wall loss of CH₂OH could have introduced a large error in this measurement. Radford also showed that the previous measurement of Avramenko and Kolesnikova¹ was in error. Wang et al.⁸ measured a value of 1.4×10^{-12} cm³ molecule⁻¹ s⁻¹ by detecting the HO₂ product. Recently, Dobe et al.,² Grotheer et al.,³ Payne et al.,⁶ Grotheer et al.,⁴ and Nesbitt et al.⁵ have measured k(298 K) to be close to 1.0×10^{-11} cm³ molecule⁻¹ s⁻¹ under conditions where wall losses are small. This reaction appears to exhibit a very complex temperature dependence. Based on the recent data of Grotheer et al.⁴ and Nesbitt et al.,⁵ k appears to increase from 200 K to approximately 250 K in an Arrhenius fashion, levels off at approximately 300 K, decreases from 300 to 500 K, and finally increases as temperature is increased. This complex temperature dependence is believed to be due to the formation of a CH₂(OH)•O₂ adduct which can isomerize to CH₂O•HO₂ or decompose to reactants. The CH₂O•HO₂ isomer can also decompose to CH₂O and HO₂ or reform the original adduct. At temperatures less than 250 K, the data of Nesbitt et al. suggests an E/R value of ~1700 K. For atmospheric purposes, the value E/R = 0 is appropriate.

D58. CH₃O + O₂. The recommended value for k(298 K) is the average of those reported by Lorenz et al.⁵ and Wantuck et al.⁸ The recommended E/R was obtained using the results of Gutman et al.⁴ (413 to 608 K), Lorenz et al.⁵ (298 to 450 K), and Wantuck et al.⁸ (298 to 498 K). These investigators have measured k directly under pseudo-first order conditions by following CH₃O via laser induced fluorescence. Wantuck et al. measured k up to 973 K and found the Arrhenius plot to be curved; only their lower temperature data are used in the fit to obtain E/R. The A factor has been adjusted to reproduce the recommended k(298 K). The previous high temperature measurements (Barker et al.¹ and Batt and Robinson²) are in reasonable agreement with the derived expression. This value is consistent with the 298 K results of Cox et al.,³ obtained from an end product analysis study, and with the upper limit measured by Sanders et al.⁷ The A-factor appears low for a hydrogen atom transfer reaction. The reaction may be more complicated than a simple abstraction. At 298 K, the products of this reaction are HO₂ and CH₂O, as shown by Niki et al.⁶

D59. CH₃O + NO. The reaction of CH₃O with NO proceeds mainly via addition to form CH₃ONO (Batt et al.,¹ Wiebe and Heicklen,⁴ Frost and Smith,² and Ohmori et al.³). However, a fraction of the energized CH₃ONO adducts decomposes to CH₂O + HNO, and appear to be a bimolecular channel. This reaction has been investigated by direct detection of CH₃O via laser-induced fluorescence (Zellner,⁵ Frost and Smith,² Ohmori et al.³). End-product studies (Batt et al.,¹ Wiebe and Heicklen⁴) are generally consistent with this conclusion. Since the fraction of the CH₃ONO adduct that falls apart to CH₂O + HNO decreases with increasing pressure and decreasing temperature, it is not possible to derive a "bimolecular" rate coefficient. A value of $k < 8 \times 10^{-12} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ can be deduced from the work of Frost and Smith² and Ohmori et al.³ for lower atmospheric conditions.

D60. CH₃O + NO₂. The reaction of CH₃O with NO₂ proceeds mainly via the formation of CH₃ONO₂. However, a fraction of the energized adducts fall apart to yield CH₂O + HNO₂. The bimolecular rate coefficient reported here is for the fraction of the reaction that yields CH₂O and HNO₂. It is not meant to represent a bimolecular metathesis reaction. The recommended value was derived from the study of McCaulley et al.¹ and is discussed in the section on association reactions.

D61. CH₂OO + H₂O. The recommendation is based on the results of Chao et al.,⁴ who coupled CH₂OO production by UV laser flash photolysis or CH₂I₂/O₂ with time-resolved UV spectroscopic monitoring of CH₂OO kinetics; they observed a well-defined quadratic dependence of the pseudo-first order CH₂OO decay rate constant on [H₂O], and obtained the recommended upper limit bimolecular rate constant from estimation of the maximum possible contribution to the observed kinetics from a process whose pseudo-first order rate constant varied linearly as a function of [H₂O]. A similar experiment is reported by Lewis et al.,⁵ but with more scatter in the data. A less sensitive upper limit is also reported by Welz et al.,¹¹ who observed no significant increase in the CH₂OO decay rate upon addition of up to $3 \times 10^{16} \text{ H}_2\text{O per cm}^3$ to their reaction mixtures; Welz et al. produced CH₂OO in the same manner as Chao et al. and Lewis et al., but employed photoionization mass spectrometry as the CH₂OO detection technique and lower total pressures than the other studies. Theoretical work by Ryzhkov and Ariya⁸ suggests that the CH₂OO + H₂O rate constant may be

significantly slower than any of the experimental upper limits. Experimental rate constants slower than the recommended upper limit are reported by Ouyang et al.⁶ and Stone et al.⁹ As discussed by Lewis et al., misinterpretation of complex chemical mechanisms are likely to have been a problem in the Ouyang et al. and Stone et al. studies; also, Chao et al. suggest that interferences to detected signals from reaction products could have been a problem in these studies. Suto et al.¹⁰ and Becker et al.³ report significantly faster rate constants than those obtained in other studies based on competitive kinetics results with $\text{CH}_2\text{OO} + \text{SO}_2$ used as the reference reaction. Both Suto et al. and Becker et al. employed the highly exothermic $\text{C}_2\text{H}_4 + \text{O}_3$ reaction to generate CH_2OO , suggesting that reactions of non-thermalized CH_2OO could impact the competitive kinetics results. Also, the $\text{O}_3 + \text{C}_2\text{H}_4$ reaction is known to produce OH. Since OH was not scavenged in the Suto et al. or Becker et al. studies, interfering side reactions could result from its presence. Based on theoretical studies by Aplincourt and Ruiz-López,² Ryzhkov and Ariya,⁷ and Anglada et al.,¹ it is well-established that CH_2OO interacts with H_2O to form a hydrogen bonded complex that isomerizes rapidly to hydroxymethyl hydroperoxide (HMHP, HOCH_2OOH). HMHP is stable $\sim 190 \text{ kJ mol}^{-1}$ relative to $\text{CH}_2\text{OO} + \text{H}_2\text{O}$.

D62. $\text{CH}_2\text{OO} + (\text{H}_2\text{O})_2$. The recommendation for $k(298 \text{ K})$ is the average of the value reported by Chao et al.³ and the value obtained from an Arrhenius expression describing the temperature dependent rate constants reported by Smith et al.¹⁰ The Smith et al. study reports the only available temperature dependent data, so the recommended E/R is obtained from the Arrhenius fit to their data. Both Chao et al. and Smith et al. (same research group) coupled CH_2OO production by UV laser flash photolysis of $\text{CH}_2\text{I}_2/\text{O}_2$ with time-resolved UV spectroscopic monitoring of CH_2OO kinetics; in both studies well-defined quadratic dependence of the pseudo-first order CH_2OO decay rate constant on $[\text{H}_2\text{O}]$, and the source of information they used to obtain an equilibrium constant for $2 \text{ H}_2\text{O} \leftrightarrow (\text{H}_2\text{O})_2$ is also the basis for the recommendation in Table 3 of this document.⁶ A similar (to Chao et al. and Smith et al.) experiment is reported by Lewis et al.,⁵ but with more

scatter in the data; these authors obtain a rate constant somewhat slower than the recommendation. Berndt et al.² report a somewhat faster rate constant than those obtained in the other studies based on competitive kinetics results with $\text{CH}_2\text{OO} + \text{SO}_2$ used as the reference reaction; these investigators employed the highly exothermic $\text{C}_2\text{H}_4 + \text{O}_3$ reaction to generate CH_2OO , suggesting that reactions of non-thermalized CH_2OO could impact the competitive kinetics results. Lewis et al. speculate that enhanced formation of $(\text{H}_2\text{O})_2$ in the mass spectrometer sampling region could have been a problem in the Berndt et al. study. Unlike earlier studies that employed $\text{O}_3 + \text{C}_2\text{H}_4$ as the CH_2OO source,^{1,11} Berndt et al. added propane to their reaction mixtures to scavenge OH radicals; this could explain why they observed a quadratic dependence of CH_2OO reactivity on $[\text{H}_2\text{O}]$ that was not observed in the earlier studies. The recommended uncertainty (f) is chosen so f^2 approximately brackets the results of the four experimental studies. The available experimental results, where a quadratic dependence of the CH_2OO loss rate on $[\text{H}_2\text{O}]$ is observed, do not distinguish between two possible reaction mechanisms: $\text{CH}_2\text{OO} + (\text{H}_2\text{O})_2 \rightarrow \text{Pr}$ or the two step process $\text{CH}_2\text{OO} + \text{H}_2\text{O} \rightarrow \text{X}$, followed by $\text{X} + \text{H}_2\text{O} \rightarrow \text{Pr}$. The theoretical results of Ryzhkov and Ariya^{7,8} provide strong support for the $\text{CH}_2\text{OO} + (\text{H}_2\text{O})_2$ pathway. Ryzhkov and Ariya have also theoretically examined the possible role of $(\text{H}_2\text{O})_3$ and $(\text{H}_2\text{O})_4$ in the atmospheric degradation of CH_2OO , and find these reactions to be much less important than $\text{CH}_2\text{OO} + (\text{H}_2\text{O})_2$.⁹ The theoretical work of Ryzhkov and Ariya,⁷ shows that CH_2OO interacts with $(\text{H}_2\text{O})_2$ to form hydrogen bonded ring complexes which isomerize rapidly to hydrogen bonded complexes of H_2O with hydroxymethyl hydroperoxide (HMHP, HOCH_2OOH) that are stable by $\sim 190 \text{ kJ mol}^{-1}$ relative to $\text{CH}_2\text{OO} + (\text{H}_2\text{O})_2$; as discussed theoretically by Crehuet et al.,⁴ these complexes can undergo unimolecular conversion to $\text{HCOOH} + 2 \text{H}_2\text{O}$ or $\text{H}_2\text{O}_2 + \text{H}_2\text{CO} + \text{H}_2\text{O}$. Theoretical analysis by Smith et al. confirms that the unusually large negative activation energy they observe experimentally is consistent with the mechanism described above.

D63. $\text{CH}_3\text{O}_2 + \text{O}_3$. This recommendation is from Tyndall et al.¹ Their recommendation is based mostly on the recent study by Tyndall et al.² The temperature dependence is based on the assumption that the only possible reaction which can occur is the O atom transfer from the CH_3O_2 radical and that the activation energy of $\sim 2 \text{ kcal mol}^{-1}$ for this O-atom transfer is similar to that in the $\text{HO}_2 + \text{O}_3$ reaction.

(Table: 02-25, Note: 02-25, Evaluated 02-25) [Back to Table](#)

- (1) Tyndall, G. S.; Cox, R. A.; Granier, C.; Lesclaux, R.; Moortgat, G. K.; Pilling, M. J.; Ravishankara, A. R.; Wallington, T. J. Atmospheric chemistry of small organic peroxy radicals. *J. Geophys. Res.* **2001**, *106*, 12157-12182.
- (2) Tyndall, G. S.; Wallington, T. J.; Ball, J. C. FTIR product study of the reactions $\text{CH}_3\text{O}_2 + \text{CH}_3\text{O}_2$ and $\text{CH}_3\text{O}_2 + \text{O}_3$. *J. Phys. Chem. A* **1998**, *102*, 2547-2554.

D64. $\text{CH}_3\text{O}_2 + \text{CH}_3\text{O}_2$. This recommendation is from Tyndall et al.¹ There are two confirmed sets of products for this reaction.

The relative product yield, k_a/k_b , was evaluated by Tyndall et al. to be $(26.2 \pm 6.6) \times \exp((-1130 \pm 240)/T)$. They concluded that there was no evidence for the formation of the CH_3OOCH_3 . The kinetics of this reaction have been studied by using UV absorption following pulsed photolytic production of the radicals. Tyndall et al. used the values of k/σ measured by a large number of groups along with the σ values from their evaluation to calculate k . (σ is the absorption cross section of the radical at the wavelength at which it was monitored.) They only used the kinetics data obtained at wavelengths larger than 240 nm, since the absorption by HO_2 radicals that are unavoidably produced in these measurements can significantly contribute to the measured UV profiles at shorter wavelengths. They noted that the values of k/σ measured by various groups were much more accurate than the values of σ measured by the same groups. The value of k obtained by this method was then corrected using the above branching ratio for the production of CH_3O that leads to the unavoidable occurrence of the $\text{CH}_3\text{O}_2 + \text{HO}_2$ side reaction; this side reaction consumes another CH_3O_2 radical.

(Table: 02-25, Note: 02-25, Evaluated 02-25) [Back to Table](#)

- (1) Tyndall, G. S.; Cox, R. A.; Granier, C.; Lesclaux, R.; Moortgat, G. K.; Pilling, M. J.; Ravishankara, A. R.; Wallington, T. J. Atmospheric chemistry of small organic peroxy radicals. *J. Geophys. Res.* **2001**, *106*, 12157-12182.

D65. $\text{CH}_3\text{O}_2 + \text{NO}$. This recommendation is from Tyndall et al.¹ They evaluated the available information to deduce that the main set of products under atmospheric conditions is $\text{CH}_3\text{O} + \text{NO}_2$. They noted, however, that a very small yield, <0.5%, of CH_3ONO_2 is also possible. The rate coefficient for the reaction at 298 K and its temperature dependence is based on numerous direct studies of this reaction that have been reported. (Table: 02-25, Note: 02-25, Evaluated 02-25) [Back to Table](#)

- (1) Tyndall, G. S.; Cox, R. A.; Granier, C.; Lesclaux, R.; Moortgat, G. K.; Pilling, M. J.; Ravishankara, A. R.; Wallington, T. J. Atmospheric chemistry of small organic peroxy radicals. *J. Geophys. Res.* **2001**, *106*, 12157-12182.

D66. $\text{CH}_3\text{O}_2 + \text{CH}_3\text{C}(\text{O})\text{O}_2$. This recommendation is from Tyndall et al.² This reaction has two sets of products:

Tyndall et al. reanalyzed the previously available data on the branching ratios for this reaction and concluded that the branching ratio for channel (a) was $k_a/k = 0.9 \pm 0.1$ and $k_b/k = 0.1 \pm 0.1$ at 298 K. They also concluded that branching ratios could not be derived for other temperatures from the existing data and therefore did not make a recommendation for the temperature dependence. The recommendation from Tyndall et al. is based on the work of Roehl et al.¹ and Villenave et al.³ Their recommended temperature dependence for the overall rate coefficient is based on analogy with other RO_2 reactions.

(Table: 02-25, Note: 02-25, Evaluated 02-25) [Back to Table](#)

D67. $\text{CH}_3\text{O}_2 + \text{CH}_3\text{C}(\text{O})\text{CH}_2\text{O}_2$. This recommendation is from Tyndall et al.³ This reaction has three possible sets of products:

The branching ratios for these channels, $k_a/k = 0.3 \pm 0.1$, $k_b/k = 0.2 \pm 0.1$, and $k_c/k = 0.5 \pm 0.1$, are based on the work of Bridier et al.¹ and Jenkin et al.² The overall rate coefficient for this reaction has been studied only at 298 K by Bridier et al. and the recommendation is based on this value. The recommended values of E/R and g are based on analogy with other RO_2 reactions.

(Table: 02-25, Note: 02-25, Evaluated 02-25) [Back to Table](#)

D68. $\text{C}_2\text{H}_5 + \text{O}_2$. This is a complex reaction that involves the formation of a $\text{C}_2\text{H}_5\text{O}_2$ adduct, which can either be stabilized by collisions or fall apart to HO_2 and C_2H_4 (Wagner et al.,³ Bozzelli and Dean,¹ and Kaiser et al.²). The fraction of the energized adducts that fall apart to give HO_2 and C_2H_4 will decrease with increasing pressure and decreasing temperature, i.e., as the $\text{C}_2\text{H}_5\text{O}_2$ formation increases. The C_2H_4 -formation channel cannot be separated from the addition reaction. We recommend a conservative upper limit as a guide to the extent of this reaction. This upper limit is applicable only for lower atmospheric pressure and temperature conditions.

D69. $\text{C}_2\text{H}_5\text{O} + \text{O}_2$. The recommendation is based on the pulsed laser photolysis studies of Gutman et al.¹ and Hartmann et al.² In both these studies, removal of $\text{C}_2\text{H}_5\text{O}$ in an excess of O_2 was directly monitored via laser induced fluorescence. Gutman et al. measured k at only two temperatures, while Hartmann et al. measured k at 5 temperatures between 295 and 411 K. The E/R is from Hartmann et al. The 298 K value deduced from an indirect study by Zabarnick and Heicklen³ is in reasonable agreement with the recommended value.

D70. CH_3CHOO (*syn* and *anti* conformers) + H_2O , $(\text{H}_2\text{O})_2$. Experimental measurements of k(298 K) have been reported by Taatjes et al.⁶ and Sheps et al.⁵ In both studies CH_3CHOO was produced by UV laser flash photolysis of $\text{CH}_3\text{CHI}_2/\text{O}_2$. Taatjes et al. monitored CH_3CHOO using time-resolved photoionization mass spectrometry; the *anti* and *syn* conformers could be differentiated in the detection scheme because they have different ionization potentials. Sheps et al. used time-resolved broadband (300–450 nm) cavity-enhanced spectrometry to monitor both conformers simultaneously; they determined spectra of the individual conformers based on their very different reactivities toward H_2O and SO_2 . Both studies employed relatively

low total pressures of 4 Torr O₂⁶ and 5–20 Torr He.⁵ The rate constant reported by Sheps et al. for reaction of the more reactive *anti* conformer with H₂O is over a factor of two faster than the one reported by Taatjes et al. In both studies, only upper limits could be obtained for the *syn*-CH₃CHOO + H₂O rate constant, with the Sheps et al. upper limit being a factor of twenty smaller than the Taatjes et al. upper limit. The Sheps et al. rate constants are recommended because their approach appears to provide better sensitivity and selectivity for detection of the individual conformers. The recommended uncertainty in the *anti*-CH₃CHOO + H₂O rate constant is somewhat larger than reported by Sheps et al. pending independent verification of their result.

The CH₃CHOO + water reactions have been studied theoretically by Anglada et al.,^{1,2} Ryzhkov and Ariya,⁴ and Kuwata et al.³ The more reactive *anti* conformer is found to lie 14–15 kJ mol⁻¹ higher in energy than the *syn* conformer.^{2,3} There is general agreement that reaction proceeds via initial formation of a hydrogen-bonded complex that isomerizes to the hydroxyl hydroperoxide CH₃CH(OH)OOH. The *syn* conformer is unreactive because the transition state for the isomerization reaction lies 22 kJ mol⁻¹ higher in energy than CH₃CHOO + H₂O reactants; for the *anti* conformer, isomerization takes place rapidly over a “submerged” barrier that lies 7 kJ mol⁻¹ lower in energy than reactants.² Rate constants for conversion of CH₃CHOO + H₂O to the hydroperoxide at T = 298 K and P = 1 atm are predicted in all four theoretical studies. There is general agreement that the *anti* conformer is more reactive than the *syn* conformer by factors of 4–7 × 10⁴. The most recent theoretical work² predicts a rate constant for *anti*-CH₃CHOO + H₂O that is a factor of 7 faster than the experimental value, whereas all three earlier theoretical studies predict *anti*-CH₃CHOO + H₂O rate constants that are substantially slower than the experimental value (factors of 10,¹ 35,⁴ and 80³).

To explain available experimental observations, there is no need to postulate the occurrence of a reaction of CH₃CHOO with (H₂O)₂. It should be pointed out, however, that the Taatjes et al. study was limited to P_{H₂O} ≤ 1.4 Torr and the Sheps et al. study was limited to P_{H₂O} ≤ 4.3 Torr. The data of Sheps et al. do show slight indication of upward curvature with increasing [H₂O] in the plot of the pseudo-first order *anti*-CH₃CHOO decay rate vs. [H₂O]. In their theoretical study, Ryzhkov and Ariya calculated rate constants for reactions of *syn*- and *anti*-CH₃CHOO with both H₂O and (H₂O)₂; they predict that at 298 K (H₂O)₂ is 1.0 × 10⁵ times more reactive than H₂O with the *syn* conformer and 4.2 × 10³ times more reactive with the *anti* conformer. For CH₂OO, where experimental evidence verifies the dominance of the (H₂O)₂ reaction, the reactivity ratio obtained theoretically by Ryzhkov and Ariya is 1.8 × 10⁵. Experiments at higher total pressures and higher H₂O partial pressures appear necessary for quantitatively assessing the importance of (H₂O)₂ reaction as a loss process for CH₃CHOO in the atmosphere.

D71. C₂H₅O₂ + C₂H₅O₂. k(298 K) has been studied by Adachi et al.,¹ Anastasi et al.,³ Munk et al.,⁸ Cattell et al.,⁵ Anastasi et al.,² Wallington et al.,¹⁰ Bauer et al.,⁴ and Fenter et al.⁶ All the above determinations used only UV absorption to monitor C₂H₅O₂ and hence measured k/σ, where σ is the absorption cross section of C₂H₅O₂ at the monitoring wavelength. These investigators also measured the σ that was used in evaluating the rate coefficient. There are large discrepancies in the measured values of σ. For this evaluation, we have used the cross sections recommended here and recalculated the values of k from each investigation. The recommended k is based on the results of Cattell et al., Wallington et al., Bauer et al., and Fenter et al. In all

these experiments the observed rate coefficient is higher than the true rate coefficient because of secondary reactions involving HO₂. HO₂ is formed by the reaction of CH₃CH₂O with O₂ and it reacts with C₂H₅O₂ to enhance the observed rate coefficient (see Wallington et al.¹¹ or Lightfoot et al.⁷ for further discussion). Based on product branching ratios discussed below, which determine the magnitude of the necessary correction, the recommended rate coefficient is 0.6 times the average observed rate coefficient. The recommended value of E/R was obtained from the results of Anastasi et al., Wallington et al., Cattell et al., Bauer et al., and Fenter et al. The observed products (Niki et al.⁹), suggest that at 298 K the channel to yield 2 C₂H₅O + O₂ accounts for about 60% of the reaction; the channel to yield CH₃CHO + C₂H₅OH + O₂ accounts for about 40% of the reaction; and the channel to yield C₂H₅O₂C₂H₅ + O₂ accounts for less than 5% of the reaction. These branching ratios were used to obtain the true rate coefficient from the observed rate coefficient.

D72. C₂H₅O₂ + NO. The recommended k(298 K) is obtained from the results of Plumb et al.,⁶ Sehested et al.,⁷ Daele et al.,³ Eberhard and Howard,⁴ and Maricq and Szente.⁵ The value reported by Adachi and Basco,¹ which is a factor of three lower than the recommended value, was not used. The rate coefficient for the CH₃O₂ + NO reaction measured by Basco and co-workers (Adachi et al.²) using the same apparatus is also much lower than the value recommended here. The recommended temperature dependence is derived from Eberhardt and Howard⁴ and Maricq and Szente,⁵ which are in good agreement.

D73. $\text{CH}_3\text{C}(\text{O})\text{O}_2 + \text{CH}_3\text{C}(\text{O})\text{O}_2$. This reaction has been studied by Addison et al.,¹ Basco and Parmar,² Moortgat et al.,⁴ Maricq and Szenté,³ and Roehl et al.,⁵ using UV absorption techniques. The recommended value is obtained from the data of Moortgat et al., Maricq and Szenté, and Roehl et al. As pointed out by Moortgat et al., the six times lower value of k obtained by Addison et al. is likely due to the use of incorrect UV absorption cross sections for the peroxy radical. The k obtained by Basco and Parmar is ~ 2 times lower than the recommended value. This discrepancy is possibly due to neglecting the UV absorption of CH_3O_2 and other stable products in their data analysis (Moortgat et al., Maricq and Szenté). The recommended temperature dependence was calculated from the data of Moortgat et al. and Maricq and Szenté. Addison et al. reported the formation of O_3 , which was attributed to the reaction channel that produces $\text{CH}_3\text{C}(\text{O})\text{OCH}_3\text{C}(\text{O}) + \text{O}_3$. Moortgat et al. place an upper limit of 2% for this channel. The main products of this reaction appear to be $\text{CH}_3\text{C}(\text{O})\text{O} + \text{O}_2$. The $\text{CH}_3\text{C}(\text{O})\text{O}$ radicals rapidly decompose to give CH_3 and CO_2 . (Table: 97-4, Note: 97-4, Evaluated 97-4) [Back to Table](#)

D74. $\text{CH}_3\text{C}(\text{O})\text{O}_2 + \text{NO}$. This recommendation is from Tyndall et al.¹ These authors have argued that the only set of products of importance in the atmosphere is the production of $\text{CH}_3 + \text{CO}_2 + \text{NO}_2$. This is because the alkoxy radical produced upon O abstraction from the peroxy radical by NO will be unstable towards decomposition to give CH_3 and CO_2 . The rate coefficient for the reaction was deduced primarily from direct studies, but was found to be consistent with the relative rate studies. In the relative rate studies, this rate coefficient was measured relative to the rate coefficient for the reaction of $\text{CH}_3\text{C}(\text{O})\text{O}_2$ with NO_2 . (Table: 02-25, Note: 10-6, Evaluated 10-6) [Back to Table](#)

- (1) Tyndall, G. S.; Cox, R. A.; Granier, C.; Lesclaux, R.; Moortgat, G. K.; Pilling, M. J.; Ravishankara, A. R.; Wallington, T. J. Atmospheric chemistry of small organic peroxy radicals. *J. Geophys. Res.* **2001**, *106*, 12157-12182.

D75. $\text{CH}_3\text{C}(\text{O})\text{CH}_2\text{O}_2 + \text{NO}$. This recommendation is from Tyndall et al.⁴ They deduced, based on the results of Sehested et al.,³ Jenkin et al.,¹ and Orlando et al.,² that the products of this reaction are $\text{CH}_3\text{C}(\text{O})\text{CH}_2\text{O} + \text{NO}_2$. The $\text{CH}_3\text{C}(\text{O})\text{CH}_2\text{O}$ radical decomposes rapidly to give $\text{CH}_3\text{C}(\text{O}) + \text{CH}_2\text{O}$. The only kinetics study of this reaction by Sehested et al. forms the basis for the rate coefficient at 298 K. This value is uncertain because of the corrections that had to be made in the study of Sehested et al. to account for the production of NO_2 , the monitored species, via the reaction of peroxy radicals (such as $\text{CH}_3\text{C}(\text{O})\text{O}_2$ and CH_3O_2) with NO. The temperature dependence of the reaction is derived based on analogy with other peroxy radical reactions. (Table: 02-25, Note: 02-25, Evaluated 02-25) [Back to Table](#)

Shaded areas indicate changes or additions since JPL10-6. Italicized [blue](#) entries denote estimates.

^a Temperature range of available experimental data. This is not necessarily the range of temperature over which the recommended Arrhenius parameters are applicable. See the corresponding note for each reaction for such information.

^b Units are cm³ molecule⁻¹ s⁻¹.

^c f(298 K) is the uncertainty factor at 298 K. To calculate the uncertainty at other temperatures, use the expression:

$$f(T) = f(298 \text{ K}) \exp \left| g \left(\frac{1}{T} - \frac{1}{298} \right) \right|$$

Note that the exponent is an absolute value.

1.10.2 Notes: FO_x Reactions

- E1. O + FO.** The recommended value for $k(298\text{ K})$ is based on results of the room temperature study of Bedzhanyan et al.¹ The temperature dependence of the rate constant is expected to be small, as it is for the analogous ClO reaction.
(Table: 94-26, Note: 94-26, Evaluated: 94-26) [Back to Table](#)
- (1) Bedzhanyan, Y. R.; Markin, E. M.; Politenkova, G. G.; Gershenzon, Y. M. Experimental study of elementary reactions of FO radicals. III. Reactions with oxygen and nitrogen atoms. *Kinetics and Catalysis* **1993**, 33, 797-801.
- E2. O + FO₂.** The recommended Arrhenius parameters are estimated, as there are no experimental data. The rate constant for such a radical-atom process is expected to approach the gas collision frequency, and is not expected to exhibit a strong temperature dependence.
(Table: 82-57, Note: 82-57, Evaluated: 82-57) [Back to Table](#)
- E3. OH + CH₃F (HFC-41).** The recommended value for $k(298\text{ K})$ is an average of the values from Schmoltner et al.,⁸ Nip et al.,⁷ Hsu and DeMore,⁴ and DeMore² (with the relative rate constants from the last two studies listed above recalculated based on the current recommendations for the rate constants for the OH + CH₃CHF₂ and OH + CH₃Cl reference reactions, respectively.) The recalculation procedure for relative rate measurements referenced to the OH + CH₃CHF₂ reaction is discussed in the note for that reaction. The recommended value for E/R is an average of the values obtained in the studies of Schmoltner et al.,⁸ Hsu and DeMore,⁴ and DeMore.² The results of Howard and Evenson,³ Jeong and Kaufman,⁵ Bera and Hanrahan,¹ and Wallington and Hurley⁹ appear to be systematically lower than those of the other studies over the temperature region of interest and were not used to derive the recommended parameters. The results from the 298 K study by Kowalczyk et al.,⁶ although in good agreement with the recommended value for $k(298\text{ K})$, also were not used since the results reported in this study for several halocarbons vary widely (ranging from 10% agreement with recommendations to as much as 3 orders of magnitude disagreement with recommendations).

E5. OH + CHF₃ (HFC-23). The recommended value for k(298 K) is an average of the values reported in the absolute rate study of Schmoltner et al.⁹ and in the relative rate studies of Hsu and DeMore⁵ (recalculated based on the current recommendation for the rate constant for the OH + CHF₂CF₃ reference reaction) and of Chen et al.² (two relative rate determinations recalculated based on the current recommendations for the rate constants for the OH + CHF₂CF₃ and OH + CHF₂Cl reference reactions). The recommended value for E/R is derived from a fit to the data from these same three studies after scaling each data set to the recommended value of k(298 K). The results of Jeong and Kaufman⁶ and Medhurst et al.,⁷ being predominantly above room temperature, were not used in deriving the recommended parameters. The results from Clyne and Holt³ and Bera and Hanrahan¹ were also not used due to their inconsistency with the other studies. The room temperature values of Howard and Evenson⁴ and Nip et al.⁸ are encompassed within the 2σ confidence limits. (Table: 15-10, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

E6. OH + CH₃CH₂F (HFC-161). The recommended value for k(298 K) is an average of the values from Nip et al.,³ Schmoltner et al.,⁴ and Kozlov et al.² The value of E/R is derived from a fit to the data from the latter two studies at room temperature and below after scaling each data set to the value recommended for k(298 K). The relative rate study by Hsu and DeMore¹ reports a temperature dependence that is markedly stronger than those of Schmoltner et al.⁴ and Kozlov et al.,² which are in excellent agreement. This difference is due to significantly lower rate constant values being in the Hsu and DeMore study in the region near room temperature. The Hsu and DeMore temperature dependence for HFC-161 is also significantly stronger than measured and recommended for HFC-152 and HFC-152a, where similar dependences would be expected. Curvature in the Arrhenius plot is evident from the study by Kozlov et al.,² which was conducted over an extended temperature range above and below room temperature. Singleton et al.⁵ determined that 85 ± 3% of the abstraction by OH is from the fluorine-substituted methyl group at room temperature. Hence, curvature in the Arrhenius plot may be due to the increasing importance of hydrogen abstraction from the unsubstituted methyl group with increasing temperature, although similar curvature was observed in the case of OH + CH₂FCH₂F with two identical fluoromethyl groups. Due to such curvature, the recommended Arrhenius parameters should not be used for calculating rate constants above room temperature. Rather, one should use the three-parameter expression that is derived from a fit to the data of Kozlov et al. over the temperature range from 210 K to 480 K after the data were scaled to match the recommended value of k(298 K):

$$k(T) = 3.1 \times 10^{-13} (T/298)^{2.45} \exp(-103/T)$$

E7. OH + CH₃CHF₂ (HFC-152a). The recommended value for k(298 K) is an average of the values from the absolute rate studies of Howard and Evenson,⁵ Handwerk and Zellner,⁴ Nip et al.,¹⁰ Gierczak et al.³ (two different determinations), and Kozlov et al.,⁷ and from the relative rate studies of Hsu and DeMore⁶ (two determinations that have been recalculated based on the current recommendations for the rate constants of the OH + CH₄ and OH + CH₃CCl₃ reference reactions), Wilson et al.¹² (two determinations that have been recalculated based on the current recommendations for the rate constants of the OH + C₂H₆ and OH + *c*-C₃H₈ reference reactions), and Taketani et al.¹¹ (two determinations that have been recalculated based on the current recommendations for the rate constants of the OH + C₂H₂ and OH + C₂H₄ reference reactions). There are systematic differences in the temperature dependencies determined in the absolute studies (particularly below room temperature) and relative studies (conducted at room temperature and above). Curvature in the Arrhenius plot (as suggested by the data of Gierczak et al.³) has been more clearly demonstrated in the study of Kozlov et al.⁷ and seems to explain the earlier cited differences between the relative and absolute rate data. This curvature may be due to the presence of two hydrogen-abstraction reaction channels, although similar curvature was observed in case of OH + CH₂FCH₂F with two identical fluoromethyl groups. Hence, care must be taken in deriving a recommended rate expression suitable for atmospheric modeling (in the temperature region below room temperature).

In spite of the noticeable Arrhenius curvature over the temperature range from 210 K to 480 K, the data below 300 K can be well represented by a two-parameter Arrhenius expression. Thus, the recommended value for E/R is derived from a combined fit to the data ($T \leq 300$ K) of Gierczak et al.³ and Kozlov et al.⁷ after scaling each data set to the recommended value for $k(298$ K). The studies by Clyne and Holt,² Brown et al.,¹ and Nielsen⁹ all yield systematically higher rate constants and were not used in deriving the recommended parameters. The study by Liu et al.⁸ is superseded by that of Kozlov et al.⁷ In light of the observed Arrhenius curvature, the Arrhenius parameters recommended for temperatures below 300 K are not suitable for use in recalculating rate constants from relative rate studies conducted at temperatures above 300 K in which the OH + CH₃CHF₂ reaction was the reference. For such purposes, we recommend use of the three-parameter expression derived from a fit to the data of Kozlov et al.⁷ over the temperature range from 210 K to 480 K after the data were scaled to match the recommended value of $k(298$ K):

$$k(T) = 7.57 \times 10^{-14} (T/298)^{3.02} \exp(-247/T)$$

The site-specific rate coefficients were estimated by Kozlov et al.⁷ (assuming that the observed curvature in the Arrhenius plot is entirely due to different reaction channels) to be 33% reaction at the CH₃ group and 67% H atom abstraction from the CHF₂ group.

E8. OH + CH₂FCH₂F (HFC-152). The recommended value for $k(298$ K) is an average of the values from the absolute rate studies of Martin and Paraskevopoulos² and Kozlov et al.¹ and from the relative rate studies of Wilson et al.³ (three determinations recalculated using the current recommendations for the reference reactions of OH with HFC-152a, cyclopropane, and ethane). The value for E/R is from a fit to the data of Kozlov et al.¹ at room temperature and below. The data above room temperature from Kozlov et al.¹ are in excellent agreement with the three relative rate data sets of Wilson et al.³ Together, they show a pronounced curvature in the Arrhenius plot, which may indicate the existence of different conformers for HFC-152, each

with differing temperature populations and reactivities. The data over the temperature range from 210 K to 480 K can be represented by the three-parameter expression from Kozlov et al. after the latter was scaled to match the recommended $k(298\text{ K})$:

$$k(T) = 4.23 \times 10^{-14} (T/298)^{3.85} \exp(+247/T)$$

(Table: 10-6, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

- (1) Kozlov, S. N.; Orkin, V. L.; Kurylo, M. J. An investigation of the reactivity of OH with fluoroethanes: $\text{CH}_3\text{CH}_2\text{F}$ (HFC-161), $\text{CH}_2\text{FCH}_2\text{F}$ (HFC-152), and CH_3CHF_2 (HFC-152a). *J. Phys. Chem. A* **2003**, *107*, 2239-2246, doi:10.1021/jp022087b.

E9. OH + CH_3CF_3 (HFC-143a). The recommended value for $k(298\text{ K})$ is an average of the values from the absolute rate studies of Orkin et al.⁴ and Talukdar et al.⁵ (two different determinations by DF-LMR and LP-LIF), and from the relative rate study of Hsu and DeMore² (two determinations that have been recalculated based on the current recommendations for the rate constants of the OH + CH_4 and OH + CHF_2CF_3 reference reactions). The value for E/R is from a combined fit of the data from these three studies after scaling each data set to the recommended value for $k(298\text{ K})$. The data of Clyne and Holt¹ (333–425 K) and from Martin and Paraskevopoulos³ (298 K) were not used due to their inconsistency with the other studies.

Chem.* **1991**, *95*, 5815-5821.

E10. OH + CH_2FCHF_2 (HFC-143). The recommended value for $k(298\text{ K})$ is an average of the room temperature values of Martin and Paraskevopoulos³ and Barry et al.¹ The recommended temperature dependence is based on results of the relative rate study of Barry et al.,¹ which have been recalculated based on the current recommendation for the rate constant of the reference reaction OH + CH_3CCl_3 . The significantly higher values reported by Clyne and Holt² were not used in the derivation of the recommended parameters.

(Table: 02-25, Note: 02-25, Evaluated: 02-25) [Back to Table](#)

- (1) Barry, J.; Sidebottom, H.; Treacy, J.; Franklin, J. Kinetics and mechanism for the atmospheric oxidation of 1,1,2-trifluoroethane (HFC 143). *Int. J. Chem. Kinet.* **1995**, *27*, 27-36.
- (2) Clyne, M. A. A.; Holt, P. M. Reaction kinetics involving ground $X^2\Pi$ and excited $A^2\Sigma^+$ hydroxyl radicals Part 2.-Rate constants for reactions of OH $X^2\Pi$ with halogenomethanes and halogenoethanes. *J. Chem. Soc. Faraday Trans. 2* **1979**, *75*, 582-591.
- (3) Martin, J.-P.; Paraskevopoulos, G. A kinetic study of the reactions of OH radicals with fluoroethanes. Estimates of C-H bond strengths in fluoroalkanes. *Can. J. Chem.* **1983**, *61*, 861-865.

E11. OH + CH_2FCF_3 (HFC-134a). The recommended value for $k(298\text{ K})$ is an average of the values derived from the absolute rate studies of Gierczak et al.⁵ (two determinations using discharge flow and pulsed photolysis), Leu and Lee,⁷ Liu et al.,⁸ and Orkin and Khamaganov,¹⁰ from the relative rate study of DeMore⁴ (three determinations that have been recalculated based on the current recommendations for the rate constants of the reference reactions OH + CH_4 , OH + CH_3CCl_3 , and OH + CHF_2CF_3), and from the room temperature investigations of Bednarek et al.¹ and Martin and Paraskevopoulos.⁹ The value for E/R is derived from a combined fit ($T \leq 400\text{ K}$) to the data from the first five investigations listed above after each data set was

scaled to the recommended value of $k(298\text{ K})$, together with the single determination at $T = 270\text{ K}$ by Zhang et al.¹¹ The data from Liu et al.⁸ above 350 K were excluded from the combined fit since they significantly exceed the results from the other studies at these temperatures, and subsequent experiments from the same laboratory have demonstrated that a systematic underestimation of the reaction cell temperature above 350 K may have been responsible. The data at 243 K and 223 K from the pulsed photolysis – LIF study by Gierczak et al.⁵ were also excluded from the combined fit since this data set (obtained at $T < 298\text{ K}$) exhibits a substantially weaker Arrhenius temperature dependence ($E/R = 1310\text{ K}$) when compared with that from other studies conducted mainly above $T = 270\text{ K}$. This could be indicative of curvature in the Arrhenius plot at lower temperatures. Nevertheless, the “g” uncertainty factor was selected to encompass these low temperature data. The data of Brown et al.,² Clyne and Holt³ and Jeong et al.⁶ are considerably higher than those from all other studies and were not used in deriving the recommended parameters.

E12. OH + CHF_2CHF_2 (HFC-134). The recommended Arrhenius parameters are based on results of the three relative rate measurements by DeMore,² which have been recalculated based on the current rate constant recommendations for the $\text{OH} + \text{CH}_3\text{CCl}_3$, $\text{OH} + \text{CH}_2\text{FCF}_3$, and $\text{OH} + \text{CHF}_2\text{CF}_3$ reference reactions. The room temperature value of Clyne and Holt¹ agrees within the 2σ confidence limits.

E13. OH + CHF_2CF_3 (HFC-125). The recommended value for $k(298\text{ K})$ is an average of values derived from the data of Talukdar et al.,⁵ DeMore,³ and Young et al.⁶ The recommended value for E/R was taken from Talukdar et al. The temperature dependent data of Brown et al.¹ and Clyne and Holt² were not used in deriving the recommended parameters since they exhibit considerable scatter and the derived rate constants are systematically higher than those from the other studies, which may be indicative of impurity effects. The room temperature data of Martin and Paraskevopoulos⁴ were not included in the $k(298\text{ K})$ average for similar reasons.

Phys. Lett.* **2009**, 473, 251-256, doi:10.1016/j.cplett.2009.04.001.

E14. OH + $\text{CH}_3\text{CHFCH}_3$ (HFC-281ea). The recommended value for $k(298\text{ K})$ is an average of values derived from fits to each of five relative rate data sets of DeMore and Wilson¹ (using infrared detection with C_2H_6 , C_3H_8 , and $\text{C}_2\text{H}_5\text{Cl}$ as reference compounds and gas chromatography with C_2H_6 and C_3H_8 as reference compounds). All of the data were recalculated based on the current recommendations for the rate constants of the reference compounds reacting with OH. The recommended value for E/R is derived from the combined fit to all data from this study after each data set was scaled to the recommended value of $k(298\text{ K})$.

(Table: 02-25, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

- (1) DeMore, W. B.; Wilson, E. W., Jr. Rate constant and temperature dependence for the reaction of hydroxyl radicals with 2-fluoropropane (HFC-281ea). *J. Phys. Chem. A* **1999**, 103, 573-576.

E15. OH + $\text{CH}_3\text{CH}_2\text{CF}_3$ (HFC-263fb). The recommended value for $k(298\text{ K})$ is an average of the values reported by Nelson et al.¹ and by Rajakumar et al.² The temperature dependence is from a fit to the data of Rajakumar et al.²

(Table: 10-6, Note: 10-6, Evaluated: 10-6) [Back to Table](#)

- (1) Nelson, D. D.; Zahniser, M. S.; Kolb, C. E.; Magid, H. OH reaction kinetics and atmospheric lifetime estimates for several hydrofluorocarbons. *J. Phys. Chem.* **1995**, 99, 16301-16306, doi:10.1021/j100044a016.
- (2) Rajakumar, B.; Portmann, R. W.; Burkholder, J. B.; Ravishankara, A. R. Rate coefficients for the reactions of OH with $\text{CF}_3\text{CH}_2\text{CH}_3$ (HFC-263fb), $\text{CF}_3\text{CHFCH}_2\text{F}$ (HFC-245eb), and $\text{CHF}_2\text{CHFCHF}_2$ (HFC-245ea) between 238 and 375 K. *J. Phys. Chem. A* **2006**, 110, 6724 - 6731, doi:10.1021/jp056248y.

E16. OH + $\text{CH}_2\text{FCF}_2\text{CHF}_2$ (HFC-245ca). There is an approximate 50% difference between the absolute rate constant results of Zhang et al.² and those derived from the relative rate data of Hsu and DeMore¹ (recalculated using the current recommendation for the rate constant of the OH + CH_4 reference reaction) over the common temperature region of the measurements. Both data sets, however, exhibit nearly identical temperature dependencies. The recommended value for $k(298\text{ K})$ is an average of the values from both studies. The recommended value for E/R is derived from a combined fit to the data from both studies after each data set was scaled to the recommended value of $k(298\text{ K})$.

- (1) Hsu, K. J.; DeMore, W. B. Rate constants and temperature dependences for the reactions of hydroxyl radical with several halogenated methanes, ethanes, and propanes by relative rate measurements. *J. Phys. Chem.* **1995**, 99, 1235-1244.
- (2) Zhang, Z.; Padmaja, S.; Saini, R. D.; Huie, R. E.; Kurylo, M. J. Reactions of hydroxyl radicals with several hydrofluorocarbons: The temperature dependencies of the rate constants for $\text{CHF}_2\text{CF}_2\text{CH}_2\text{F}$ (HFC-245ca), $\text{CF}_3\text{CHFCHF}_2$ (HFC-236ea), $\text{CF}_3\text{CHF}_2\text{CF}_3$ (HFC-227ea), and $\text{CF}_3\text{CH}_2\text{CH}_2\text{CF}_3$ (HFC-356ffa). *J. Phys. Chem.* **1994**, 98, 4312-4315, doi:10.1021/j100067a017.

E17. OH + CH₃CF₂CF₃ (HFC-245cb). The recommended Arrhenius parameters are based on the data of Orkin et al.¹ The Arrhenius parameters for this reaction are expected to be similar to those for OH + CH₃CF₃ (HFC-143a). Hence, the 95% confidence limits have been selected to encompass the recommendation for the latter reaction.

(Table: 15-10, Note: 15-10), Evaluated: 15-10) [Back to Table](#)

- (1) Orkin, V. L.; Huie, R. E.; Kurylo, M. J. Rate constants for the reactions of OH with HFC-245cb (CH₃CF₂CF₃) and some fluoroalkenes (CH₂CHCF₃, CH₂CFCF₃, CF₂CFCF₃, and CF₂CF₂). *J. Phys. Chem. A* **1997**, *101*, 9118-9124.

E18. OH + CHF₂CHFCHF₂ (HFC-245ea). Nelson et al.¹ measured the room temperature rate constant for this reaction. Rajakumar et al.² studied the temperature dependence in experiments conducted above and below room temperature. However, this study was complicated by the presence of a reactive impurity, as demonstrated by some additional low temperature results obtained with a purified sample. The recommended value for E/R was derived from a fit to the original data from Rajakumar et al.² corrected for the effect of reactive impurities at T ≥ 298 K and the data obtained with the purified sample below 298 K. The recommended value for k(298 K) is an average of the value obtained from this fit and the value reported by Nelson et al.,¹ which are in excellent agreement.

(Table: 10-6, Note: 10-6, Evaluated: 10-6) [Back to Table](#)

- (1) Nelson, D. D.; Zahniser, M. S.; Kolb, C. E.; Magid, H. OH reaction kinetics and atmospheric lifetime estimates for several hydrofluorocarbons. *J. Phys. Chem.* **1995**, *99*, 16301-16306, doi:10.1021/j100044a016.
- (2) Rajakumar, B.; Portmann, R. W.; Burkholder, J. B.; Ravishankara, A. R. Rate coefficients for the reactions of OH with CF₃CH₂CH₃ (HFC-263fb), CF₃CHFCH₂F (HFC-245eb), and CHF₂CHFCHF₂ (HFC-245ea) between 238 and 375 K. *J. Phys. Chem. A* **2006**, *110*, 6724 - 6731, doi:10.1021/jp056248y.

E19. OH + CH₂FCHFCH₂CF₃ (HFC-245eb). The recommended value for k(298 K) is an average of the values reported by Nelson et al.¹ and by Rajakumar et al.² The recommended value for E/R was derived from a fit to the data from Rajakumar et al.²

(Table: 10-6, Note: 10-6, Evaluated: 10-6) [Back to Table](#)

- (1) Nelson, D. D.; Zahniser, M. S.; Kolb, C. E.; Magid, H. OH reaction kinetics and atmospheric lifetime estimates for several hydrofluorocarbons. *J. Phys. Chem.* **1995**, *99*, 16301-16306, doi:10.1021/j100044a016.
- (2) Rajakumar, B.; Portmann, R. W.; Burkholder, J. B.; Ravishankara, A. R. Rate coefficients for the reactions of OH with CF₃CH₂CH₃ (HFC-263fb), CF₃CHFCH₂F (HFC-245eb), and CHF₂CHFCHF₂ (HFC-245ea) between 238 and 375 K. *J. Phys. Chem. A* **2006**, *110*, 6724 - 6731, doi:10.1021/jp056248y.

E20. OH + CHF₂CH₂CF₃ (HFC-245fa). The recommended value for k(298 K) is an average of values reported by Orkin et al.² and Nelson et al.,¹ which are in good agreement. The temperature dependence is from Orkin et al.

(Table: 15-10, Note: 02-25, Evaluated: 15-10) [Back to Table](#)

- (1) Nelson, D. D.; Zahniser, M. S.; Kolb, C. E.; Magid, H. OH reaction kinetics and atmospheric lifetime estimates for several hydrofluorocarbons. *J. Phys. Chem.* **1995**, *99*, 16301-16306, doi:10.1021/j100044a016.
- (2) Orkin, V. L.; Huie, R. E.; Kurylo, M. J. Atmospheric lifetimes of HFC-143a and HFC-245fa. *J. Phys. Chem.* **1996**, *100*, 8907-8912, doi:10.1021/jp9601882.

E21. OH + CH₂FCF₂CF₃ (HFC-236cb). The recommended rate expression is estimated as being the same as that for the reaction of OH with CH₂FCF₃ (HFC-134a), since these reactions are expected to have similar Arrhenius parameters. This estimate is preferred over the results reported by Garland et al.,¹ the only published experimental study. The A-factor reported in that study is much lower than expected, and the reported E/R = 1107 K is lower than that reported for any similar halocarbon reaction.

(Table: 15-10, Note: 10-6, Evaluated: 15-10) [Back to Table](#)

- (1) Garland, N. L.; Medhurst, L. J.; Nelson, H. H. Potential chlorofluorocarbon replacements: OH reaction rate constants between 250 and 315 K and infrared absorption spectra. *J. Geophys. Res.* **1993**, *98*, 23107-23111.

E22. OH + CHF₂CHFCF₃ (HFC-236ea). The recommended value for k(298 K) is an average of the values from the relative rate study of Hsu and DeMore² (recalculated based on the current recommendation for the rate constant of the OH + CH₄ reference reaction) and from the absolute study of Nelson et al.³ The temperature dependence is from Hsu and DeMore.² The higher and somewhat more scattered values of Garland et al.¹ and Zhang et al.⁴ were not used in deriving the recommended expression.

(Table: 02-25, Note: 02-25, Evaluated: 02-25) [Back to Table](#)

- (1) Garland, N. L.; Medhurst, L. J.; Nelson, H. H. Potential chlorofluorocarbon replacements: OH reaction rate constants between 250 and 315 K and infrared absorption spectra. *J. Geophys. Res.* **1993**, *98*, 23107-23111.
- (2) Hsu, K. J.; DeMore, W. B. Rate constants and temperature dependences for the reactions of hydroxyl radical with several halogenated methanes, ethanes, and propanes by relative rate measurements. *J. Phys. Chem.* **1995**, *99*, 1235-1244.
- (3) Nelson, D. D.; Zahniser, M. S.; Kolb, C. E.; Magid, H. OH reaction kinetics and atmospheric lifetime estimates for several hydrofluorocarbons. *J. Phys. Chem.* **1995**, *99*, 16301-16306, doi:10.1021/j100044a016.
- (4) Zhang, Z.; Padmaja, S.; Saini, R. D.; Huie, R. E.; Kurylo, M. J. Reactions of hydroxyl radicals with several hydrofluorocarbons: The temperature dependencies of the rate constants for CHF₂CF₂CH₂F (HFC-245ca), CF₃CHFCF₂ (HFC-236ea), CF₃CHFCF₃ (HFC-227ea), and CF₃CH₂CH₂CF₃ (HFC-356ffa). *J. Phys. Chem.* **1994**, *98*, 4312-4315, doi:10.1021/j100067a017.

E23. OH + CF₃CH₂CF₃ (HFC-236fa). The recommended rate expression is derived from a combined fit to the data from the relative rate study of Hsu and DeMore⁵ (recalculated based on the current recommendation for the rate constant of the reference reaction OH + CHF₂CF₃) and from the absolute rate study of Gierczak et al.⁴ The higher results of Nelson et al.⁶ and of Garland and Nelson,³ which superseded the earlier results of Garland et al.² were not used. A relative rate determination at room temperature by Barry et al.¹ yields a rate constant in excellent agreement with the recommended value. However, the extremely small measured rate constant ratio (due to the use of OH + CH₃CF₂CH₂CF₃ as the reference) is associated with fairly large uncertainty. Hence, this determination was not directly used in the evaluation.

E24. OH + CF₃CHFCF₃ (HFC-227ea). The recommended value for k(298 K) is the average of values derived from the absolute rate studies of Nelson et al.,² Zellner et al.,⁵ Zhang et al.,⁶ and Tokuhashi et al.,³ and from the relative rate studies of Hsu and DeMore¹ (two determinations that have been recalculated based on the current recommendations for the rate constants of the reference reactions OH + CH₄ and OH + CHF₂CF₃) and Wallington et al.⁴ (two determinations that have been recalculated based on the current recommendations for the rate constants of the reference reactions OH + C₂H₄ and OH + C₂H₂). The recommended value for E/R is

derived from a fit to the data below 400 K reported by Nelson et al.,² Zellner et al.,⁵ Tokuhashi et al.,³ and Hsu and DeMore¹ after scaling each data set to the recommended value for k(298 K).

Phys. Chem.* **1994**, 98, 4312-4315, doi:10.1021/j100067a017.

E27. OH + CH₂FCH₂CF₂CF₃ (HFC-356mcf). The recommended values for both k(298 K) and E/R are based on the data of Nelson et al.¹

(Table: 02-25, Note: 02-25, Evaluated: 02-25) [Back to Table](#)

- (1) Nelson, D. D.; Zahniser, M. S.; Kolb, C. E.; Magid, H. OH reaction kinetics and atmospheric lifetime estimates for several hydrofluorocarbons. *J. Phys. Chem.* **1995**, 99, 16301-16306, doi:10.1021/j100044a016.

E28. OH + CHF₂CF₂CF₂CF₂H (HFC-338pcc). The recommended value for k(298 K) is an average of values derived from fits to the data of Schmoltner et al.¹ and Zhang et al.² The recommended value for E/R is

derived from the combined fit to the data from both studies after each data set was scaled to the recommended value of $k(298\text{ K})$.

(Table: 02-25, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

E29. OH + CF₃CH₂CF₂CH₂CF₃ (HFC-458mfcf). The recommended values for both $k(298\text{ K})$ and E/R are based on the data of Nelson et al.¹

(Table: 02-25, Note: 02-25, Evaluated: 02-25) [Back to Table](#)

- (1) Nelson, D. D.; Zahniser, M. S.; Kolb, C. E.; Magid, H. OH reaction kinetics and atmospheric lifetime estimates for several hydrofluorocarbons. *J. Phys. Chem.* **1995**, 99, 16301-16306, doi:10.1021/j100044a016.

E30. OH + CF₃CHFCHFCF₂CF₃ (HFC-43-10mee). The recommended value for $k(298\text{ K})$ is an average of values derived from absolute studies by Schmoltner et al.¹ and Zhang et al.² The recommended value for E/R is derived from a combined fit to the data from Schmoltner et al. and Zhang et al. after scaling each data set to the recommended value for $k(298\text{ K})$.

(Table: 02-25, Note: 02-25, Evaluated: 02-25) [Back to Table](#)

- (1) Schmoltner, A. M.; Talukdar, R. K.; Warren, R. F.; Mellouki, A.; Goldfarb, L.; Gierczak, T.; McKeen, S. A.; Ravishankara, A. R. Rate coefficients for reactions of several hydrofluorocarbons with OH and O(¹D) and their atmospheric lifetimes. *J. Phys. Chem.* **1993**, 97, 8976-8982.
- (2) Zhang, Z.; Saini, R. D.; Kurylo, M. J.; Huie, R. E. Rate constants for the reactions of the hydroxyl radical with CHF₂CF₂CF₂CHF₂ and CF₃CHFCHFCF₂CF₃. *Chem. Phys. Lett.* **1992**, 200, 230-234.

E31. OH + CF₃CF₂CH₂CH₂CF₂CF₃ (HFC-55-10mcff). The recommended value for $k(298\text{ K})$ is that reported by Nelson et al.¹ As expected, the rate constant is similar to that for OH + CF₃CH₂CH₂CF₃. Hence, the recommendation for E/R is estimated as being approximately the same as that for this reaction.

(Table: 02-25, Note: 02-25, Evaluated: 02-25) [Back to Table](#)

- (1) Nelson, D. D.; Zahniser, M. S.; Kolb, C. E.; Magid, H. OH reaction kinetics and atmospheric lifetime estimates for several hydrofluorocarbons. *J. Phys. Chem.* **1995**, 99, 16301-16306, doi:10.1021/j100044a016.

E32. OH + CH₂=CHF. The recommended values for $k(298\text{ K})$ and E/R are from the absolute study by Baasandorj et al.¹ Data from the relative rate study by Chen et al.² are in reasonable agreement with the recommendation but are significantly more scattered. Baasandorj et al. found the rate constant to be pressure independent between 20 and 600 Torr, indicating that the high-pressure limit was achieved at these pressures for the reaction of this fluorinated alkene. Since this is the simplest of the halogenated alkenes, it implies that the recommendations for all of the halogenated alkene reactions included in Table 1 represent the high-pressure limits for the rate constants. The results of Perry et al.³ are ~10% larger at room temperature, with the agreement improving above room temperature. These data are encompassed within the recommended uncertainty.

(Table: 15-10, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

- E33. OH + CH₂=CF₂.** The recommended value for k(298 K) is an average of values derived from the absolute study by Baasandorj et al.¹ and the relative rate study by Chen et al.² The value recommended for E/R is derived from a combined fit to the data from Baasandorj et al. and Chen et al.² after scaling each data set to the recommended value for k(298 K). Baasandorj et al. found the rate constant to be pressure independent between 20 and 600 Torr, indicating that the high-pressure limit was achieved for the reaction of this fluorinated alkene. Howard³ studied this reaction at lower pressures and found a smaller rate constant that increased with pressure between 0.7 Torr and 7 Torr. This dependence is consistent with the recommended high pressure limit from Baasandorj et al.
(Table: 15-10, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

- E36. OH + CH₂=CHCH₂F.** The recommended values for both k(298 K) and E/R are derived from a fit to the data from the absolute study by Albaladejo et al.¹ Based on results obtained for other fluorinated alkenes the recommended rate constant represents the high-pressure limit for this reaction.
(Table: 10-6, Note: 10-6, Evaluated: 10-6) [Back to Table](#)
- (1) Albaladejo, J.; Ballesteros, B.; Jimenez, E.; Diaz de Mera, Y.; Martinez, E. Gas-phase OH radical-initiated oxidation of the 3-halopropenes studied by PLP-LIF in the temperature range 228-388 K. *Atmos. Environ.* **2003**, *37*, 2919-2926, doi:10.1016/S1352-2310(03)00297-8.
- E37. OH + CH₂=CHCF₃.** The recommended value for k(298 K) is an average of the values from the absolute rate constant measurements by Orkin et al.² and González et al.¹ The room temperature results from the two relative rate studies by Sulbaek Andersen et al.³ (recalculated using the current recommendations for the reference reactions OH + C₂H₄ and OH + C₂H₂) are somewhat lower but are encompassed within the combined reported uncertainties. The recommended value for E/R is derived from a combined fit to the data from Orkin et al.³ and González et al.¹ after scaling each data set to the recommended value for k(298 K).

González et al. found the rate constant to be pressure independent between 50 and 650, Torr indicating that the recommended rate constant represents the high-pressure limit for this reaction.

E38. OH + CH₂=CFCF₃. The results of absolute reaction rate studies by Orkin et al.,² Papadimitriou et al.,⁴ and Orkin et al.³ agree to better than 3% over the entire common temperature range of measurements between 220 K to 370 K. The recommended Arrhenius parameters are derived from a combined fit at T ≤ 300 K to the data of Papadimitriou et al.⁴ and Orkin et al.,³ which supersedes Orkin et al.² and has higher reported accuracy. The two relative rate determinations at 298 K by Nielsen et al.¹ (recalculated using the current rate constant recommendations for the reference reactions OH + C₂H₄ and OH + C₂H₂) lie outside the 95% uncertainty band assigned to k(298 K). Papadimitriou et al.⁴ found the rate constant to be pressure independent between 25 and 600 Torr and Orkin et al.³ found the rate constant to be pressure independent between 30 and 300 Torr, indicating that the high-pressure limit is achieved for this reaction. The data at above room temperature exhibit slight curvature in the Arrhenius plot.

- (2) Orkin, V. L.; Huie, R. E.; Kurylo, M. J. Rate constants for the reactions of OH with HFC-245cb (CH₃CF₂CF₃) and some fluoroalkenes (CH₂CHCF₃, CH₂CFCF₃, CF₂CFCF₃, and CF₂CF₂). *J. Phys. Chem. A* **1997**, *101*, 9118-9124.
- (3) Orkin, V. L.; Martynova, L. E.; Ilichev, A. N. High-accuracy measurements of OH reaction rate constants and IR absorption spectra: CH₂=CF-CF₃ and *trans*-CHF=CH-CF₃. *J. Phys. Chem. A* **2010**, *114*, 5967-5979, doi:10.1021/jp9092817.
- (4) Papadimitriou, V. C.; Talukdar, R. K.; Portmann, R. W.; Ravishankara, A. R.; Burkholder, J. B. CF₃CF=CH₂ and (Z)-CF₃CF=CHF: temperature dependent OH rate coefficients and global warming potentials. *Phys. Chem. Chem. Phys.* **2008**, *10*, 808-820, doi:10.1039/b714382f.

E39. OH + (E)-CHF=CHCF₃. The data obtained by Orkin et al.¹ exhibit a very weak temperature dependence and curvature in the Arrhenius plot between 370 K and 220 K. The recommended values for both k(298 K) and E/R are derived from a fit to the data of Orkin et al. at T ≤ 300 K. Orkin et al. found the rate constant to be pressure independent between 30 and 200 Torr, indicating that the high-pressure limit is achieved for this reaction. The two relative rate determinations at 298 K by Sondergaard et al.² (recalculated using the current recommendations for the rate constants of the reference reactions OH + C₂H₄ and OH + C₂H₂) lie about 20% higher than the recommended value. The data over the temperature range from 220 K to 370 K can be better represented by the three-parameter expression from Orkin et al.

$$k(T) = 1.12 \times 10^{-13} (T/298)^{2.03} \exp(+552/T)$$

(Table: 10-6, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

- (1) Orkin, V. L.; Martynova, L. E.; Ilichev, A. N. High-accuracy measurements of OH reaction rate constants and IR absorption spectra: CH₂=CF-CF₃ and *trans*-CHF=CH-CF₃. *J. Phys. Chem. A* **2010**, *114*, 5967-5979, doi:10.1021/jp9092817.
- (2) Sondergaard, R.; Nielsen, O. J.; Hurley, M. D.; Wallington, T. J.; Singh, R. Atmospheric chemistry of *trans*-CF₃CH=CHF: Kinetics of the gas-phase reactions with Cl atoms, OH radicals, and O₃. *Chem. Phys. Lett.* **2007**, *443*, 199-204, doi:10.1016/j.cplett.2007.06.084.

E40. OH + (E)-CHF=CFCF₃. The recommended value for k(298 K) is an average of the two relative rate determinations by Hurley et al.,¹ recalculated using the current recommendations for the rate constants of the reference reactions OH + C₂H₄ and OH + C₂H₂. The value for E/R is estimated from that for similar fluorinated propenes. Based on the results obtained for other fluorinated alkenes, the recommended rate constant represents the high-pressure limit for this reaction.

(Table: 10-6, Note: 10-6, Evaluated: 10-6) [Back to Table](#)

- (1) Hurley, M. D.; Ball, J. C.; Wallington, T. J. Atmospheric chemistry of the Z and E isomers of CF₃CF=CHF; Kinetics, mechanisms, and products of gas-phase reactions with Cl atoms, OH radicals, and O₃. *J. Phys. Chem. A* **2007**, *111*, 9789-9795, doi:10.1021/jp0753530.

E41. OH + (Z)-CHF=CFCF₃. The recommended value for k(298 K) is from Papadimitriou et al.² who found the rate constant to be pressure independent between 25 and 600 Torr, indicating that the high-pressure limit is achieved for this reaction. The two room temperature values from the relative rate studies by Hurley et al.¹ are in very good agreement with this recommendation. Papadimitriou et al.² found weak curvature in the Arrhenius plot from 206 K to 380 K. Thus, the recommended value for E/R is derived from a fit to their data at T ≤ 300 K. The data over the temperature range from 206 K to 380 K can be represented by the three-parameter expression obtained from the fit to the data reported by Papadimitriou et al.

$$k(T) = 1.55 \times 10^{-13} (T/298)^{1.92} \exp(+633/T).$$

(Table: 10-6, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

- (1) Hurley, M. D.; Ball, J. C.; Wallington, T. J. Atmospheric chemistry of the Z and E isomers of CF₃CF=CHF; Kinetics, mechanisms, and products of gas-phase reactions with Cl atoms, OH radicals, and O₃. *J. Phys. Chem. A* **2007**, *111*, 9789-9795, doi:10.1021/jp0753530.
- (2) Papadimitriou, V. C.; Talukdar, R. K.; Portmann, R. W.; Ravishankara, A. R.; Burkholder, J. B. CF₃CF=CH₂ and (Z)-CF₃CF=CHF: temperature dependent OH rate coefficients and global warming potentials. *Phys. Chem. Chem. Phys.* **2008**, *10*, 808-820, doi:10.1039/b714382f.

E42. OH + CF₂=CFCF₃. The recommended value for k(298 K) is an average of the values reported in the absolute rate constant investigations by McIlroy and Tully,³ Orkin et al.,⁴ Orkin et al.,⁵ and Tokuhashi et al.⁶ (two studies) and in the relative rate study by Mashino et al.² (using two different reference gases). All of these individual k(298 K) values are in excellent agreement and lie within 3% of the recommended value. Results of the room temperature relative rate study by Acerboni et al.¹ are internally inconsistent and exceed the recommended value by ~12% and ~60% when C₂H₄ and C₃H₆, respectively, were used as reference compounds. Although the first value overlaps the recommended k(298 K) within the reported uncertainty, the reason for the large difference when C₃H₆ was used as the reference compound is not clear, especially since the result for OH + C₂F₄ reported by the same group using the same reference reaction is in good agreement with other available data. The recommended value for E/R is derived from a fit of the data of Orkin et al.⁵ at T ≤ 300 K. Based on results obtained for other fluorinated alkenes, the recommended rate constant represents the high-pressure limit for this reaction. The complete data set of Orkin et al.⁵ between 230–480 K exhibits pronounced curvature in the Arrhenius plot and can be best fit by the three-parameter expression:

$$k(T) = 9.75 \times 10^{-14} (T/298)^{1.94} \exp(+922/T)$$

This expression encompasses all data from the studies used in deriving the recommendation within an f(T) factor of 1.05 between 230 K to 480 K.

E43. OH + CF₂=CFCF=CF₂. Only two relative rate studies of this reaction near room temperature have been conducted. There is approximately a 25-30% difference between the results from these studies using different reference compounds and approximately the same difference between the results when the same reference compound, C₂H₄, was used. Thus, the recommended value for k(298 K) is an average of all values determined in the relative rate studies of Acerboni et al.¹ (using ethene, propene, and cyclohexane as reference compounds) and of Wallington and Hurley² (using ethene and acetylene as reference compounds). The current recommendations for the rate constants of the reactions of OH with reference compounds were used to recalculate the results of each of the relative rate measurements. The recommended value for E/R is estimated as being approximately the same as that for OH + CF₂=CF₂.

E44. OH + CH₂=CHCF₂CF₃. The recommended value for k(298 K) is an average of the two relative rate study results by Sulbaek Andersen et al.,¹ which were recalculated using the current rate constant recommendations for the reference reactions OH + C₂H₄ and OH + C₂H₂. The recommended value for E/R is estimated as being the same as that for OH + CH₂=CHCF₃. Sulbaek Andersen et al. determined the rate constants at T = 296 K for OH reactions with CH₂=CHC_xF_{2x+1} (for x=1,2,4,6,8), and the recommendation given here covers all of these compounds. Based on results obtained for other fluorinated alkenes, the recommended rate constant represents the high-pressure limit for this reaction.

A: Chem.* **2005**, *176*, 124-128, doi:10.1016/j.jphotochem.2005.06.015.

E45. OH + (Z)-CF₃CH=CHCF₃. The recommended values for both k(298 K) and E/R are derived from a fit to the data below 300 K of Baasandorj et al.¹ The complete data set of Baasandorj et al. between 212–374 K exhibits pronounced curvature in the Arrhenius plot and can be best fit by the three-parameter expression:

$$k(T) = 3.68 \times 10^{-14} (T/298)^{2.33} \exp(+774/T)$$

(Table: 15-10, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

- (1) Baasandorj, M.; Ravishankara, A. R.; Burkholder, J. B. Atmospheric chemistry of (Z)-CF₃CH=CHCF₃: OH radical reaction rate coefficient and global warming potential. *J. Phys. Chem. A* **2011**, *115*, 10539-10549, doi:10.1021/jp206195g.

E46. OH + (E)-CF₃CF=CFCF₃. The data reported by Orkin et al.² for this individual isomer exhibit curvature in the Arrhenius plot. The recommended values for both k(298 K) and E/R are derived from a fit to the data of Orkin et al.² at T < 300 K, the only temperature range where these recommended Arrhenius parameters should be used. The data over the broader temperature range from 230 K to 370 K can be represented by the three-parameter expression obtained from the fit to the data reported by Orkin et al.²

$$k(T) = 7.5 \times 10^{-14} (T/298)^{1.68} \exp(+612/T)$$

Cometto et al.¹ and Young et al.³ studied the reaction of OH with the industrial mixture of the two isomers, (E)-octafluoro-2-butene and (Z)-octafluoro-2-butene, at room temperature using a relative rate technique. They reported rate constants that are 35% and 25% lower than the recommended value, respectively, without including uncertainties in the reference rate constants. Orkin et al.² separated and analyzed the individual isomer abundance to find that the industrial mixture contains ~71% of the more reactive (E)-octafluoro-2-

butene and ~29% of the less reactive (*Z*)-octafluoro-2-butene. Therefore, the result reported by Young et al. is in quantitative agreement with that calculated for such a mixture using the individual isomer rate constants of Orkin et al.² The result reported by Cometto et al. appears too low for such a mixture based on the values recommended here.

(Table: 15-10, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

Environ.* **2009**, *43*, 3717-3724, doi:10.1016/j.atmosenv.2009.04.025.

E47. OH + (*Z*)-CF₃CF=CFCF₃. The data reported by Orkin et al.² for this individual isomer exhibit a weak temperature dependence and curvature in the Arrhenius plot. The recommended values for both *k*(298 K) and *E*/*R* are derived from a fit to the data of Orkin et al.² at *T* < 300 K, the only temperature range where these recommended Arrhenius parameters should be used. The data over the broader temperature range from 230 K to 370 K can be represented by the three-parameter expression obtained from the fit to the data reported by Orkin et al.

$$k(T) = 3.0 \times 10^{-14} (T/298)^{2.61} \exp(+760/T)$$

Cometto et al.¹ and Young et al.³ studied the reaction of OH with the industrial mixture of the two isomers, (*E*)-octafluoro-2-butene and (*Z*)-octafluoro-2-butene, at room temperature using a relative rate technique. Orkin et al.² separated and analyzed the individual isomer abundance to find that the industrial mixture contains ~29% of the less reactive (*Z*)-octafluoro-2-butene and ~71% of the more reactive (*E*)-octafluoro-2-butene. The rate constant reported by Young et al. agrees with that calculated for such a mixture using the individual isomer rate constants measured by Orkin et al. within the total combined uncertainty. The result reported by Cometto et al. appears too low for such a mixture based on the values recommended here.

Environ.* **2009**, *43*, 3717-3724, doi:10.1016/j.atmosenv.2009.04.025.

E48. OH + (CF₃)₂C=CFCF₂CF₃. The rate constant reported by Orkin et al.² decreases with decreasing temperature and exhibits pronounced curvature in the Arrhenius plot between 250 K and 370 K. The recommended values for both *k*(298 K) and *E*/*R* are derived from a fit to the data of Orkin et al. between ~300 K and 250 K, the temperature region where the rate constant reached a minimum and became essentially temperature independent. The data over the complete temperature range from 370 K to 250 K can be represented by the three-parameter expression reported by Orkin et al.

$$k(T) = 2.17 \times 10^{-15} (T/298)^{3.90} \exp(+1044/T)$$

The uncertainty parameters were chosen to encompass the possible increase of the rate constant at lower temperatures (below 250 K) following this three-parameter expression. Jubb et al.¹ measured the rate constant ratio for CH₃OC₇F₁₃ to both (CF₃)₂C=CFCF₂CF₃ and (*Z*)-CF₃CH=CHCF₃ at 298 K, thereby enabling calculation of a room temperature rate constant for (CF₃)₂C=CFCF₂CF₃ from the current *k*(298 K) recommendation for (*Z*)-CF₃CH=CHCF₃. The resulting value is in excellent agreement with that recommended here.

E49. OH + CF₃OH. There are no measurements of the rate coefficient of this reaction. The recommendation is based on the recommended limit for the reverse reaction rate coefficient and an estimated equilibrium constant. The thermochemistry of CF₃O and CF₃OH are taken from *ab initio* calculations (Montgomery et al.² and Schneider and Wallington³) and laboratory measurements (Huey et al.¹) to estimate $\Delta G^\circ_{298}(\text{OH} + \text{CF}_3\text{OH} \rightarrow \text{CF}_3\text{O} + \text{H}_2\text{O})$ to be about (2 ± 4) kcal mol⁻¹. In considering the large uncertainty in the free energy change, the estimated rate coefficient limit is based on the assumption that the reaction is approximately thermoneutral.

E50. OH + CH₂FCH₂OH. The recommended values for $k(298 \text{ K})$ and E/R are averages of the parameters derived from fits to the data of Rajakumar et al.² and Orkin et al.¹ for $T < 300 \text{ K}$ with the former data corrected for an apparent error in the UV absorption cross section of CH₂FCH₂OH (which was used to determine the reactant concentration). When this correction is made, the data from these two studies are indistinguishable. The room temperature rate constant determined in the relative rate study of Sellevag et al.³ is about 50% greater than that recommended. The data over the temperature range 230 K to 370 K from both Rajakumar et al.² and Orkin et al.¹ exhibit curvature in the Arrhenius plot (more evident in the higher precision data from the latter study) and can be represented by the three-parameter expression reported by Orkin et al.

$$k(T) = 3.47 \times 10^{-14} (T/298)^{4.5} \exp(+977/T)$$

(Table: 15-10, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

Environ.* **2004**, *38*, 6725-6735, doi:10.1016/j.atmosenv.2004.09.023.

E51. OH + CHF₂CH₂OH. The recommended value of $k(298 \text{ K})$ is an average of the values reported in the absolute rate studies of Kovacs et al.¹ and Orkin et al.² The value of E/R is derived from a fit at $T \leq 300 \text{ K}$ to the data of Orkin et al.,² which are the only temperature dependent data available. The room temperature rate constant determined in the relative rate study of Sellevag et al.³ is about 80% greater than that recommended. The data over the temperature range from 220 K to 370 K exhibit a curvature in the Arrhenius plot and can be represented by the three-parameter expression that is derived from a fit to the data of Orkin et al.² over the temperature range from 220 K to 370 K after the data were scaled to match the recommended value of $k(298 \text{ K})$.

$$k(T) = 3.73 \times 10^{-14} (T/298)^{4.25} \exp(+578/T)$$

Environ.* **2004**, *38*, 6725-6735, doi:10.1016/j.atmosenv.2004.09.023.

E52. OH + CF₃CH₂OH. The recommended value for k(298 K) is an average of the values reported in the absolute rate studies of Wallington et al.,⁶ Tokuhashi et al.⁵ (two determinations), Kovacs et al.,² and Orkin et al.,³ and the relative rate study of Hurley et al.¹ (using OH + C₂H₂ as the reference reaction). The value of k(298 K) reported by Sellevåg et al.⁴ is significantly larger than those from all of the other studies and was not used in deriving the recommended value. The recommended value for E/R is an average of the values derived from fits to the data below 300 K of Tokuhashi et al.⁵ and Orkin et al.³ The data over the temperature range from 220 K to 370 K exhibit a curvature in the Arrhenius plot and can be represented by the three-parameter expression derived from a fit to the data of Orkin et al.³ after the data were scaled to match the recommended k(298 K).

$$k(T) = 2.57 \times 10^{-14} (T/298)^{4.0} \exp(+405/T)$$

(Table: 15-10, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

E53. OH + CF₃CF₂CH₂OH. The recommended value for k(298 K) is an average of the values derived from the data of Tokuhashi et al.³ (discharge flow and pulsed photolysis absolute rate studies) and from the relative rate studies of Chen et al.¹ (recalculated based on the current recommendation for the rate constant for the OH + CH₂Cl₂ reference reaction) and Hurley et al.² (recalculated based on the current recommendation for the rate constant for the OH + C₂H₂ reaction). The recommended value for E/R is derived from the combined fit to the temperature dependent data of Tokuhashi et al.³ (T < 400 K) and Chen et al.¹ after scaling each data set to the recommended value of k(298 K).

(Table: 10-6, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

- (1) Chen, L.; Fukuda, F.; Takenaka, N.; Bandow, H.; Maeda, Y. Kinetics of the gas-phase reaction of CF₃CF₂CH₂OH with OH radicals and its atmospheric lifetime. *Int. J. Chem. Kinet.* **2000**, *25*, 73-78.

- (3) Tokuhashi, K.; Nagai, H.; Takahashi, A.; Kaise, M.; Kondo, S.; Sekiya, A.; Takahashi, M.; Gotoh, Y.; Suga, A. Measurement of the OH reaction rate constants for CF₃CH₂OH, CF₃CF₂CH₂OH, and CF₃CH(OH)CF₃. *J. Phys. Chem. A* **1999**, *103*, 2664-2672.

E54. OH + (CF₃)₂CHOH. The results of the absolute measurements reported by Tokuhashi et al.² (three determinations) and Orkin et al.¹ are in excellent agreement over the common temperature range of the measurements. The recommended $k(298\text{ K})$ is the same value obtained in both studies. The data from Orkin et al.¹ exhibit a noticeable curvature in the Arrhenius plot between 220 K and 370 K, which is most pronounced at lower temperatures. Because of this curvature, the recommended value for E/R is derived from a fit to the data from both studies only between 298 K and 250 K. The data over the temperature range from 220 K to 370 K can be represented by the three-parameter expression that is derived from a fit to the data of Orkin et al.¹

$$k(T) = 5.7 \times 10^{-16} (T/298)^{6.65} \exp(+1125/T)$$

The g -factor is set to encompass the low temperature extrapolation of both the recommended two-parameter Arrhenius expression and the three-parameter expression from Orkin et al.¹

(Table: 15-10, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

E55. OH + CF₃CHF₂CH₂OH. The recommended value of $k(298\text{ K})$ is an average of the values derived from the two relative rate studies of Chen et al.¹ (recalculated using the recommended rate constants for the reference reactions) and the two absolute rate studies of Chen et al.¹ The recommended value for E/R is derived from a fit to all of the data (for $T < \sim 300\text{ K}$) from both the relative rate and absolute rate determinations after scaling each data set to the recommended $k(298\text{ K})$.

(Table: 15-10, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

E56. OH + CF₃CF₂CF₂CH₂OH. The recommended value for $k(298\text{ K})$ is from the relative rate study of Hurley et al.¹ (recalculated using the current recommendation for the rate constant of the OH + C₂H₂ reference reaction). The recommended value for E/R is estimated as being the same as that for the reaction of OH with CF₃CF₂CH₂OH.

(Table: 10-6, Note: 10-6, Evaluated: 10-6) [Back to Table](#)

- (1) Hurley, M. D.; Wallington, T. J.; Sulbaek Andersen, M. P.; Ellis, D. A.; Martin, J. W.; Mabury, S. A. Atmospheric chemistry of fluorinated alcohols: Reaction with Cl atoms and OH radicals and atmospheric lifetimes. *J. Phys. Chem. A* **2004**, *108*, 1973, doi:10.1021/jp0373088.

E57. OH + CH₃OCHF₂ (HFE-152a). The recommended Arrhenius parameters are derived from a fit to the data of Orkin et al.¹

(Table: 15-10, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

- (1) Orkin, V. L.; Khamaganov, V. G.; Guschin, A. G. Chem. A* **2014**, *118*, 10770-10777, doi:10.1021/jp506377w.

E58. OH + CH₃OCF₃ (HFE-143a). The recommended value for $k(298\text{ K})$ is an average of the values derived in the studies of Orkin et al.,³ Hsu and DeMore² (two relative rate determinations that have been recalculated based on the current recommendations for the rate constants of the OH + CH₃CHF₂ and OH + CH₂F₂ reference reactions), and Chen et al.¹ (two relative rate determinations that have been recalculated based on the current recommendations for the rate constants of the OH + CH₄ and OH + CH₃CCl₃ reference reactions). The recalculation procedure for relative rate measurements referenced to the OH + CH₃CHF₂ reaction is discussed in the note for that reaction. The room temperature result of Zhang et al.⁴ was not used in the derivation since it is significantly higher than the values of the other studies and was likely influenced by the presence of reactive impurities. The recommended value for E/R is derived from a fit to the data from Orkin

et al.,³ Hsu and DeMore,² and Chen et al.¹ (for T < 400 K) after scaling each data set to the recommended k(298 K).

E59. OH + CHF₂OCHF₂ (HFE-134). The recommended value of k(298 K) is an average of the values derived in the relative rate studies of Hsu and DeMore² (recalculated using the current recommendation for the rate constant of the OH + CH₃CCl₃ reference reaction) and of Wilson et al.⁴ (recalculated using the current recommendation for the rate constant of the OH + CHF₂CF₃ reference reaction) and the absolute rate study of Orkin et al.³ The recommended value for E/R is derived from a combined fit to the data from these three studies after scaling each data set to the recommended value of k(298 K). The more scattered data of Garland et al.¹ were not used in derivation of the recommended value.

E60. OH + CHF₂OCF₃ (HFE-125). The recommended Arrhenius parameters are based on results of the relative rate study of Hsu and DeMore¹ (recalculated using the current recommendation for the rate constant of the OH + CHF₃ reference reaction). Additional measurements by Hsu and DeMore¹ relative to OH + CHF₂CF₃ and OH + CH₄ are encompassed well within the 2σ uncertainty limits, but were not used for assigning the recommended rate expression due to the large differences in reactivity between the two reference species and the target molecule. The room temperature result of Zhang et al.² lies significantly higher than the recommended value, possibly due to the presence of reactive impurities in the sample.

E61. OH + CH₃OCHFCF₃. The recommended value for k(298 K) is an average of values derived from two relative rate determinations by Chen et al.¹ (recalculated using the current recommendations for the rate constants of the reference reactions OH + C₂H₆ and OH + CH₃CHF₂). The recommended E/R is derived from a fit to these data after scaling each individual data set to the recommended k(298 K).

E62. OH + $\text{CH}_2\text{FOCH}(\text{CF}_3)_2$ (Sevoflurane). The recommended value for $k(298\text{K})$ is an average of the values from the two studies (one relative rate and one absolute) by Sulbaek Andersen et al.³ The room temperature rate constants determined by Brown et al.¹ are approximately a factor of two higher than recommended here and may be indicative of impurity effects. The room temperature rate constant determined by Langbein et al.² is approximately 30% lower than recommended and is encompassed within the 95% confidence limits. The recommended value for E/R is derived from an Arrhenius fit to the data from the absolute rate constant measurements of Sulbaek Andersen et al.³

A* **2012**, *116*, 5806-5820, doi:10.1021/jp2077598.

E63. OH + $\text{CH}_3\text{OCF}_2\text{CHF}_2$. The recommended value for $k(298\text{ K})$ is an average of the values from the two absolute determinations by Tokuhashi et al.² using pulsed photolysis and discharge flow techniques. The recommended value for E/R is derived from a fit to the pulsed photolysis data below 400 K. A room temperature measurement by Heathfield et al.¹ is nearly an order of magnitude higher than recommended, which may be due to reactive impurities.

Phys. Chem. A* **2000**, *104*, 1165-1170, doi:10.1021/jp991421+.

E64. OH + $\text{CH}_3\text{OCF}_2\text{CF}_3$. The recommended Arrhenius parameters are derived from a fit to the data (below 400 K) of Tokuhashi et al.¹ (three independent absolute measurement studies). The expression, as expected, is similar to those for the OH + CH_3OCF_3 and OH + $\text{CH}_3\text{OCF}_2\text{CF}_2\text{CF}_3$ reactions.

Kinet.* **1999**, *31*, 846-853.

E65. OH + $\text{CHF}_2\text{OCH}_2\text{CF}_3$ (HFE-245fa2). The recommended value of $k(298\text{ K})$ is an average of the values reported in the absolute studies of Zhang et al.³ and Orkin et al.¹ and in the relative rate study of Oyaró et al.² (recalculated using the current recommendations for the rate constants of the OH + CH_3CCl_3 and OH + $\text{CHF}_2\text{CH}_2\text{F}$ reference reactions). The recommended value of E/R is derived from a fit to the data of Orkin et al.¹

E66. OH + CHF₂OCHFCF₃ (Desflurane). The recommended value for k(298 K) is an average of the values obtained in the absolute rate studies of Langbein et al.¹ and Sulbaek Andersen et al.³ The values of the room temperature rate constant determined in the two relative rate studies of Oyaro et al.² (relative to the reactions of OH with CH₃CCl₃ and CHF₂CH₂F) are approximately 50% greater than the recommended value. The recommendation for E/R is derived from a fit to the data of Sulbaek Andersen et al., which is the only study of the temperature dependence of this reaction.

(Table: 15-10, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

- E69. OH + CH₃OCF₂CF₂CF₃.** The recommended value for k(298 K) is an average of the values reported by Tokuhashi et al.² (two absolute measurement studies) and Ninomiya et al.¹ (two relative rate determinations, which have been recalculated based on the current recommendations for the rate constants of the OH + CH₄ and OH + CH₃Cl reference reactions). The recommended value for E/R is determined from a fit to the data (below 400 K) of Tokuhashi et al. The expression, as expected, is similar to those for the OH + CH₃OCF₃ and OH + CH₃OCF₂CF₃ reactions.
(Table: 02-25, Note: 02-25, Evaluated: 02-25) [Back to Table](#)
- (1) Ninomiya, Y.; Kawasaki, M.; Guschin, A.; Molina, L. T.; Molina, M. J.; Wallington, T. J. Atmospheric chemistry of *n*-C₃F₇OCH₃: Reaction with OH radicals and Cl atoms and atmospheric fate of *n*-C₃F₇OCH₂O(•) radicals. *Environ. Sci. Technol.* **2000**, 34, 2973-2978, doi:10.1021/es991449z.
 - (2) Tokuhashi, K.; Takahashi, A.; Kaise, M.; Kondo, S.; Sekiya, A.; Yamashita, S.; Ito, H. Rate Constants for the Reactions of OH Radicals with CH₃OCF₂CF₃, CH₃OCF₂CF₂CF₃, and CH₃OCF(CF₃)₂. *Int. J. Chem. Kinet.* **1999**, 31, 846-853.
- E70. OH + CH₃OCH(CF₃)₂ (HFE-356mm1).** The recommended values for both k(298 K) and E/R are derived from a fit to the relative rate data of Chen et al.,¹ recalculated using the recommended values for the rate constants of the reference reactions.
(Table: 15-10, Note: 15-10, Evaluated: 15-10) [Back to Table](#)
- (1) Chen, L.; Kutsuna, S.; Tokuhashi, K.; Sekiya, A.; Tamai, R.; Hibino, Y. Kinetics and mechanism of (CF₃)₂CHOCH₃ reaction with OH radicals in an environmental reaction chamber. *J. Phys. Chem. A* **2005**, 109, 4766-4771, doi:10.1021/jp050491f.
- E71. OH + CH₃OCF(CF₃)₂.** The recommendation for k(298 K) is an average of the values from the absolute measurements of Tokuhashi et al.² (three determinations) and Andersen et al.¹ The recommended value for E/R is derived from a fit to the temperature-dependent data of Tokuhashi et al.² below 400 K. The uncertainties, which were originally set to encompass the recommendations for the similar OH + CH₃OCF₃ and OH + CH₃OCF₂CF₃ reactions have been reduced slightly to account for the additional data point at 298 K.
(Table: 15-10, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

 - (2) Tokuhashi, K.; Takahashi, A.; Kaise, M.; Kondo, S.; Sekiya, A.; Yamashita, S.; Ito, H. Rate Constants for the Reactions of OH Radicals with CH₃OCF₂CF₃, CH₃OCF₂CF₂CF₃, and CH₃OCF(CF₃)₂. *Int. J. Chem. Kinet.* **1999**, 31, 846-853.
- E72. OH + CH₃OC₄F₉.** The recommendation for k(298 K) is based on the relative rate measurements by Wallington et al.² (recalculated using the current recommendation for the rate constant of the OH + CH₃Cl reference reaction). Measurements in the same study using OH + CH₄ as the reference reaction are in general agreement, but exhibit more scatter. The recommended value of k(298 K) is consistent with similar reactions of OH with CH₃OCF₃, CH₃OC₂F₅, and CH₃OC₃F₇. A relative rate study by Cavalli et al.¹ at 298 K yielded a rate constant about 60% lower than recommended. The recommended value for E/R is estimated to be approximately equal to that for the reactions of OH with CH₃OC₂F₅ and CH₃OC₃F₇.

E79. OH + $\text{CHF}_2\text{OCF}_2\text{OCHF}_2$. The recommended value for $k(298\text{ K})$ is from the relative rate study by Cavalli et al.,¹ recalculated using the current recommendation for the rate constant of the reference reaction $\text{OH} + \text{CH}_4$. The value for $k(298\text{ K})$ is identical to that for $\text{OH} + \text{CHF}_2\text{OCHF}_2$, which might be expected to have a slightly higher rate constant. The value for E/R is estimated as being similar to that for the reaction of OH with $\text{CHF}_2\text{OCHF}_2$.

(Table: 10-6, Note: 10-6, Evaluated: 10-6) [Back to Table](#)

- (1) Cavalli, F.; Glasius, M.; Hjorth, J.; Rindone, B.; Jensen, N. R. Atmospheric lifetimes, infrared spectra and degradation products of a series of hydrofluoroethers. *Atmos. Environ.* **1998**, *32*, 3767-3773.

E80. OH + $\text{CHF}_2\text{OCF}_2\text{CF}_2\text{OCHF}_2$. The recommended value for $k(298\text{ K})$ is from the relative rate study by Cavalli et al.,¹ recalculated using the current recommendation for the rate constant of the reference reaction $\text{OH} + \text{CH}_4$. However, the value for $k(298\text{ K})$ is a factor of two greater than that measured in the same study for $\text{OH} + \text{CHF}_2\text{OCF}_2\text{OCHF}_2$, which might be expected to have a similar rate constant. Hence, the recommended value for $f(298\text{ K})$ was chosen to encompass the rate constant recommended for the reaction of OH with $\text{CHF}_2\text{OCF}_2\text{OCHF}_2$. As with $\text{OH} + \text{CHF}_2\text{OCF}_2\text{OCHF}_2$, the value for E/R is estimated as being similar to that for the reaction of OH + $\text{CHF}_2\text{OCHF}_2$.

(Table: 10-6, Note: 10-6, Evaluated: 10-6) [Back to Table](#)

- (1) Cavalli, F.; Glasius, M.; Hjorth, J.; Rindone, B.; Jensen, N. R. Atmospheric lifetimes, infrared spectra and degradation products of a series of hydrofluoroethers. *Atmos. Environ.* **1998**, *32*, 3767-3773.

E81. OH + $\text{CHF}_2\text{OCF}_2\text{CF}_2\text{OCF}_2\text{OCHF}_2$. The recommended value for $k(298\text{ K})$ is from the relative rate study by Cavalli et al.,¹ recalculated using the current recommendation for the rate constant of the reference reaction $\text{OH} + \text{CH}_4$. The value for $k(298\text{ K})$ is almost the same as that measured for $\text{OH} + \text{CHF}_2\text{OCF}_2\text{CF}_2\text{OCHF}_2$ in the same study. For both compounds, the measured values for $k(298\text{ K})$ are inexplicably a factor of two greater than that measured in the same study for $\text{OH} + \text{CHF}_2\text{OCF}_2\text{OCHF}_2$, which might be expected to have the same or even slightly higher rate constant. Hence, the recommended value for $f(298\text{ K})$ was selected accordingly. As with $\text{OH} + \text{CHF}_2\text{OCF}_2\text{OCHF}_2$ and $\text{OH} + \text{CHF}_2\text{OCF}_2\text{CF}_2\text{OCHF}_2$, the value for E/R is estimated as being similar to that for the reaction of OH + $\text{CHF}_2\text{OCHF}_2$.

E82. F + O₃. The recommended parameters are based on results of the room temperature study of Bedzhanyan et al.¹ and the temperature-dependent study of Wagner et al.² The recommendation appears to be quite reasonable in view of the well-known reactivity of atomic chlorine with O₃.

(Table: 94-26, Note: 94-26, Evaluated: 94-26) [Back to Table](#)

E83. F + H₂. The value of $k(298\text{ K})$ seems to be well established with the results reported by Zhitneva and Pshezhetskii,¹⁰ Heidner et al.,^{5,6} Wurzburg and Houston,⁹ Dodonov et al.,⁴ Clyne et al.,³ Bozzelli,¹ Igoshin et al.,⁷ Clyne and Hodgson,² and Stevens et al.⁸ being in excellent agreement (range of k being $2.3\text{--}3.0 \times 10^{-11}\text{ cm}^3\text{ molecule}^{-1}\text{ s}^{-1}$). The recommended value at 298 K is taken to be the average of the values reported in these references. Values of E/R range from 433–595 K (Heidner et al.; Wurzburg and Houston; Igoshin et al.; and Stevens et al.). The recommended value of E/R is derived from a fit to the data in these studies.

E84. F + H₂O. The recommended temperature-independent value for this rate constant is based on results reported in the study by Stevens et al.² over the temperature range 240–373 K using a discharge flow system with chemical conversion of fluorine atoms to deuterium atoms and detection of the latter by resonance fluorescence. This value is in excellent agreement with the room temperature results of Frost et al.¹ and Walther and Wagner.³ In a limited temperature-dependent study, Walther and Wagner reported an E/R value of 400 K. Although these data have not been included in the derivation of the recommended value for E/R , with the exception of the one low temperature data point, they are encompassed within the indicated uncertainty limits.

E85. F + HNO₃. The recommendation is based on results of the temperature-dependent study of Wine et al.⁴ and the room temperature results of Mellouki et al.,² Rahman et al.,³ and Becker et al.¹ The rate constant values at room temperature are in good agreement. The study of Wine et al.⁴ was conducted over the temperature range 260–373 K. Below 320 K the data were fit by the Arrhenius expression recommended here, whereas at higher temperatures a temperature-independent value was found, suggesting the occurrence of different mechanisms in the two temperature regimes.

E86. $F + CH_4$. The recommended value of $k(298\text{ K})$ is the average of the results of Wagner et al.,⁶ Clyne et al.,¹ Kompa and Wanner,⁴ Foon and Reid,³ Fasano and Nogar,² and Persky et al.⁵ The temperature dependence is that reported by Persky et al. in a competitive study using $F + D_2$ as the reference reaction. These results are recommended over the temperature dependences reported in the earlier studies of Wagner et al. and Foon and Reid.

- (6) Wagner, H. G.; Warnatz, J.; Zetzsch, C. On the reaction of F atoms with methane. *Anales Assoc. Quim. Argentina* **1971**, 59, 169-177.

E87. $FO + O_3$. The recommended upper limit for $k(298\text{ K})$ is based on the results of Li et al.² in a study using a discharge flow-mass spectrometric technique. FO was produced in the reaction of F atoms with excess O_3 . No appreciable decay of FO, and only a small increase in FO_2 , was detected, allowing an upper limit to the rate constant of $10^{-14}\text{ cm}^3\text{ molecule}^{-1}\text{ s}^{-1}$ to be derived. A two orders of magnitude higher upper limit was derived by Sehested et al.³ A lower value of the upper limit was derived by Colussi and Grela¹ from a re-analysis of data on the quantum yields for ozone destruction in F_2/O_3 mixtures reported by Starrico et al.⁴ The results of the recent, more direct, study of Li et al.² are preferred over the earlier results of Starrico et al. There are two possible pathways which are exothermic, resulting in the production of $F + 2O_2$ or $FO_2 + O_2$. (Table: 97-4, Note: 97-4, Evaluated: 97-4) [Back to Table](#)

- E90. FO₂ + O₃.** The recommended upper limit for k(298 K) is based on results of Sehested et al.² A higher upper limit has been reported by Li et al.¹
(Table: 94-26, Note: 97-4, Evaluated: 97-4) [Back to Table](#)
- (1) Li, Z.; Friedl, R. R.; Sander, S. P. Kinetics of FO₂ with NO, NO₂, O₃, CH₄ and C₂H₆. *J. Phys. Chem.* **1995**, 99, 13445-13451, doi:10.1021/j100036a019.
 - (2) Sehested, J.; Sehested, K.; Nielsen, O. J.; Wallington, T. J. Atmospheric chemistry of FO₂ radicals: Reaction with CH₄, O₃, NO, NO₂, and CO at 295 K. *J. Phys. Chem.* **1994**, 98, 6731-6739, doi:10.1021/j100078a014.
- E91. FO₂ + NO.** The recommended parameters are based on results of Li et al.,¹ the only temperature-dependent study. The recommended value for k(298 K) is nearly a factor of 2 less than that reported by Sehested et al.²
(Table: 97-4, Note: 97-4, Evaluated: 97-4) [Back to Table](#)
- (1) Li, Z.; Friedl, R. R.; Sander, S. P. Kinetics of FO₂ with NO, NO₂, O₃, CH₄ and C₂H₆. *J. Phys. Chem.* **1995**, 99, 13445-13451, doi:10.1021/j100036a019.
 - (2) Sehested, J.; Sehested, K.; Nielsen, O. J.; Wallington, T. J. Atmospheric chemistry of FO₂ radicals: Reaction with CH₄, O₃, NO, NO₂, and CO at 295 K. *J. Phys. Chem.* **1994**, 98, 6731-6739, doi:10.1021/j100078a014.
- E92. FO₂ + NO₂.** The recommended parameters are based on the results of Li et al.,¹ the only temperature-dependent study. The recommended value for k(298 K) is a factor of 2.5 less than the results of Sehested et al.² This discrepancy might be attributable to a small NO impurity in the NO₂ sample used in the Sehested et al. study.
(Table: 97-4, Note: 97-4, Evaluated: 97-4) [Back to Table](#)
- (1) Li, Z.; Friedl, R. R.; Sander, S. P. Kinetics of FO₂ with NO, NO₂, O₃, CH₄ and C₂H₆. *J. Phys. Chem.* **1995**, 99, 13445-13451, doi:10.1021/j100036a019.

- E93. FO₂ + CO.** The recommended upper limit for k(298 K) is based on results of Sehested et al.,¹ the only published study of this reaction.
(Table: 94-26, Note: 94-26, Evaluated: 94-26) [Back to Table](#)
- (1) Sehested, J.; Sehested, K.; Nielsen, O. J.; Wallington, T. J. Atmospheric chemistry of FO₂ radicals: Reaction with CH₄, O₃, NO, NO₂, and CO at 295 K. *J. Phys. Chem.* **1994**, 98, 6731-6739, doi:10.1021/j100078a014.
- E94. FO₂ + CH₄.** The recommended upper limit for k(298 K) is based on results of Li et al.¹ This upper limit is a factor of 20 less than derived in the study by Sehested et al.²
(Table: 97-4, Note: 97-4, Evaluated: 97-4) [Back to Table](#)
- (1) Li, Z.; Friedl, R. R.; Sander, S. P. Kinetics of FO₂ with NO, NO₂, O₃, CH₄ and C₂H₆. *J. Phys. Chem.* **1995**, 99, 13445-13451, doi:10.1021/j100036a019.

- (2) Sehested, J.; Sehested, K.; Nielsen, O. J.; Wallington, T. J. Atmospheric chemistry of FO₂ radicals: Reaction with CH₄, O₃, NO, NO₂, and CO at 295 K. *J. Phys. Chem.* **1994**, *98*, 6731-6739, doi:10.1021/j100078a014.
- E95. CF₃O + O₂.** The recommendation is based upon the results of Turnipseed et al.¹ who reported $k(373\text{ K}) \leq 4 \times 10^{-17} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$. Assuming an E/R of 5000 K, which is equal to the reaction endothermicity, yields the recommended A and $k(298\text{ K})$ limits. By comparison to other reactions involving abstraction by O₂, the A- factor is likely to be much smaller.
(Table: 94-26, Note: 94-26, Evaluated: 94-26) [Back to Table](#)
- (1) Turnipseed, A. A.; Barone, S. B.; Ravishankara, A. R. Kinetics of the reactions of CF₃O_x radicals with NO, O₃, and O₂. *J. Phys. Chem.* **1994**, *98*, 4594-4601.
- E96. CF₃O + O₃.** The recommended value for $k(298\text{ K})$ is based on the average of room temperature measurements reported by Turnipseed et al.,⁶ Wallington and Ball,⁷ and Bourbon et al.¹ Turnipseed et al. and Bourbon et al. made direct measurements using LIF detection of CF₃O with pulsed photolysis and flow tube reactors, respectively. Wallington and Ball used a competitive reaction scheme with IR absorption detection and CF₃O + CH₄ as the reference reaction. The recommended A factor is estimated by comparison to other CF₃O reactions, and the E/R is calculated to agree with the recommended $k(298\text{ K})$. Upper limits reported by Maricq and Szente,³ Nielsen and Sehested,⁵ and Wallington et al.⁸ are consistent with the $k(298\text{ K})$ recommendation. Measurements reported by Fockenberg et al.² and Meller and Moortgat⁴ give rate coefficients about an order of magnitude less than the recommended value. Although the reason for this discrepancy is not known, both studies may have possibly been affected by significant secondary chemistry. The reaction products have not been observed.

- E97. CF₃O + H₂O.** The recommendation is based upon the measurement of $k(381\text{ K}) \leq 2 \times 10^{-16} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ reported by Turnipseed et al.¹ As for the reaction CF₃O + O₃, the A factor is estimated, and the E/R is calculated to fit $k(381\text{ K})$. The limits $k = (0.2-40) \times 10^{-17} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ at $296 \pm 2\text{ K}$ given by Wallington et al.² are consistent with the recommendation.

- E98. CF₃O + NO.** The recommended value for $k(298\text{ K})$ is based upon the room temperature rate coefficients reported by Sehested and Nielsen,⁷ Turnipseed et al.,⁸ and Jensen et al.,⁶ which are in very good agreement. An earlier low value given by Bevilacqua et al.¹ is superseded by Jensen et al. The temperature-dependence is derived from measurements by Turnipseed (233–360 K) and Jensen et al. (231–393 K). The room temperature results from Bourbon et al.³ and Bhatnagar and Carr² and the results from the temperature

dependence study by Dibble et al.⁵ are in good agreement with the recommendation. The reaction products have been reported by Chen et al.,⁴ Bevilacqua et al.,¹ Bhatnagar and Carr,² and Dibble et al.⁵ (Table: 94-26, Note: 97-4, Evaluated: 97-4) [Back to Table](#)

- (7) Sehested, J.; Nielsen, O. J. Absolute rate constants for the reaction of CF_3O_2 and CF_3O radicals with NO at 295 K. *Chem. Phys. Lett.* **1993**, 206, 369-375.
- (8) Turnipseed, A. A.; Barone, S. B.; Ravishankara, A. R. Kinetics of the reactions of CF_3O_x radicals with NO , O_3 , and O_2 . *J. Phys. Chem.* **1994**, 98, 4594-4601.

E99. $\text{CF}_3\text{O} + \text{NO}_2$. There are no published measurements of the rate coefficient for this reaction. The reaction products have been reported by Chen et al.,¹ who used photolysis of CF_3NO to prepare CF_3O_2 and subsequently CF_3O in 700 Torr of air at 297 ± 2 K. They considered two product channels: (a) CF_3ONO_2 obtained via three-body recombination and (b) $\text{CF}_2\text{O} + \text{FNO}_2$ obtained via fluorine transfer. Products from both channels were observed and found to be thermally stable in their reactor. They report $k_a/(k_a + k_b) \geq 90\%$ and $k_b/(k_a + k_b) \leq 10\%$, thus the formation of CF_3ONO_2 is the dominant channel at 700 Torr and 297 K. (Table: 94-26, Note: 94-26, Evaluated: 94-26) [Back to Table](#)

- (1) Chen, J.; Young, V.; Zhu, T.; Niki, H. Long path Fourier transform infrared spectroscopic study of the reactions of CF_3OO and CF_3O radicals with NO_2 . *J. Phys. Chem.* **1993**, 97, 11696-11698.

E100. $\text{CF}_3\text{O} + \text{CO}$. The kinetics of this reaction were studied by Turnipseed et al.,¹ who used pulsed laser photolysis with pulsed laser-induced fluorescence detection and a flow tube reactor with chemical ionization detection to obtain data at temperatures from 233 to 332 K and at pressures from 0.8 to about 300 Torr in He and at about 300 Torr in SF_6 . The reaction was found to be predominantly a three-body recombination, presumably producing CF_3OCO , as described in Table 2-1. The bimolecular reaction has at least two product channels: (a) $\text{CF}_2\text{O} + \text{CFO}$ and (b) $\text{CF}_3 + \text{CO}_2$. The recommended upper limit for the bimolecular rate coefficient is derived from the low pressure results of Turnipseed et al., where the reaction was in the fall-off region. Their low pressure data indicate that $k_b < 4 \times 10^{-16} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ at 298 K. The fate of the CF_3OCO adduct is uncertain, and it may lead to the regeneration of CF_3 or CF_3O radicals in the atmosphere. Wallington and Ball² report a yield of $96 \pm 8\%$ CO_2 at one atmosphere and 296 ± 2 K. (Table: 94-26, Note: 97-4, Evaluated: 97-4) [Back to Table](#)

- (1) Turnipseed, A. A.; Barone, S. B.; Jensen, N. R.; Hanson, D. R.; Howard, C. J.; Ravishankara, A. R. Kinetics of the reactions of CF_3O radicals with CO and H_2O . *J. Phys. Chem.* **1995**, 99, 6000-6009.

E101. $\text{CF}_3\text{O} + \text{CH}_4$. The recommended value of $k(298 \text{ K})$ is an average of the values reported in the absolute studies of Saathoff and Zellner,⁸ Barone et al.,¹ Jensen et al.,⁶ Bourbon et al.,⁴ and Bednarek et al.,² which are all in excellent agreement. Kelly et al.⁷ used a relative method with FTIR detection to determine the ratio $k(\text{CF}_3\text{O} + \text{CH}_4)/k(\text{CF}_3\text{O} + \text{C}_2\text{H}_6) = R = 0.01 \pm 0.001$ at 298 ± 2 K. This ratio is considerably smaller than that calculated from the rate constants recommended in this evaluation, which is $R = 0.017$. However, a relative rate measurement reported by Wallington and Ball⁹ yields $R = 0.0152 \pm 0.0023$ at 296 K, which is in good agreement with that calculated from the recommended rate coefficients. A relative rate measurement reported by Chen et al.⁵ using FTIR methods also gives a low result for the rate coefficient for this reaction, thus, in better agreement with the value of R from Kelly et al.⁷ The recommended temperature dependence is

from the data of Barone et al. (247–360 K), Jensen et al. (231–385 K), and Bednarek et al. (235–401 K), which agree very well. Measurements at higher temperatures by Bourbon et al. (296–573 K) yield a higher value E/R (1606 K). The CF₃OH product was observed by Jensen et al. and Bevilacqua et al.³ (Table: 97-4, Note: 97-4, Evaluated: 97-4) [Back to Table](#)

E102. CF₃O + C₂H₆. The recommended value for k(298 K) is based on results reported by Saathoff and Zellner,⁵ Barone et al.,¹ and Bourbon et al.,² which are in excellent agreement. Chen et al.³ measured the rate coefficient relative to that for the CF₃O + NO reaction in 700 Torr of air at 297 K. Their ratio is in good agreement with the values recommended in this evaluation. Kelly et al.⁴ used a relative method with FTIR detection to determine the ratio k(CF₃O + CH₄)/k(CF₃O + C₂H₆) = R = 0.01 ± 0.001 at 298 ± 2 K. This does not agree with the ratio calculated using the rate constants recommended in this evaluation, which is R = 0.017. However, a relative rate measurement reported by Wallington and Ball⁶ yields R = 0.0152 ± 0.0023 at 296 K in good agreement with that calculated using the recommended rate coefficients. The recommended temperature dependence is from the work of Barone et al., who studied the reaction over the temperature range from 233 to 360 K. Measurements by Bourbon et al. (295–573 K) give a higher E/R (642 K). The products are inferred by analogy to other reactions of CF₃O with organic compounds. (Table: 97-4, Note: 97-4, Evaluated: 97-4) [Back to Table](#)

E103. CF₃O₂ + O₃. The recommended upper limit for k(298 K) is from the measurements reported by Ravishankara et al.,⁴ who used chemical ionization detection of CF₃O₂ with a flow tube reactor. No measurable reaction was observed in their study. The less direct studies of Nielsen and Sehested,³ Maricq and Szente,¹ and Turnipseed et al.⁵ report somewhat larger upper limits to the rate coefficient. An observable reaction was reported in an indirect measurement by Meller and Moortgat.² However, their result for the CF₃O + O₃ reaction is not consistent with the value recommended in this evaluation, suggesting that their study may have interference from unknown reactions. The products are assumed to be CF₃O + 2O₂. (Table: 94-26, Note: 94-26, Evaluated: 94-26) [Back to Table](#)

E104. $\text{CF}_3\text{O}_2 + \text{CO}$. The recommended upper limit for $k(298\text{ K})$ is from Turnipseed et al.,² who used chemical ionization mass spectrometric detection of CF_3OO with a flow tube reactor at 296 K. This result is at odds with an earlier study by Czarnowski and Schumacher,¹ who deduced a "fast reaction" when they observed the thermal decomposition of $\text{CF}_3\text{OOOCF}_3$ to accelerate in the presence of CO at 315–343 K. It is possible that the reaction of CF_3O with CO could account for their observations.

E105. $\text{CF}_3\text{O}_2 + \text{NO}$. The recommended value for $k(298\text{ K})$ is an average of the room temperature rate coefficients reported by Plumb and Ryan,⁶ Dognon et al.,⁴ Peeters et al.,⁵ Bevilacqua et al.,¹ Sehested and Nielsen,⁷ Turnipseed et al.,⁸ Bourbon et al.,³ and Bhatnagar and Carr,² all of which are in excellent agreement. The temperature dependence is derived from the results of Dognon et al. Several studies have confirmed the identity of the products.

1.11 ClO_x Reactions

1.11.1 Table 1F: ClO_x Reactions

Reaction	Temperature Range of Exp. Data (K) ^a	A-Factor	E/R	k(298 K) ^b	f(298 K) ^c	g	Note
$O + ClO \rightarrow Cl + O_2$	220–1250	2.8×10^{-11}	–85	3.7×10^{-11}	1.05	50	F 1
$O + OCIO \rightarrow ClO + O_2$	243–400	2.4×10^{-12}	960	1.0×10^{-13}	2.0	300	F 2
$O + OCIO \xrightarrow{M} ClO_3$		(See Table 2-1)					
$O + Cl_2O \rightarrow ClO + ClO$	230–297	2.7×10^{-11}	530	4.5×10^{-12}	1.2	100	F 3
$O + HCl \rightarrow OH + Cl$	293–3197	1.0×10^{-11}	3300	1.5×10^{-16}	1.5	350	F 4
$O + HOCl \rightarrow OH + ClO$	213–298	1.7×10^{-13}	0	1.7×10^{-13}	3.0	300	F 5
$O + ClONO_2 \rightarrow \text{products}$	202–325	3.6×10^{-12}	840	2.1×10^{-13}	1.2	100	F 6
$O_3 + OCIO \rightarrow \text{products}$	262–298	2.1×10^{-12}	4700	3.0×10^{-19}	2.5	1000	F 7
$O_3 + Cl_2O_2 \rightarrow \text{products}$	195–217			$<1 \times 10^{-19}$			F 8
$OH + Cl_2 \rightarrow HOCl + Cl$	231–836	2.6×10^{-12}	1100	6.5×10^{-14}	1.1	200	F 9

Shaded areas indicate changes or additions since JPL10-6. Italicized [blue](#) entries denote estimates.

^a Temperature range of available experimental data. This is not necessarily the range of temperature over which the recommended Arrhenius parameters are applicable. See the corresponding note for each reaction for such information.

^b Units are cm³ molecule⁻¹ s⁻¹.

^c *f*(298 K) is the uncertainty factor at 298 K. To calculate the uncertainty at other temperatures, use the expression:

$$f(T) = f(298 \text{ K}) \exp \left| g \left(\frac{1}{T} - \frac{1}{298} \right) \right|$$

Note that the exponent is an absolute value.

1.11.2 Notes: ClO_x Reactions

F1. O + ClO. There have been six studies of this rate constant over an extended temperature range using a variety of techniques: Leu⁵; Margitan;⁶ Schwab et al.,¹⁰ Ongstad and Birks;⁹ Nicovich et al.;⁷ and Goldfarb et al.³ The recommended value is based on a least squares fit to the data reported in these studies and in the earlier studies of Zahniser and Kaufman¹¹ and Ongstad and Birks.⁸ Values reported in the early studies of Bemand et al.¹ and Clyne and Nip² are significantly higher and were not used in deriving the recommended value. Leu and Yung⁴ were unable to detect O₂(¹Δ) or O₂(¹Σ) and set upper limits to the branching ratios for their production of 4.4×10^{-4} and 2.5×10^{-2} , respectively.

F2. O + OCIO. The recommended value is based on results of the DF-RF study of Gleason et al.⁴ Over the temperature range from 400 K down to 240 K, their data are well fitted by the recommended Arrhenius expression, but at lower temperatures down to 200 K their data show an abrupt change to a negative temperature dependence. At 200 K, the value measured is a factor of 3 higher than that calculated from the Arrhenius expression. It appears that the earlier experiments of Bemand et al.¹ were complicated by secondary chemistry. The low temperature data of Gleason et al. qualitatively support the results of Colussi² and Colussi et al.³ over an extended pressure range that demonstrate the importance of the termolecular reaction O + OCIO + M → ClO₃ + M (see entry for this reaction in Table 2-1). Mauldin et al.⁵ also observed product formation at low temperatures and higher pressures that is consistent with adduct formation. It should be noted that the termolecular rate constants derived by Gleason et al. on the basis of their low temperature data are not consistent with the termolecular rate constant expression recommended in this evaluation (factor of 3 difference).

- F3. $O + Cl_2O$.** The recommended value is based on the results of Stevens and Anderson⁴ and Miziolek and Molina,³ which are in good agreement. The significantly lower values of Wecker et al.⁵ are not included, nor are earlier results by Basco and Dogra¹ and Freeman and Phillips² due to data analysis difficulties in both studies.

- F4. $O + HCl$.** The recommended value is based on the results of Brown and Smith,² Wong and Belles,⁷ Ravishankara et al.,⁵ Hack et al.,³ Singleton and Cvetanovic,⁶ and Mahmud et al.⁴ near 300 K, but not on the results reported by Balakhnin et al.,¹ which are substantially higher. A large uncertainty is attached to the temperature dependence below room temperature due to the limited number and range (no data below 290 K) of measurements.

 - (7) Wong, E. L.; Belles, F. R.; NASA TN D-6495 NASA Washington, D. C., 1971.
- F5. $O + HOCl$.** The recommended value is based on results of Schindler et al.¹ In this study the rate constant was found to be practically independent of temperature in the range 213–298 K. Product analysis indicated that Cl atom abstraction is the primary reaction channel, a conclusion that is supported by ab initio studies carried out by Xu and Lin,³ Wang et al.,² and Schindler et al.

- F6. $O + ClONO_2$.** The recommended values are based on the results reported by Goldfarb et al.,² Molina et al.,⁴ and Kurylo.³ The room temperature results of Tyndall et al.⁶ and Adler-Golden and Wiesenfeld¹ are in excellent agreement with the recommended value. The value reported by Ravishankara et al.⁵ at 245 K is a

factor of 2 greater than the results from the other studies, and this may possibly be attributed to (a) secondary kinetic complications, (b) the presence of NO₂ as a reactive impurity in the ClONO₂, or (c) formation of reactive photolytic products. Goldfarb et al. measured an essentially unit yield ($\pm$ 30%) of NO₂ from the reaction between the temperatures 248 K and 298 K.

F7. O₃ + OCIO. The recommended value is based on results over the temperature range 262–296 K reported by Wongdontri-Stuper et al.² The indicated uncertainty limits also encompass the somewhat lower room temperature result of Birks et al.¹

(Table: 90-1, Note: 90-1, Evaluated: 10-6) [Back to Table](#)

F9. OH + Cl₂. The recommended room temperature value is the average of the results reported by Bryukov et al.,² Gilles et al.,³ Boodaghians et al.,¹ Loewenstein and Anderson,⁵ Ravishankara et al.,⁶ and Leu and Lin.⁴ The temperature dependence is based on an error-weighted average of the Gilles et al. and Boodaghians et al. E/R values. Loewenstein and Anderson determined that the exclusive products are Cl + HOCl.

- (4) Leu, M.-T.; Lin, C. L. Rate constants for the reactions of OH with ClO, Cl₂, and Cl₂O at 298K. *Geophys. Res. Lett.* **1979**, 6, 425-428.
- (5) Loewenstein, L. M.; Anderson, J. G. Rate and product measurements for the reactions of OH with Cl₂, Br₂, and BrCl at 298 K. Trend interpretations. *J. Phys. Chem.* **1984**, 88, 6277-6286, doi:10.1021/j150669a045.
- (6) Ravishankara, A. R.; Eisele, F. L.; Wine, P. H. The kinetics of the reaction of OH with ClO. *J. Chem. Phys.* **1983**, 78, 1140-1144.

F10. OH + ClO. The reaction has two known product channels under atmospheric conditions: OH + ClO → Cl + HO₂ and OH + ClO → HCl + O₂. Most studies measured the rate coefficients for the overall reaction (OH +

ClO → products), which is presumably the sum of the two channels. The assessment of the overall reaction (OH + ClO → products) is based on a fit to the data of Hills and Howard³ (219–373 K), Lipson et al.⁷ (208–298 K), Kegley-Owen et al.⁴ (234–356 K), Poulet et al.⁸ (298 K), Wang and Keyser¹¹ (218–298 K), and Bedjanian et al.¹ (230–360 K). Data reported in the studies of Burrows et al.,² Ravishankara et al.,⁹ and Leu and Lin⁵ were not used in deriving the recommended value because the concentration of ClO was determined by an indirect method. The recommendation for the Cl + HO₂ channel is obtained from the equilibrium constant for this channel, combined with the recommended value for the reverse reaction. The minor reaction channel forming HCl poses significant experimental difficulties due to complications associated with the measurement of the HCl reaction product. Early studies inferred the HCl branching ratio without measuring HCl. These included the 298 K measurements of the yield of the Cl + HO₂ channel by Leu and Lin⁵ (>0.65), Burrows et al.² (0.85 ± 0.2), and Hills and Howard³ (0.86 ± 0.14). Poulet et al.⁸ measured the Cl + HO₂ product yield to be 0.98 ± 0.12 using mass spectrometry, but their HCl sensitivity was marginal. These studies were not considered in the evaluation. Later studies by Lipson et al.⁷ using mass spectrometry and by Wang and Keyser¹² using diode laser spectroscopy improved the precision of the HCl product channel measurements. Lipson et al.⁶ measured rate constants for the HCl channel over the temperature range 207–298 K and reported a branching ratio of (7 ± 3%), while Wang and Keyser¹² measured the HCl yield between 218–298 K, obtaining (9.0 ± 4.8) %, independent of temperature. The Wang and Keyser rate constant was computed from the HCl yield and their overall rate constant.¹¹ Measurements by Tyndall et al.¹⁰ and Bedjanian et al.¹ were also considered. (Although the values for the HCl channel obtained by Lipson et al. from combining the values obtained in Lipson et al.^{6,7} and Bedjanian et al.¹ are in agreement, their values for the overall reaction differ by 40–70%.) The recommendation for the HCl channel is unchanged from JPL 06-2, and the error limits have been reduced.

F11. OH + OCIO. The recommended value is that reported by Gierczak et al.¹ over the range 242–392 K. An earlier study by Poulet et al.² between 298 K and 473 K is in fair agreement with the recommendation. Differences between the studies may lie in the methods used to determine the OCIO concentration. Gierczak et al. used in situ optical measurements of OCIO, whereas Poulet et al. relied on measured flows of dilute mixtures. Product HOCl was detected in the Poulet et al. study by modulated molecular beam mass spectrometry. The branching ratio for the channel to produce HOCl + O₂ was determined to be close to unity, but experimental uncertainty would allow it to be as low as 0.80.

- (2) Poulet, G.; Zagogianni, H.; Le Bras, G. Kinetics and mechanism of the OH + ClO₂ reaction. *Int. J. Chem. Kinet.* **1986**, 18, 847-859.

F12. OH + Cl₂O. The reaction has been studied as a function of temperature by Stevens and Anderson⁴ and Hansen et al.² The results of these two studies are in excellent agreement at temperatures below 300 K. Hansen et al. suggest that data taken above 300 K by Stevens and Anderson were complicated by wall decomposition of Cl₂O. The recommended value of E/R is the average of the individual E/R values from the two studies for data below 300 K. The recommended value for k(298 K) is an average of the results from Stevens and Anderson, Hansen et al., Ennis and Birks,¹ and Leu and Lin.³

- (2) Hansen, J. C.; Friedl, R. R.; Sander, S. P. Kinetics of the OH + ClOOCl and OH + Cl₂O reactions: Experiment and theory. *J. Phys. Chem. A* **2008**, 112, 9229-9237, doi:10.1021/jp8007706.
- (3) Leu, M.-T.; Lin, C. L. Rate constants for the reactions of OH with ClO, Cl₂, and Cl₂O at 298K. *Geophys. Res. Lett.* **1979**, 6, 425-428.
- (4) Stevens, P. S.; Anderson, J. G. Kinetic and mechanistic study of X + ClOCl → products (X = Br, Cl, F, O, OH, N) over the temperature range 240-373 K. *J. Phys. Chem.* **1992**, 96, 1708-1718, doi:10.1021/j100183a040.

F13. OH + Cl₂O₂. The recommended value is based on results from the study of Hansen et al.¹ using a discharge flow technique coupled with direct detection of OH and Cl₂O₂ via resonance fluorescence and mass spectrometric techniques, respectively. Ab initio calculations by Hansen et al. support the finding of a negative temperature dependence.
(Table: 10-6, Note: 10-6, Evaluated: 10-6) [Back to Table](#)

- (1) Hansen, J. C.; Friedl, R. R.; Sander, S. P. Kinetics of the OH + ClOOCl and OH + Cl₂O reactions: Experiment and theory. *J. Phys. Chem. A* **2008**, 112, 9229-9237, doi:10.1021/jp8007706.

F14. OH + HCl. The recommended value is based on a least squares fit to the data over the temperature range 204–300 K reported in the studies of Molina et al.,⁸ Keyser,⁷ Ravishankara et al.,¹⁰ Battin-Leclerc et al.,¹ and Bryukov et al.² In these studies particular attention was paid to the determination of the absolute concentration of HCl by UV and IR spectrophotometry. Earlier studies by Takacs and Glass,¹⁵ Zahniser et al.,¹⁶ Smith and Zellner,¹³ Ravishankara et al.,⁹ Hack et al.,⁴ Husain et al.,⁵ Cannon et al.,³ Husain et al.,⁶ and Smith and Williams¹² had reported somewhat lower room temperature values. The data of Sharkey and Smith¹¹ over the temperature range 138–216 K, Battin-Leclerc et al.¹ below 240 K, and Bryukov et al. over the temperature range 298–1015 K, depart from normal Arrhenius behavior. Quantum chemical and transition state calculations performed by Battin-Leclerc et al.,¹ Bryukov et al.,² and Steckler et al.¹⁴ generally support the existence of a weakly bound complex; however, a large tunneling effect is required to explain the low temperature data. Additional work at low temperature is needed to confirm the strong non-Arrhenius behavior.

F15. OH + HOCl. In the only reported study of this system, Ennis and Birks¹ reported the value of this rate constant at room temperature to lie in the range $(1.7\text{--}9.5) \times 10^{-13} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$. A temperature-dependent expression has been estimated by choosing a pre-exponential factor by analogy with the OH + H₂O₂ reaction and selecting the midpoint of the experimental range for the room temperature rate constant. Theoretical calculations by Wang et al.,² however, suggest that tunneling may play an important role at lower temperatures and give rise to a significant curvature in the Arrhenius curve. The large uncertainty factor is needed to encompass the entire range.

(Table: 87-41, Note: 10-6, Evaluated: 10-6) [Back to Table](#)

- (1) Ennis, C. A.; Birks, J. W. Rate constants for the reactions OH + HOCl → H₂O + ClO and H + HOCl → products. *J. Phys. Chem.* **1988**, *93*, 1119-1126, doi:10.1021/j100316a024.

F16. OH + ClNO₂. The recommended value is based on results of the direct studies of Ganske et al.^{1,2} using the discharge flow-resonance fluorescence technique. Mass spectrometric studies showed HOCl to be the major chlorine-containing product, with no evidence for a channel to produce HONO₂ + Cl.

(Table: 94-26, Note: 94-26, Evaluated: 94-26) [Back to Table](#)

- (1) Ganske, J. A.; Berko, H. N.; Ezell, M. J.; Finlayson-Pitts, B. J. Kinetics of the gas-phase reaction of OH with ClNO₂ from 259 to 348 K. *J. Phys. Chem.* **1992**, *96*, 2568-2572.
- (2) Ganske, J. A.; Ezell, M. J.; Berko, H. N.; Finlayson-Pitts, B. J. The reaction of OH with ClNO₂ at 298 K: kinetics and mechanisms. *Chem. Phys. Lett.* **1991**, *179*, 204-210.

F17. OH + ClONO₂. The results reported by Zahniser et al.² and Ravishankara et al.¹ are in good agreement at ~245 K (within 25%), considering the difficulties associated with handling ClONO₂. The recommended value is that of Zahniser et al. Neither study reported data on the reaction products.

(Table: 82-57, Note: 82-57, Evaluated: 10-6) [Back to Table](#)

- (1) Ravishankara, A. R.; Davis, D. D.; Smith, G.; Tesi, G.; Spencer, J. A study of the chemical degradation of ClONO₂ in the stratosphere. *Geophys. Res. Lett.* **1977**, *4*, 7-9.

F18. OH + CH₃Cl. The recommended value for $k(298 \text{ K})$ is an average of the values from the relative rate study of Hsu and DeMore⁶ (recalculated based on the current recommendation for the rate constant of the OH +

CH₃CHF₂ reference reaction, as described in the note for that reaction) and the absolute rate studies of Herndon et al.⁴ and Orkin et al.⁸ The recommended value for E/R was obtained from a fit to the data of Herndon et al.⁴ below room temperature. Data from the earlier studies of Howard and Evenson,⁵ Perry et al.,¹⁰ Davis et al.,³ Paraskevopoulos et al.,⁹ Jeong and Kaufman⁷, and Taylor et al.¹¹ (with the exception of their 298 K data point) are reasonably well encompassed within the 2σ uncertainty limits. The room temperature value from Taylor et al.¹¹ is inconsistent with the higher temperature results in the same study and with the other investigations and lies outside of the 2σ band, as do the higher room temperature values of Cox et al.² and Brown et al.¹

- (11) Taylor, P. H.; D'Angelo, J. A.; Martin, M. C.; Kasner, J. H.; Dellinger, B. Laser photolysis/laser-induced fluorescence studies of reaction rates of OH with CH₃Cl, CH₂Cl₂, and CHCl₃ over an extended temperature range. *Int. J. Chem. Kinet.* **1989**, *21*, 829-846.

F19. OH + CH₂Cl₂. The recommended values for k(298 K) and E/R are derived from a combined fit to the data from the absolute rate studies of Villenave et al.⁹ and Herndon et al.³ and the relative rate study of Hsu and DeMore⁵ (two determinations, which have been recalculated based on the current recommendations for the rate constants of the OH + CH₃CHF₂ and OH + CH₃CH₂F reference reactions). The renormalization procedure is discussed in the note for the OH + CH₃CHF₂ reaction. The lowest temperature data (219–220 K) of Herndon et al. were not used in the fit since they appear to be systematically higher than expected from the data at 227 K and above, a difference that could possibly be due to the presence of residual reactive stabilizer in the sample of CH₂Cl₂. The results of Cox et al.¹ and Davis et al.² support the recommendation. The results from Taylor et al.,⁸ Jeong and Kaufman,⁶ Perry et al.,⁷ and Howard and Evenson⁴ lie considerably higher than the recommendation and were not used in deriving the recommended parameters.

F20. OH + CHCl_3 . The recommended value for $k(298\text{ K})$ is an average of the values from the relative rate study of Hsu and DeMore³ (which has been recalculated based on the current recommendation for the rate constant of the $\text{OH} + \text{CH}_3\text{CHF}_2$ reference reaction, as described in the note for that reaction) and the absolute rate studies of Taylor et al.⁶ (which superseded Taylor et al.⁵), Jeong and Kaufman,⁴ Davis et al.,¹ and Howard and Evenson.² The recommended value of E/R is an average of values for this parameter derived in all of the above studies with the exception of Howard and Evenson, which was conducted only at room temperature. (Table: 02-25, Note: 02-25, Evaluated: 02-25) [Back to Table](#)

F21. OH + CCl_4 . The recommended value for $k(298\text{ K})$ was obtained by setting the Arrhenius pre-exponential factor (A) to $1 \times 10^{-11} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ and equating the activation energy (E) to the reaction endothermicity reported in this evaluation and in IUPAC. The JPL 10-6 evaluation had been based on upper limits of the rate constant reported by Cox et al.,² by Howard and Evenson,³ and by Clyne and Holt.¹ None of these experimental studies indicated any evidence for reaction between these species. (Table: 15-10, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

F23. OH + CHFCl₂ (HCFC-21). The recommended value for k(298 K) is an average of the values from the studies of Howard and Evenson,⁴ Paraskevopoulos et al.,⁶ Perry et al.,⁷ Watson et al.,⁸ Chang and Kaufman,¹ Jeong and Kaufman,⁵ and Fang et al.³ The recommended value for E/R is derived from a combined fit to the data from all but the first two studies listed above (which were only conducted at room temperature) after scaling each data set to the recommended value for k(298 K). The rate constants reported by Clyne and Holt² are significantly higher than those from the other seven studies and were not used in deriving the recommended parameters.

F24. OH + CHF₂Cl (HCFC-22). Studies of this reaction show very good agreement among both absolute and relative rate constant measurements. The recommended value for k(298 K) is an average of the values from the relative rate data of Hsu and DeMore⁷ (which has been recalculated based on the current recommendation for the rate constant of the OH + CH₄ reference reaction), and the absolute rate studies of Orkin and Khamaganov⁹, Fang et al.,⁴ Atkinson et al.,¹ Watson et al.,¹¹ Chang and Kaufman,² Paraskevopoulos et al.,¹⁰ and Jeong and Kaufman.⁸ The recommended value for E/R is derived from a combined fit to these same data sets after scaling each one to the recommended value for k(298 K). The more scattered results of Handwerk and Zellner⁵ are in general agreement. The results from the studies of Howard and Evenson⁶ and Clyne and Holt³ are significantly different from those of the other studies and were not used in the derivation.

F30. OH + CH_3CCl_3 . The recommended value for $k(298\text{ K})$ is an average of the values from the absolute rate studies of Talukdar et al.⁸ and Finlayson-Pitts et al.,² and a relative rate study of DeMore¹ (recalculated based on the current recommendation for the rate constant of the OH + CH_4 reference reaction). The temperature dependence is a fit to the data between 243 K and 379 K of Talukdar et al.⁸ These studies indicate both a lower $k(298\text{ K})$ and E/R than were reported in earlier studies by Nelson et al.,⁷ Jeong and Kaufman,³ and Kurylo et al.⁵ More recent measurements by Jiang et al.⁴ and Lancar et al.⁶ yield rate constants that are slightly higher at 298 K than this recommendation.

F31. OH + CH₃CFCl₂ (HCFC-141b). Studies of this reaction have shown that the presence of reactive impurities can have an appreciable effect on the accurate determination of its small rate constant. The recommended value of $k(298\text{ K})$ is the average of the values derived from the absolute studies of Talukdar et al.⁷ (by DF-LMR and LP-LIF, for which only data obtained with the purer sample of HCFC-141b were considered) and Lancar et al.⁴ and from the relative rate study of Huder and DeMore² (two determinations that were recalculated based on the current recommendations for the rate constants for the reference reactions $\text{OH} + \text{CH}_4$ and $\text{OH} + \text{CH}_3\text{CCl}_3$). The recommended value for E/R is derived from a combined Arrhenius fit below 400 K to the data of Talukdar et al.⁷ (without their lowest temperature data) and Lancar et al.⁴ after scaling each data set to the recommended $k(298\text{ K})$. Huder and DeMore² reported only Arrhenius expressions derived from their relative rate measurements (i.e., no actual rate constants were tabulated). Their reported values for E/R are nearly identical to the value recommended here. The results of absolute measurements of Zhang et al.⁸ (which supersede those reported in Liu et al.⁵) were complicated by secondary chemistry that may not have been completely accounted for; nevertheless, they are encompassed within the recommended 2σ uncertainty limits. Earlier measurements by Brown et al.¹ yielded significantly higher rate constants at every temperature, most likely due to the presence of very reactive impurities (such as $\text{CH}_2=\text{CCl}_2$) in their HCFC-141b sample. Talukdar et al.⁷ reported similar problems in their preliminary measurements. The room temperature result of Mörs et al.⁶ is 15% smaller than recommended but is encompassed within the recommended 2σ uncertainty limits. The room temperature rate constant reported by Kowalczyk et al.³ is inexplicably a factor of 8 smaller than recommended. The results reported by these authors for several other halocarbons vary widely (ranging from 10% agreement with recommendations to as much as 3 orders of magnitude disagreement).

F33. OH + $\text{CH}_2\text{ClCF}_2\text{Cl}$ (HCFC-132b). The recommended parameters are derived from the data of Watson et al.,² which were corrected by these authors for the presence of alkene impurities. The data of Jeong et al.,¹ indicating faster rate constants, may have been affected by such impurities; hence they were not included in deriving the recommendation.

(Table: 02-25, Note: 02-25, Evaluated: 02-25) [Back to Table](#)

- (1) Jeong, K. M.; Hsu, K. J.; Jeffries, J. B.; Kaufman, F. Kinetics of the reactions of OH with C_2H_6 , CH_3CCl_3 , $\text{CH}_2\text{ClCHCl}_2$, $\text{CH}_2\text{ClCClF}_2$, and CH_2FCF_3 . *J. Phys. Chem.* **1984**, 88, 1222-1226, doi:10.1021/j150650a041.

F34. OH + CH₂FCFCl₂ (HCFC-132c). The recommended Arrhenius parameters are derived from the data of Orkin et al.¹
(Table: 15-10, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

- (1) Orkin, V. L.; Khamaganov, V. G.; Kasimovskaya, E. E.; Guschin, A. G. Photochemical properties of some Cl-containing halogenated alkanes. *J. Phys. Chem. A* **2013**, *117*, 5483-5490, doi:10.1021/jp400408y.

F35. OH + CH₂ClCF₃ (HCFC-133a). The recommended parameters are derived from the data of McGillen et al.,⁶ which is the only study to fully cover the lower temperatures of atmospheric interest. The value of the rate constant at room temperature from Howard and Evenson⁵ is in good agreement with the recommended value for k(298 K), while systematic differences exist with the k(298 K) values derived from the absolute measurements of Handwerk and Zellner⁴ (~50%) and Fang et al.³ (~60%) and from the relative rate study of DeMore² (~15%) using OH + CH₃CCl₃ as the reference reaction. Despite these systematic differences, the recommended temperature dependences derived from the last three studies listed above are in reasonable agreement with the recommended E/R. The data of Clyne and Holt¹ are quite scattered, and the values above room temperature are considerably higher than those from other studies. Hence, these data were not used in deriving the recommended parameters.

F36. OH + CHCl₂CF₂Cl (HCFC-122). The recommended parameters are derived from a combined fit to the data of Orkin and Khamaganov² (below 400 K) and DeMore¹ (two determinations which have been recalculated based on the current recommendations for the rate constants of the OH + CH₂Cl₂ and OH + CHCl₂CF₃ reference reactions).

(Table: 02-25, Note: 02-25, Evaluated: 02-25) [Back to Table](#)

- (1) DeMore, W. B. Experimental and estimated rate constants for the reactions of hydroxyl radicals with several halocarbons. *J. Phys. Chem.* **1996**, *100*, 5813-5820.
- (2) Orkin, V. L.; Khamaganov, V. G. Determination of rate constants for reactions of some hydrohaloalkanes with OH radicals and their atmospheric lifetimes. *J. Atmos. Chem.* **1993**, *16*, 157-167.

F37. OH + CHFClCFCl₂ (HCFC-122a). The recommended value for k(298 K) is an average of the results from the relative rate study of Hsu and DeMore¹ (recalculated based on the current recommendation for the rate constant for the OH + CH₃CHF₂ reference reaction, as discussed in the note for that reaction) and from the absolute rate study of Orkin et al.² The recommended value for E/R is derived from a combined fit to the data of both studies below 400 K after scaling both data sets to the recommended k(298 K).

F38. OH + CHCl₂CF₃ (HCFC-123). The recommended value of $k(298\text{ K})$ is the average of the values from the absolute studies of Gierczak et al.³ (two determinations), Liu et al.,⁶ and Yamada et al.,⁹ and from the relative rate study by Hsu and DeMore⁵ (recalculated based on the current recommendation for the rate constant for the OH + CH₃CHF₂ reference reaction, as discussed in the note for that reaction). The recommendation for the temperature dependence is derived from a fit to the data of these investigations after scaling each data set to the recommended value for $k(298\text{ K})$. The temperature dependence data of Nielsen,⁷ Watson et al.,⁸ Clyne and Holt,² and Brown et al.¹ and the room temperature data of Howard and Evenson⁴ were not used in deriving the recommended parameters.

F39. OH + CHFClCF₂Cl (HCFC-123a). The recommended parameters are derived from the data of Orkin and Khamaganov.¹

(Table: 02-25, Note: 02-25, Evaluated: 02-25) [Back to Table](#)

- (1) Orkin, V. L.; Khamaganov, V. G. Determination of rate constants for reactions of some hydrohaloalkanes with OH radicals and their atmospheric lifetimes. *J. Atmos. Chem.* **1993**, *16*, 157-167.

F40. OH + CHFClCF₃ (HCFC-124). The recommended value for $k(298\text{ K})$ is an average of the values from the studies of Watson et al.,⁴ Gierczak et al.,¹ (2 studies), Yamada et al.,⁵ and Hsu and DeMore³ (two relative rate determinations, which have been recalculated based on the current recommendations for the rate constants of the OH + CH₄ and OH + CHF₂CHF₂ reference reactions). The room temperature rate constant of Howard and Evenson² is considerably higher than these other values and was not included in the average. The recommended temperature dependence is an average of the dependencies derived from these same studies (but using only data below 400 K from Gierczak et al.¹ and Yamada et al.⁵).

F41. OH + CH₃CH₂CH₂Cl. The recommended Arrhenius parameters are derived from the data of Yujing and Mellouki.³ The results from the investigations by Markert and Nielsen² and by Donaghy et al.¹ exhibit considerably more scatter but are, to a large part, encompassed within the 2σ confidence limits of this recommendation.

(Table: 15-10, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

F43. OH + CH₃CF₂CFCl₂ (HCFC-243cc). The recommended Arrhenius parameters are derived from the data of Nelson et al.¹ The uncertainties have been assigned to reflect the assumption that the rate constant for this reaction should be less than that for OH + CH₃CF₂Cl.

(Table: 02-25, Note: 02-25, Evaluated: 02-25) [Back to Table](#)

- (1) Nelson, D. D., Jr.; Zahniser, M. S.; Kolb, C. E. Chemical kinetics of the reactions of the OH radical with several hydrochlorofluoropropanes. *J. Phys. Chem.* **1992**, *96*, 249-253.

F44. OH + CHCl₂CF₂CF₃ (HCFC-225ca). The recommended value for k(298 K) is an average of the values from Nelson et al.² and Zhang et al.³ The recommendation for E/R is derived from the data of Nelson et al.² The temperature-dependence data of Brown et al.¹ were not considered because the relatively large rate constants at and below room temperature and the Arrhenius curvature are suggestive of sample impurities. The temperature dependence results of Zhang et al.³ are in reasonable agreement with those of Nelson et al.² over the temperature range of measurement overlap. However, the complete Zhang et al.³ data set yields a value for E/R much larger than currently recommended for the OH + CHCl₂CF₃ (HCFC-123) reaction, for which the activation energy should be similar.

(Table: 02-25, Note: 02-25, Evaluated: 02-25) [Back to Table](#)

F45. OH + CF₂ClCF₂CH₂Cl (HCFC-225cb). The recommended parameters are derived from a combined fit to the temperature-dependence data of Nelson et al.¹ and Zhang et al.,² which are in excellent agreement. (Table: 15-10, Note: 02-25, Evaluated: 02-25) [Back to Table](#)

- (1) Nelson, D. D., Jr.; Zahniser, M. S.; Kolb, C. E. Chemical kinetics of the reactions of the OH radical with several hydrochlorofluoropropanes. *J. Phys. Chem.* **1992**, 96, 249-253.
- (2) Zhang, Z.; Liu, R.; Huie, R. E.; Kurylo, M. J. Rate constants for the gas phase reactions of the OH radical with CF₃CF₂CHCl₂ (HCFC-225ca) and CF₂ClCF₂CHClF (HCFC-225cb). *Geophys. Res. Lett.* **1991**, 18, 5-7.

F46. OH + CF₃CH₂CFCl₂ (HCFC-234fb). The recommended value for k(298 K) is from the relative rate study of Barry et al.¹ The value for E/R is estimated as being slightly less than that for OH + CF₃CH₂CF₃. (Table: 10-6, Note: 10-6, Evaluated: 10-6) [Back to Table](#)

- (1) Barry, J.; Locke, G.; Scollard, D.; Sidebottom, H.; Treacy, J.; Clerbaux, C.; Colin, R.; Franklin, J. 1,1,1,3,3,3-pentafluorobutane (HFC-365mfc): Atmospheric degradation and contribution to radiative forcing. *Int. J. Chem. Kinet.* **1997**, 29, 607-617.

F47. OH + CH₂=CHCl. The recommended value for k(298 K) is an average of the values reported by Howard,¹ Perry et al.,³ Liu et al.,² and Yamada et al.⁴ The recommended value for E/R is an average of the values for this parameter derived from fits to the data of Perry et al., Liu et al., and Yamada et al. at temperatures below about 400 K. In the 400–500 K region, the rate constant levels off before increasing at higher temperatures, suggesting the stronger importance of an abstraction mechanism at the higher temperatures. As discussed in note for the OH + CH₂=CHF reaction, the recommended rate constant represents the high-pressure limit for this reaction. (Table: 02-25, Note: 10-6, Evaluated: 10-6) [Back to Table](#)

F48. OH + (E)-CHCl=CHCl. The recommended value for k(298 K) is an average of the values reported in the absolute rate studies of Abbatt and Anderson,¹ Zhang et al.,⁵ Yamada et al.,⁴ and Canosa-Mas et al.² The recommended value for E/R is derived from a combined fit to the data below 400 K from the first three studies listed above after scaling to the recommended value for k(298 K). The data from the room temperature relative rate study of Tuazon et al.³ are significantly lower than those in the absolute studies and were not used in deriving the recommended value for k(298 K). F49. OH + (Z)-CHCl=CHCl. The recommended value for $k(298\text{ K})$ is an average of the values reported in the absolute rate studies of Abbatt and Anderson,¹ and Zhang et al.³ The recommended value for E/R is derived from a combined fit to the data of these two studies after scaling to the recommended value for $k(298\text{ K})$. The data from the room temperature relative rate study of Tuazon et al.² were not used in deriving the recommended value for $k(298\text{ K})$. While in agreement with the recommended value, this same study yielded significantly different results than recommended for the *trans* isomer.
(Table: 15-10, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

- (1) Abbatt, J. P. D.; Anderson, J. G. High-pressure discharge flow kinetics and frontier orbital mechanistic analysis for OH + CH₂CCl₂, *cis*-CHClCHCl, *trans*-CHClCHCl, CFCICF₂, and CF₂CCl₂ → Products. *J. Phys. Chem.* **1991**, 95, 2382-2390.

F50. OH + CH₂=CCl₂. The recommended value for $k(298\text{ K})$ is an average of the values reported by Abbatt and Anderson,¹ Yamada et al.⁶, and Zhang et al.⁷ The room temperature results of Edney et al.,³ Tuazon et al.,⁵ and Canosa-Mas et al.² lie somewhat outside of the range of the other studies and were not used in deriving the recommendation. The recommended value for E/R is derived from a combined fit to the data of Abbatt and Anderson,¹ Yamada et al.⁶, and Zhang et al.⁷ after scaling each data set to the value recommended for $k(298\text{ K})$. The data of Kirchner et al.⁴ were not used in deriving the recommended parameters since they were obtained at very low pressure, and the much stronger temperature dependence obtained may be indicative of a pressure dependence above room temperature. As discussed in the note for the OH + CH₂=CHF reaction, the recommended rate constant represents the high pressure limit for this reaction.

F51. OH + CHCl=CCl₂. The recommended value for $k(298\text{ K})$ is the mean of the values reported by Howard,³ Chang and Kaufman,¹ Kirchner et al.,⁵ Klopffer et al.,⁶ Edney et al.,² and Tichenor et al.⁷ The recommended value of E/R is an average of values for this parameter derived by Chang and Kaufman,¹ Kirchner et al.,⁵ and Tichenor et al.⁷ The value for $k(298\text{ K})$ derived from a relative rate study by Winer et al.⁸ is a factor of ~2 greater than the other values and is not considered in deriving the recommended value. An absolute study by Jiang et al.⁴ yielding a significantly higher value for $k(298\text{ K})$, as well as a considerably stronger temperature

dependence ($E/R = -970$ K), is assumed to be superseded by Tichenor et al.⁷ As discussed in the note for the $\text{OH} + \text{CH}_2=\text{CHF}$ reaction, the recommended rate constant represents the high pressure limit for this reaction. (Table: 02-25, Note: 10-6, Evaluated: 10-6) [Back to Table](#)

F52. $\text{OH} + \text{CCl}_2=\text{CCl}_2$. The recommended value for $k(298\text{ K})$ is the mean of the values reported by Howard,² Chang and Kaufman,¹ and Kirchner et al.³ The room temperature value reported by Winer et al.⁵ is more than a factor of 10 greater and was not used in deriving the recommendation. The recommended value for E/R is an average of values for this parameter derived by Chang and Kaufman¹ and Kirchner et al.³ A study by Tichenor et al.⁴ yields a value for $k(298\text{ K})$ slightly lower than these other studies, but a temperature dependence less than half of that recommended. While the results of Tichenor et al.⁴ were not used in deriving the recommendations, they are encompassed within the 2σ confidence limits. As discussed in the note for the $\text{OH} + \text{CH}_2=\text{CHF}$ reaction, the recommended rate constant represents the high pressure limit for this reaction.

(Table: 02-25, Note: 10-6, Evaluated: 10-6) [Back to Table](#)

- (1) Chang, J. S.; Kaufman, F. Kinetics of the reactions of hydroxyl radicals with some halocarbons: CHFCl_2 , CHF_2Cl , CH_3CCl_3 , C_2HCl_3 , and C_2Cl_4 . *J. Chem. Phys.* **1977**, *66*, 4989-4994.

F53. $\text{OH} + \text{CF}_2=\text{CFCl}$. The recommended Arrhenius parameters are derived from the data of Abbatt and Anderson.¹ The value for $k(298\text{ K})$ reported by Howard² is in very good agreement with that recommended here.

(Table: 15-10, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

- (1) Abbatt, J. P. D.; Anderson, J. G. High-pressure discharge flow kinetics and frontier orbital mechanistic analysis for $\text{OH} + \text{CH}_2\text{CCl}_2$, *cis*- CHClCHCl , *trans*- CHClCHCl , CFClCF_2 , and $\text{CF}_2\text{CCl}_2 \rightarrow \text{Products}$. *J. Phys. Chem.* **1991**, *95*, 2382-2390.
- (2) Howard, C. J. Rate constants for the gas-phase reactions of OH radicals with ethylene and halogenated ethylene compounds. *J. Chem. Phys.* **1976**, *65*, 4771-4777.

F54. OH + (E)-CHCl=CHCF₃. The recommended value for k(298K) is an average of the values determined by Orkin et al.² and Gierczak et al.¹ The value reported in the room temperature relative rate study by Sulbaek-Andersen et al.,³ while only about 15% larger than the recommended value, has much greater uncertainty due to uncertainties in the reference reaction rate constants. The data reported by Orkin et al.² and Gierczak et al.¹ exhibit somewhat different temperature dependences. Orkin et al.² report significant curvature in the Arrhenius plot over the temperature range 220–370 K that is best fit by a modified three-parameter Arrhenius expression

$$k(T) = 1.03 \times 10^{-13} (T/298)^{2.29} \exp(+384/T).$$

This curvature is not seen in the data reported by Gierczak et al.¹ The recommended value for E/R is an average of the E/R values derived from the individual fits to the Orkin et al.² and Gierczak et al.¹ data for T < 300 K.

(Table: 15-10, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

- (1) Gierczak, T.; Baasandorj, M.; Burkholder, J. B. OH + (E)- and (Z)- 1-chloro-3,3,3-trifluoropropene- 1 (CF₃CH=CHCl) reaction rate coefficients: Stereoisomer-dependent reactivity. *J. Phys. Chem. A* **2014**, *118*, 11015-11025, doi:10.1021/jp509127h.
- (2) Orkin, V. L.; Martynova, L. E.; Kurylo, M. J. Phys. Chem. A* **2014**, *118*, 5263-5271, doi:10.1021/jp5018949.
- (3) Sulbaek Andersen, M. P.; Nilsson, E. J. K.; Nielsen, O. J.; Johnson, M. S.; Hurley, M. D.; Wallington, T. J. Atmospheric chemistry of *trans*-CF₃CH=CHCl: Kinetics of the gas-phase reactions with Cl atoms, OH radicals, and O₃. *J. Photochem. and Photobiol. A: Chem.* **2008**, *199*, 92-97, doi:10.1016/j.jphotochem.2008.05.013.

F55. OH + (Z)-CHCl=CHCF₃. The recommended Arrhenius parameters are derived from a fit to the data of Gierczak et al.¹ for T < 298 K. Above 298 K, the Arrhenius plot exhibits pronounced curvature such that the entire data set from 213 K–373 K is best fit by a modified three-parameter Arrhenius expression

$$k(T) = 1.15 \times 10^{-13} (T/298)^{1.38} \exp(+628/T).$$

Below 298 K this expression and the simple Arrhenius parameterization yield nearly identical values for the rate constant.

F56. OH + CHF₂OCHClCF₃ (Isoflurane). The recommended value for k(298 K) is an average of the results from Tokuhashi et al.,⁵ Langbein et al.,³ and Sulbaek-Andersen et al.⁴ The recommended value for E/R is derived from a fit to the two temperature dependent data sets of Tokuhashi et al.⁵ The room temperature data determined in the discharge-flow experiments by Brown et al.² and Beach et al.¹ lie about 30% higher than recommended here. However, the data from Beach et al.¹ above room temperature agree well with those of Tokuhashi et al.⁵

F60. HO_2 + Cl. The recommendations for the two reaction channels are based upon the results of Hickson and Keyser,⁵ who measured both channels using the discharge flow-resonance fluorescence technique coupled with infrared diode laser spectroscopy, detecting HO, HO_2 , Cl, and HCl; by Lee and Howard,⁶ who measured the total rate constant and the OH + ClO channel using a discharge flow system with laser magnetic resonance detection of HO_2 , OH, and ClO; and by Riffault et al.,⁹ who measured the total rate constant and the OH + ClO channel using the discharge flow mass spectrometric technique. The studies of Lee and Howard and Riffault et al. suggest that the total rate constant is temperature independent with a value of $(4.2 \pm 0.7) \times 10^{-11}$ and $(4.4 \pm 0.6) \times 10^{-11}\text{ cm}^3\text{ molecule}^{-1}\text{ s}^{-1}$ over the temperature range 250–420 K and 230–360 K, respectively. The Hickson and Keyser study concludes that the HCl channel may be represented as $(1.4 \pm 0.3) \times 10^{-11} \exp[(269 \pm 58)/T]$ for temperatures from 256 to 296 K, while the OH channel is given by $(12.7 \pm 4.1) \times 10^{-11} \exp[-(801 \pm 94)/T]$ for temperatures of 226–336 K, the sum of which yields $4.3 \times 10^{-11}\text{ cm}^3\text{ molecule}^{-1}\text{ s}^{-1}$ at 298 K with a small temperature dependence. These values for the total rate constant are in agreement with the results of indirect studies relative to $\text{Cl} + \text{H}_2\text{O}_2$ (Leu and DeMore,⁷ Poulet et al.,⁸ and

Burrows et al.¹) or to $\text{Cl} + \text{H}_2$ (Cox³). The contribution of the reaction channel producing $\text{OH} + \text{ClO}$ (22% at room temperature) is much higher than the upper limit reported by Burrows et al. (1% of total reaction). Cattell and Cox,² using a molecular modulation-UV absorption technique over the pressure range 50–760 Torr, report results in good agreement with those of Lee and Howard both for the overall rate constant and for the relative contribution of the two reaction channels. A study by Dobis and Benson⁴ reports a total rate constant in good agreement with this recommendation but a much lower contribution ($5 \pm 3\%$) of the channel producing $\text{OH} + \text{ClO}$. The equilibrium constant for the channel producing $\text{ClO} + \text{OH}$ can be calculated with excellent accuracy. The recommended value for this channel comes from the combination of this equilibrium constant and the rate constant for the reverse reaction.

F61. $\text{HO}_2 + \text{ClO}$. The recommended value for $k(298 \text{ K})$ is based on studies by Hickson et al.,⁴ Nickolaisen et al.,⁸ Knight et al.,⁵ and Stimpfle et al.,¹⁰ which studied the reaction as a function of temperature. Earlier room temperature measurements by Reimann and Kaufman,⁹ Leck et al.,⁶ Burrows and Cox,¹ and Cattell and Cox² are slightly lower than the current recommendation. The studies of Cattell and Cox and Nickolaisen et al. were performed over extended pressure ranges and did not observe a pressure dependence. The most recent studies find the T-dependence to be characterized by linear Arrhenius behavior over the entire temperature range and do not support the finding of Stimpfle et al. of non-Arrhenius behavior. The recommended value for E/R is based on an average of individual E/R values for each of the first four studies listed above over their entire temperature ranges. The two most probable pairs of reaction products are (1) $\text{HOCl} + \text{O}_2$ and (2) $\text{HCl} + \text{O}_3$. Finkbeiner et al.,³ using matrix isolation/ FTIR spectroscopy, studied product formation between 210 and 300 K at 700 Torr. HOCl was observed to be the dominant product (>95% at all temperatures). Upper limits ranging from 0.3% to 2% have been determined for the channel (2) room temperature branching ratio by Leu,⁷ Leck et al., Knight et al., and Finkbeiner et al. Slightly larger branching ratio (<5%) upper limit values for k_2/k were determined at temperatures below 250 K by Finkbeiner et al. and Leck et al. However, no direct evidence of product channels other than channel (1) was found. Theoretical calculations are in generally good agreement on the structures and relative energetics of the intermediates in this reaction system (see the summary in Hickson et al.⁴). In particular, Xu et al.¹¹ reported quantum chemistry and master equation calculations that are in reasonable agreement with the experiments. For atmospheric conditions, their calculations identified only two significant channels: the pressure-independent abstraction reaction to form $\text{HOCl} + \text{O}_2$ and pressure-dependent formation of HOOCl , which has thermal decomposition lifetimes ranging from hours to days under stratospheric conditions. At 250 K and 400 Torr of N_2 , they calculate that the abstraction reaction constitutes ~60–70% of the total rate constant for $\text{ClO} + \text{HO}_2$, supporting the notion that a significant pressure-dependence exists. Further experimental studies on the formation, lifetime, and atmospheric fate of HOOCl are warranted.

F62. $\text{H}_2\text{O} + \text{ClONO}_2$. The recommendation is based on the upper limits to the homogeneous bimolecular rate constant reported by Atkinson et al.¹ and Hatakeyama and Leu.^{2,3} Atkinson et al. observed by FTIR analysis the decay of ClONO_2 in the presence of H_2O in large-volume (2500 and 5800 liters) Teflon or Teflon-coated chambers. Their observed decay rate gives an upper limit to the homogeneous gas phase rate constant, and they conclude that the decay observed is due to heterogeneous processes. Hatakeyama and Leu, using a static photolysis system with FTIR analysis, derived a similar upper limit. Rowland et al.⁴ concluded that the decay they observed resulted from rapid heterogeneous processes. The homogeneous reaction is too slow to have any significant effect on atmospheric chemistry.

F63. $\text{NO} + \text{OCIO}$. The Arrhenius parameters are estimated based on 298 K data reported by Bemand et al.¹ Temperature data by Li et al.² are in good agreement with Bemand et al. at 298 K and display a negative temperature dependence over the range 220–367 K. However, the Li et al. data appear to be complicated by the secondary reaction of Cl with OCIO .

- F65. NO₃ + HCl.** The recommended upper limit is that reported by Mellouki et al.³ in a study using DF-EPR techniques. This upper limit shows that this reaction is of negligible importance in stratospheric chemistry. Somewhat lower upper limits have been reported by Cantrell et al.² and Canosa-Mas et al.¹; the latter study also reports Arrhenius parameters at higher temperatures (333–473 K).

- F66. HO₂NO₂ + HCl.** This upper limit is based on results of static photolysis-FTIR experiments reported by Leu et al.¹
(Table: 90-1, Note: 90-1, Evaluated: 10-6) [Back to Table](#)
- (1) Leu, M.-T.; Hatkeyama, S.; Hsu, K. J. Rate constants for reactions between atmospheric reservoir species. 1. HCl. *J. Phys. Chem.* **1989**, *93*, 5778-5784, doi:10.1021/j100352a026.
- F67. Cl + O₃.** The results reported for k(298 K) by Watson et al.,¹³ Zahniser et al.,¹⁴ Kurylo and Braun,⁸ Clyne and Nip,⁴ Nicovich et al.,¹⁰ Seeley et al.,¹¹ and Beach et al.¹ are in good agreement, and have been used to determine the recommended value at this temperature. The values reported by Leu and DeMore⁹ (due to the large reported uncertainties) and Clyne and Watson⁵ (the value is inexplicably high) are not considered. The seven studies used for the k(298 K) recommendation report rate constants that agree to within 30-40% over the temperature range 205–300 K and all report similar values for the Arrhenius activation energy with the exception of Nicovich et al. and Seeley et al. who obtained significantly weaker temperature dependences. Nevertheless, there is no reason to prefer any one set of data over any other; therefore, the recommended E/R is the mean of the seven values for this parameter between 205 and 300 K. DeMore⁷ directly determined the ratio k(Cl + O₃)/k(Cl + CH₄) at 197–217 K to be within 15% of that calculated from the absolute rate constant values recommended here.
- Vanderzanden and Birks¹² have interpreted their observation of oxygen atoms in this system as evidence for some production (0.1–0.5%) of O₂ (¹Σ) in this reaction. The possible production of singlet molecular oxygen in this reaction has also been discussed by DeMore,⁶ in connection with the Cl₂ photosensitized decomposition of ozone. However Choo and Leu³ were unable to detect O₂(¹Σ) or O₂(¹Δ) in the Cl + O₃ system and set upper limits to the branching ratios for their production of 5 × 10⁻⁴ and 2.5 × 10⁻², respectively. They suggested two possible mechanisms for the observed production of oxygen atoms, involving reactions of vibrationally excited ClO radicals with O₃ or with Cl atoms, respectively. Burkholder et al.,² in a study of infrared line intensities of the ClO radical, present evidence in support of the second mechanism. In their experiments with excess Cl atoms, the vibrationally excited ClO radicals produced in the Cl + O₃ reaction can react with Cl atoms to give Cl₂ and oxygen atoms, which can then remove additional ClO radicals. These authors point out the possibility for systematic error from assuming a 1:1 stoichiometry for [Cl]:[O₃]₀ when using the Cl + O₃ reaction as a quantitative source of ClO radicals for kinetic and spectroscopic studies.

F68. $Cl + H_2$. The recommended value for $k(298\text{ K})$ is an average of the values measured by Westenberg and deHaas,¹² Lee et al.,⁸ Miller and Gordon,⁹ and Kita and Stedman.⁶ The value of $k(298\text{ K})$ derived in the flash photolysis - resonance fluorescence study of Davis et al.⁴ agrees with these studies but was likely overestimated by $\sim 10\%$ (the authors assumed that the fluorescence signal, I_f was proportional to $[Cl]^{0.9}$, whereas a linear relationship between I_f and $[Cl]$ probably held under their experimental conditions). Room temperature determinations by Kumaran et al.⁷ (from a study that was actually focused primarily on high temperature measurements) and Eberhard et al.⁵ (focused on obtaining yields of HCl product in different vibrational levels) are both in reasonable agreement with the recommendation, as are the results from the relative rate studies by Su et al.¹¹ and by Rodebush and Klingelhofer.¹⁰ The value for E/R is derived from a fit to the data at temperatures below 300 K reported by Westenberg and deHaas,¹² Lee et al.,⁸ and Miller and Gordon.⁹ The value is in good agreement with that determined by Adusei and Fontijn,¹ although these data lie systematically lower than the results from other studies. Extrapolation above room temperature using the recommended Arrhenius parameters is in reasonable agreement with the data of Benson et al.³ and Kita and Stedman.⁶ For a discussion of the large body of rate data at high temperatures, see the review by Baulch et al.² Miller and Gordon⁹ and Kita and Stedman⁶ also measured the rate of the reverse reaction and found the ratio to be in good agreement with equilibrium constant data.

F69. Cl + H₂O₂. The absolute rate coefficients determined at ~298 K by Watson et al.,⁶ Leu and DeMore,³ Michael et al.,⁴ Poulet et al.,⁵ and Keyser² range in value from (3.6–6.2) × 10⁻¹³. The studies of Michael et al., Keyser, and Poulet et al. are presently considered to be the most reliable. The recommended Arrhenius parameters are those reported by Keyser. The A-factor reported by Michael et al. is considerably lower than that expected from theoretical considerations and may possibly be attributed to decomposition of H₂O₂ at temperatures above 300 K. The data of Michael et al. at and below 300 K are in good agreement with the Arrhenius expression reported by Keyser. Heneghan and Benson,¹ using mass spectrometry, confirmed that this reaction proceeds only by the abstraction mechanism giving HCl and HO₂ as products.

F70. Cl + NO₃. The recommended value at room temperature is based on the discharge flow-EPR study of Mellouki et al.⁵ and the discharge flow-mass spectrometric study of Becker et al.¹ The results of these direct absolute rate studies are preferred over results of the earlier relative rate studies of Cox et al.,³ Burrows et al.,² and Cox et al.,⁴ in all of which NO₃ was monitored in the photolysis of Cl₂-ClONO₂-N₂ mixtures. Complications in the chemistry of the earlier systems probably contributed to the spread in reported values. This radical-radical reaction is expected to have negligible temperature dependence, which is consistent with the results from the study of Cox et al.⁴ in which the complications must have been temperature independent.

- F71. Cl + N₂O.** This rate coefficient has been determined in a study of the halogen-catalyzed decomposition of nitrous oxide at about 1000 K by Kaufman et al.¹ The largest value reported was 10^{-17} cm³ molecule⁻¹ s⁻¹, with an activation energy of 34 kcal/mol. Extrapolation of these results to low temperature shows that this reaction cannot be of any significance in atmospheric chemistry. Kinetic isotope effects observed by Lesar et al.² are consistent with a reaction transition state where the chlorine atom is bonded to the oxygen atom of nitrous oxide with a planar trans arrangement of atoms.

- F72. Cl + HNO₃.** The recommended upper limit at room temperature is that reported in the study of Wine et al.,⁵ in which long-path laser absorption spectroscopy was used to look for the appearance of NO₃ following the pulsed laser photolysis of Cl₂-HNO₃ mixtures, with no evidence for NO₃ production observed. In the same study, a less sensitive upper limit was derived from monitoring Cl atom decay by resonance fluorescence. A less sensitive upper limit was also found in the discharge flow-EPR study of Zagogianni et al.⁶ Higher values obtained in earlier studies (Leu and DeMore,³ Kurylo et al.,² and Clark et al.¹), as well as the higher temperature results of Poulet et al.⁴ are not used.

- F73. Cl + HO₂NO₂.** The only study of this reaction is by Simonaitis and Leu¹ using the low pressure discharge flow technique coupled with resonance fluorescence detection of Cl and mass spectrometric detection of HO₂NO₂ ion fragments. Consistent results were obtained monitoring either Cl or HO₂NO₂ decays and retrieved rate constants were less than 1×10^{-13} cm³ molecule⁻¹ s⁻¹ for all conditions. Impurities in the HO₂NO₂ sample (especially H₂O₂) complicated the measurements. A limited temperature study over the 296-399 K range suggests that E/R is in the range of 500-1500 K. Given the experimental difficulties, only an upper limit is recommended for the reaction rate.

- F74. Cl + CH₄.** The recommended value for k(298 K) = 1.0×10^{-13} cm³ molecule⁻¹ s⁻¹ is obtained as an average of the values derived from the absolute rate constant studies of Manning and Kurylo,¹⁵ Whytock et al.,²⁸ Michael and Lee,¹⁷ Lin et al.,¹⁴ Zahniser et al.,²⁹ Keyser,⁸ Ravishankara and Wine,²² Heneghan et al.,⁷ (which is assumed to supersede the results obtained by Baghal-Vayjooee et al.¹), Dobis and Benson,⁶ Sawerysyn et al.,²³ Lazarou et al.,¹¹ Beichert et al.,² Seeley et al.,²⁵ Pilgrim et al.,¹⁸ Mellouki et al.,¹⁶ Wang and Keyser,²⁶ and Bryukov et al.,³ all of which fall in the range $(0.9-1.13) \times 10^{-13}$ cm³ molecule⁻¹ s⁻¹. Other absolute studies by Davis et al.,⁵ Clyne and Walker,⁴ Poulet et al.,¹⁹ Leu and DeMore,¹³ Watson et al.,²⁷ and Schlyer et al.²⁴ yield rate constant values slightly higher than those of the aforementioned studies. In some cases, this may be due to uncertainties in correcting the data for Cl atom loss via reaction with trace levels of ethane and propane in the methane samples used. Thus, these results were not used in deriving the recommended value for k(298 K). The values derived for k(298 K) from the competitive chlorination studies of Pritchard et al.,²⁰ Pritchard et al.,²¹ Knox,⁹ Knox and Nelson,¹⁰ Lee and Rowland,¹² and Lin et al.¹⁴ are in the range $(0.8-1.6) \times 10^{-13}$ cm³ molecule⁻¹ s⁻¹ when the original data are referenced to the presently recommended rate constant values for the reference reactions of Cl with H₂ and C₂H₆; these studies were not used in deriving the

recommended value for $k(298\text{ K})$. In particular, the reference reaction $\text{Cl} + \text{C}_2\text{H}_6$ has a rate constant more than three orders of magnitude greater than that of $\text{Cl} + \text{CH}_4$, thus making it far from ideal for a competitive chlorination study.

Nine of the aforementioned absolute studies used in the derivation of $k(298\text{ K})$ were performed at temperatures below 300 K (Manning and Kurylo,¹⁵ Whytock et al.,²⁸ Lin et al.,¹⁴ Zahniser et al.,²⁹ Keyser,⁸ Ravishankara and Wine,²² Heneghan et al.,⁷ Seeley et al.,²⁵ and Wang and Keyser²⁶). The agreement among all studies below 300 K is reasonably good, with values of E/R ranging from 1170 K to 1320 K. The recommended $E/R = 1270\text{ K}$ is derived from a combined fit to all data below 300 K from these nine studies after scaling each of the individual data sets to the recommended $k(298\text{ K})$. Systematic differences in activation energies are apparent when calculated using data obtained below 300 K versus data from above 300 K. Three studies have been performed over the temperature region between 200 and 500 K (Whytock et al.,²⁸ Zahniser et al.,²⁹ and Keyser⁸), and in each case non-linear Arrhenius behavior was observed.

The curvature in the Arrhenius plot over the temperature range from 180 K to 410 K can be fit by the three-parameter expression

$$k(180\text{--}410\text{ K}) = 2.36 \times 10^{-12} (T/298)^{1.37} \exp(-939/T).$$

Below 307 K, this expression yields values for $k(T)$ within 2% of those calculated using the Arrhenius parameters recommended above. The three-parameter expression is recommended for use in calculating the rate constants from the results of relative rate studies conducted both above and below room temperature in which the $\text{Cl} + \text{CH}_4$ reaction is used as the reference.

Ravishankara and Wine²² observed that at temperatures below 240 K the apparent bimolecular rate constant was dependent on the chemical composition of the reaction mixture. They suggested that the effect was due to a non-equilibration of the $^2\text{P}_{1/2}$ and $^2\text{P}_{3/2}$ states of atomic chlorine when the mixture did not contain an efficient spin equilibrator, and thus the results obtained at lower pressure using the discharge flow and competitive chlorination techniques may be in error at the lower temperatures (<240 K). However, subsequent studies did not reproduce this observation. Therefore, only data obtained by Ravishankara and Wine²² above 240 K were used here in the global fit.

F75. Cl + CH₃D. The recommended value for k(298 K) is an average of the relative rate determinations by Feilberg et al.,² Sauer et al.,³ Saueressig et al.,⁴ (two measurements), and Tyler et al.,⁵ all of which are in excellent agreement. The recommended value of E/R is derived from a combined fit to the data reported in the last three papers listed above after scaling each individual data set to the recommended k(298 K). The uncertainty in the data reported by Boone et al.¹ (both in the measured rate constant ratio and in the temperature of the experiment) significantly exceeds those of other studies. Hence, these data were not used in the evaluation. However, this result is encompassed within the recommended 2σ uncertainty. The result originally reported by Wallington and Hurley⁶ was corrected in a personal communication from the authors as later reported by Saueressig et al.⁴ The corrected value is in excellent agreement with the recommendation at the temperature of the experiment. Note that a three-parameter expression recommended for the reaction Cl + CH₄ was used to derive the rate constants from the rate constant ratios reported in the original papers. The excellent agreement among all of the results reported for the reaction between Cl and CH₃D used in deriving this recommendation could be well encompassed within uncertainty limits calculated with f(298 K) = 1.03 and g = 50. However, all of the above mentioned studies are relative rate measurements that utilize the same reference reaction, Cl + CH₄. Thus, all of these determinations can be affected by the same systematic uncertainty in the reference rate constant. The recommended uncertainty parameters, f(298 K) and g account for this added uncertainty.

F76. $\text{Cl} + \text{H}_2\text{CO}$. The results from five of the six published studies (Michael et al.,⁴ Anderson and Kurylo,¹ Niki et al.,⁵ Fasano and Nogar,² and Poulet et al.⁶) are in good agreement at ~ 298 K, but are $\sim 50\%$ greater than the value reported by Foon et al.³ The recommended value at 298 K is obtained by combining the absolute values reported by Michael et al., Anderson and Kurylo, and Fasano and Nogar, with the values obtained by combining the ratio of $k(\text{Cl} + \text{H}_2\text{CO})/k(\text{Cl} + \text{C}_2\text{H}_6)$ reported by Niki et al. (1.3 ± 0.1) and by Poulet et al. (1.16 ± 0.12) with the recommended value of $5.7 \times 10^{-11} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ for $k(\text{Cl} + \text{C}_2\text{H}_6)$ at 298 K. The recommended value of E/R is obtained from a least squares fit to all the data reported in Michael et al. and in Anderson and Kurylo. The A-factor was adjusted to agree with the recommended value at 298 K. (Table: 82-57, Note: 82-57, Evaluated: 82-57) [Back to Table](#)

F77. $\text{Cl} + \text{HC(O)OH}$. The room temperature kinetics of this reaction have been studied by Wallington et al.³ and Li et al.¹ Wallington et al. used a relative rate technique at atmospheric pressure, while Li et al. employed flash photolysis at a pressure of 10 Torr. The results of the two studies are in excellent agreement and have been averaged together to derive the recommended value for $k(298 \text{ K})$. Reaction products have been investigated by Tyndall et al.² at room temperature and 700 Torr pressure. They measured the CO_2 yield to be $96 \pm 5\%$ and suggested that the HOCO complex reacted with either O_2 or Cl_2 in their experiment to give the observed product.

F78. $\text{Cl} + \text{CH}_3\text{O}_2$. The recommended value for $k(298 \text{ K})$ is based on results of Maricq et al.,³ Jungkamp et al.,² and Daële and Poulet.¹ All three studies agree that this overall reaction is very fast. However, there is a discrepancy in the reported values of the branching ratios for the two pathways producing $\text{ClO} + \text{CH}_3\text{O}$ (a) and $\text{HCl} + \text{CH}_2\text{O}_2$ (b). The branching ratio for the reaction channels producing $\text{HCl} + \text{CH}_2\text{O}_2$ (b) was

reported to be 50% by both Maricq et al. and Jungkamp et al. but was reported to be 90% by Daële and Poulet. Because of this large discrepancy no branching ratios are recommended.

F79. Cl + CH_3OH . This recommendation for $k(298\text{ K})$ is based on results of the absolute rate studies of Michael et al.,⁴ Payne et al.,⁷ Dobe et al.,¹ Pagsberg et al.,⁶ and Tyndall et al.,¹⁰ and results obtained in the competitive chlorination studies of Wallington et al.,¹¹ Lightfoot et al.,² Nelson et al.,⁵ and Tyndall et al. The temperature independence of the rate constant was reported by Michael et al. in a direct study. This is consistent with the indirect results of Lightfoot et al., who deduced the rate coefficient for this reaction relative to that for methane as a function of temperature. This reaction can have two sets of products: $\text{CH}_2\text{OH} + \text{HCl}$, channel (a) and $\text{CH}_3\text{O} + \text{HCl}$, channel (b). Product analysis and isotopic substitution have established that the reaction proceeds via channel (a) rather than via channel (b); see Radford,⁸ Radford et al.,⁹ Meier et al.,³ and Payne et al.⁷ This reaction has been used in the laboratory as a source of CH_2OH and as a source of HO_2 by the reaction of CH_2OH with O_2 .

F80. Cl + CH_3OOH . The recommended value for $k(298\text{ K})$ is taken from the only study of this reaction by Wallington et al.,¹ who measured the rate relative to $\text{Cl} + \text{C}_2\text{H}_6$ at 295 K and atmospheric pressure.

(Table: 02-25, Note: 02-25, Evaluated: 02-25) [Back to Table](#)

- (1) Wallington, T. J.; Andino, J. M.; Ball, J. C.; Japar, S. M. Fourier transform infrared studies of the reaction of Cl atoms with PAN, PPN, CH_3OOH , HCOOH , CH_3COCH_3 and $\text{CH}_3\text{COC}_2\text{H}_5$ at $295 \pm 2\text{ K}$. *J. Atmos. Chem.* **1990**, 10, 301-313.

F81. Cl + CH_3ONO_2 . This reaction has been studied at 298 K by Nielsen et al.¹ using a relative rate technique. The reference compound was ethane. The recommended value is adjusted from that given by Nielsen et al.

using the currently recommended value for $k(\text{Cl} + \text{C}_2\text{H}_6)$. The temperature dependence is estimated by assuming an A-factor equal to approximately 20 times that of $\text{OH} + \text{CH}_3\text{ONO}_2$. This is consistent with observed Cl/OH A-factor ratios for primary H-abstraction from alkanes.

(Table: 02-25, Note: 02-25, Evaluated: 02-25) [Back to Table](#)

- (1) Nielsen, O. J.; Sidebottom, H. W.; Donlon, M.; Treacy, J. An absolute- and relative-rate study of the gas phase reaction of OH radicals and Cl atoms with alkyl nitrates. *Chem. Phys. Lett.* **1991**, 178, 163-170.

F82. $\text{Cl} + \text{C}_2\text{H}_6$. The recommended value for $k(298\text{ K})$ is an average of the absolute rate coefficients reported in the studies of Manning and Kurylo,¹⁷ Lewis et al.,¹⁵ Dobis and Benson,⁶ Beichert et al.,³ Pilgrim et al.,¹⁹ Tyndall et al.,²⁴ Hitsuda et al.,⁹ Bryukov et al.,⁴ and Hickson and Keyser,⁸ all of which fall in the range $(5.3\text{--}6.1) \times 10^{-11} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$. The value derived by Ray et al.,²¹ in a study where the primary focus was not the determination of the rate constant for the target reaction, lies in the same range. A somewhat higher value reported by Davis et al.⁵ was probably overestimated by $\sim 10\%$ (the authors assumed that the fluorescence signal, I_f was proportional to $[\text{Cl}]^{0.9}$, whereas a linear relationship between I_f and $[\text{Cl}]$ probably held under their experimental conditions). The rate constant reported by Schlyer et al.²² lies significantly lower than those from all other absolute studies, while the values from Mellouki et al.¹⁸ and Kaiser et al.¹¹ lie slightly higher. Room temperature rate constants derived from the relative rate experiments of Pritchard et al.,²⁰ Knox and Nelson,¹³ Atkinson and Aschmann,¹ Atkinson and Ashmann,² Tschuikow-Roux et al.,²³ Wallington et al.,²⁵ Beichert et al.,³ Hooshiyar and Niki,¹⁰ and Lin et al.¹⁶ exhibit considerably more scatter even when recalculated based on the same (current) recommendations for the rate constants of the reference reactions. Nevertheless, most are encompassed within the 2σ uncertainty limits recommended for the value of $k(298\text{ K})$. The relative rate results of Kelly et al.¹² and Lee and Rowland¹⁴ are significantly lower than other room temperature measurements. The recommended value for E/R is taken from a combined fit to the data of Manning and Kurylo,¹⁷ Dobis and Benson,⁶ and Hickson and Keyser⁸ after scaling all three data sets to the recommended value of $k(298\text{ K})$. The data from Lewis et al.¹⁵ and Lin et al.¹⁶ below 300 K are encompassed by the 2σ uncertainty bands. The temperature dependent studies by Pilgrim et al.¹⁹ and Bryukov et al. did not extend below room temperature. An extrapolation of the recommended Arrhenius parameters and the 2σ uncertainty bands above room temperature encompasses the data of Pilgrim et al. but not those of Bryukov et al., which are characterized by a much stronger temperature dependence. The data obtained at very low temperatures (167–48 K) in Laval nozzle experiments by Hickson et al.⁷ strongly support the current recommendations.

F83. $\text{Cl} + \text{C}_2\text{H}_5\text{O}_2$. The recommended values of $k(298\text{ K})$ for the two reaction channels are based on results of Maricq et al.¹
(Table: 94-26, Note: 94-26, Evaluated: 94-26) [Back to Table](#)

- (1) Maricq, M. M.; Szente, J. J.; Kaiser, E. W.; Shi, J. Reaction of chlorine atoms with methylperoxy and ethylperoxy radicals. *J. Phys. Chem.* **1994**, *98*, 2083-2089, doi:10.1021/j100059a017.

F84. $\text{Cl} + \text{CH}_3\text{CH}_2\text{OH}$. The rate coefficient for this reaction has been studied at 298 K by four groups using a relative rate technique: Nelson et al.,² Wallington et al.,⁴ Edelbüttel-Einhaus et al.,¹ and Taatjes et al.³ Nelson et al. measured this rate constant relative to $\text{Cl} + \text{cyclohexane}$, while the others used $\text{Cl} + \text{C}_2\text{H}_6$ as the reference reaction. Taatjes et al. also measured this rate coefficient by measuring the temporal profile of the HCl product. The agreement between these five measurements is quite good, and the recommendation for $k(298\text{ K})$ is based on the average value. Taatjes et al. studied the temperature dependence of this rate coefficient above 298 K and found it to be essentially independent of temperature. We recommend the same temperature independence at atmospheric temperatures.

This reaction can have three sets of products: $\text{CH}_2\text{CH}_2\text{OH} + \text{HCl}$, channel (a); CH_3CHOH , channel (b); and $\text{CH}_3\text{CH}_2\text{O}$ channel (c). Taatjes et al. have deduced that channel (c) is negligible and that channel (a) is about 8% at 298 K. Therefore, the majority of reaction is expected to occur via channel (b). It is very unlikely that these branching ratios will change significantly at lower atmospheric temperatures.

F85. Cl + CH₃C(O)OH. The recommended value for k(298 K) is based on the room temperature study by Koch and Moortgat¹ using a relative rate technique. Deuterium substitution of the methyl hydrogens decreased the observed rate by a factor of 3.75. In addition, CO and CO₂ reaction products were observed in a stoichiometric ratio of 1:1. These observations were interpreted in terms of methyl hydrogen abstraction from acetic acid to form the CH₂C(O)OH radical followed by reaction with O₂ to form a peroxy radical. Thermal decomposition of the peroxy radical produces HCHO, CO₂, and atomic H. In the laboratory system, the HCHO reacts with atomic chlorine to yield CO.

- (4) Tyndall, G. S.; Orlando, J. J.; Wallington, T. J.; Sehested, J.; Nielsen, O. J. Kinetics of the reactions of acetonitrile with chlorine and fluorine atoms. *J. Phys. Chem.* **1996**, *100*, 660-668, doi:10.1021/jp9521417.

F87. Cl + C₂H₅ONO₂. Wallington et al.² and Nielsen et al.¹ have measured the rate of this reaction at room temperature relative to atomic chlorine reactions with ethyl chloride and ethane, respectively. The two studies are in excellent agreement, and the recommended value is based on an average of the two. The values given in Wallington et al. and Nielsen et al. were adjusted based on the currently accepted values of the reference rate constants. The temperature dependence is estimated by assuming an A-factor equal to approximately 20 times that of OH + CH₃ONO₂. This is consistent with observed Cl/OH A-factor ratios for primary H-abstraction from alkanes.

- (1) Nielsen, O. J.; Sidebottom, H. W.; Donlon, M.; Treacy, J. An absolute- and relative-rate study of the gas phase reaction of OH radicals and Cl atoms with alkyl nitrates. *Chem. Phys. Lett.* **1991**, *178*, 163-170.
- (2) Wallington, T. J.; Hinman, M. M.; Andino, J. M.; Siegl, W. O.; Japar, S. M. A relative rate study of the reaction of Cl atoms with a series of alkyl nitrates and nitro alkanes in air at 295 ± 2K. *Int. J. Chem. Kinet.* **1990**, *22*, 665-671.

F88. Cl + CH₃CO₃NO₂ (PAN). The recommended upper limit for k(298 K) is based on results of the relative rate study of Wallington et al.² In this study, no reaction of PAN was observed in the presence of Cl atoms. These results are preferred over the results of the direct study of Tsalkani et al.¹ using a discharge flow system with EPR detection of Cl atom decay (in which the authors reported a rate constant of $(3.7 \pm 1.7) \times 10^{-13} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$). In both studies, the major impurity in the PAN samples would be the alkane solvent. The presence of 0.1% tridecane in the PAN sample used by Tsalkani et al. could account for the observed Cl atom

decay; however, solvent impurities in the PAN sample would be of no consequence in the relative rate study of Wallington et al.

(Table: 92-20, Note: 92-20, Evaluated: 92-20) [Back to Table](#)

- (1) Tsalkani, N.; Mellouki, A.; Poulet, G.; Toupance, G.; Le Bras, G. Rate constant measurement for the reactions of OH and Cl with peroxyacetyl nitrate at 298 K. *J. Atmos. Chem.* **1988**, 7, 409-419.
- (2) Wallington, T. J.; Andino, J. M.; Ball, J. C.; Japar, S. M. Fourier transform infrared studies of the reaction of Cl atoms with PAN, PPN, CH₃OOH, HCOOH, CH₃COCH₃ and CH₃COC₂H₅ at 295 ± 2 K. *J. Atmos. Chem.* **1990**, 10, 301-313.

F89. Cl + C₃H₈. The recommended values for k(298 K) and E/R for two individual reaction channels are presented in the Table. The recommended k(298 K) values are the means of the results from the competitive chlorination studies by Knox and Nelson,⁸ Kelly et al.,⁷ Tschuikow-Roux et al.,¹⁴ Tyndall et al.,¹⁵ and Sarzynski and Sztuba.¹³ The recommended E/R values are based on the data of Sarzynski and Sztuba obtained between 300 K and 400 K.

The recommended value for k(298 K) for the overall reaction given below is the mean of results of the competitive chlorination studies of Pritchard et al.,¹² Knox and Nelson,⁸ Kelly et al.,⁷ Tschuikow-Roux et al.,¹⁴ Atkinson and Aschmann,¹ Wallington et al.,¹⁶ Beichert et al.,² Hooshiyar and Niki,⁶ Tyndall et al.¹⁵ (two determinations), and Sarzynski and Sztuba,¹³ and the absolute rate studies of Lewis et al.,⁹ Beichert et al.,² Pilgrim et al.,¹¹ Mellouki,¹⁰ Hitsuda et al.⁵, and Choi et al.³ The recommended value of E/R = 0 for the overall reaction is based on the data obtained between 300 K and 400 K by Sarzynski and Sztuba. The data obtained at very low temperatures (167 K–48 K) in Laval nozzle experiments by Hickson et al.,⁴ the data of Pilgrim et al.,¹¹ extended to higher temperatures (292 K – 700 K), and the measurements by Choi et al.³ at 298 K and 195 K exhibit no variation with temperature and, thus, support this recommendation.

$$\begin{aligned} A &= 1.45 \times 10^{-10} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1} \\ E/R &= 0 \\ k(298 \text{ K}) &= 1.4 \times 10^{-10} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1} \\ f(298 \text{ K}) &= 1.05 \\ g &= 0 \end{aligned}$$

The sum of the recommended rate constant expressions for the two channels gives the same values as the rate constant expression recommended for the total reaction.

F90. Cl + CH₃C(O)CH₃. The recommended value for k(298 K) is an average of the values derived in the relative rate studies by Carr et al.,² Christensen et al.,³ Martinez et al.,⁴ Orlando et al.,⁷ Romanias et al.,⁸ and Wallington et al.¹⁰ and in the absolute rate studies by Romanias et al.,⁸ Takahashi et al.,⁹ and Zhao et al.,¹¹ all of which agree to within 15–20%. Room temperature rate constants reported by Notario et al.⁵ and Albaladejo et al.¹ are about 40–50% greater than the recommended value, whereas the value reported by Olsson et al.⁶ is approximately 25% lower than recommended. Because of the level of disagreement with eight other studies, the results of the last three investigations listed above were not included in deriving the recommended value for k(298 K). The recommended value for E/R is derived from an Arrhenius fit to the data of Orlando et al.⁷ and Zhao et al.¹¹ and the absolute rate data of Romanias et al.⁸ after scaling each data set to the recommended value for k(298 K). The relative rate data from Romanias et al. were not included due to uncertainties in the rate constants for the reference reactions. Nevertheless, the rate constant values derived from these relative rate experiments are in good agreement with the recommended rate expression. Although the data of Orlando et al.⁷ lie systematically about 13% lower than those of Zhao et al.,¹¹ the E/R values reported in both studies are nearly identical. End product studies clearly show that the products of this reaction are CH₃C(O)CH₂ and HCl.

F91. $\text{Cl} + \text{CH}_2=\text{C}(\text{CH}_3)\text{CHO}$ (Methacrolein). The recommendation is based on the relative rate studies of Kaiser et al.⁴ and Orlando et al.⁵ with the error limits adjusted to encompass the results of Canosa-Mas et al.^{1,2} and Wang et al.⁷ Kaiser et al. report that the 297 K rate coefficient is pressure dependent at $P < 100$ Torr N_2 , a result that is confirmed theoretically by Sun et al.,⁶ who also calculate a 297 K high pressure limit rate constant in excellent agreement with the recommendation. The available information suggests that the rate constant measured by Canosa-Mas et al. in a low-pressure discharge flow study¹ is too fast. Experimental yields of HCl are reported by Canosa-Mas et al.¹ ($18 \pm 2\%$) and Kaiser et al. ($27 \pm 3\%$). Additional product studies by Kaiser et al. lead these authors to conclude that $\sim 90\%$ of the HCl production is via abstraction of the aldehydic hydrogen with the other 10% being attributable to abstraction of a methyl hydrogen. Sun et al. obtain a theoretical HCl yield of 12% with essentially all HCl production resulting from abstraction of the aldehydic hydrogen. Molar yields of carbon-containing products in NO_x -free air at $P \sim 1$ atm and $T \sim 297$ K have been reported by Kaiser et al. ($44 \pm 5\%$ $\text{ClCH}_2\text{C}(\text{O})\text{CH}_3$; $27 \pm 3\%$ CO_2 ; $14 \pm 2\%$ HCHO) and Orlando et al. ($52 \pm 4\%$ CO ; $42 \pm 5\%$ $\text{ClCH}_2\text{C}(\text{O})\text{CH}_3$; $23 \pm 2\%$ CO ; $18 \pm 2\%$ HCHO ; $\sim 5\%$ ClCHO); the significant yield of $\text{ClCH}_2\text{C}(\text{O})\text{CH}_3$ suggests that addition of Cl to the terminal carbon of the double bond is an important reaction pathway. A turbulent flow reactor study by Hsin and Elrod³ obtains a Cl-methacrolein-OO + NO rate constant of $(1.17 \pm 0.11) \times 10^{-11} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$.

F92. $\text{Cl} + \text{CH}_3\text{C}(\text{O})\text{CH}=\text{CH}_2$ (MVK). The recommendation is based on the relative rate studies of Canosa-Mas et al.,² Finlayson-Pitts et al.,³ Orlando et al.,⁵ and Wang et al.,⁶ all of which were carried out at room temperature using ~ 1 atm N_2 ^{2,3,6} or air⁵ bath gas. In a low-pressure flow tube study, Canosa-Mas et al.¹ obtain rate constants that are about a factor of two slower than the recommended value. Product yields reported by Orlando et al. in NO_x -free air at $P = 1$ atm and $T = 298$ K are 75% ClCH_2CHO , $58 \pm 5\%$ CO_2 , $47 \pm 7\%$ HCHO , 8% CH_3OH , $7 \pm 1\%$ ClCHO , and 6% $\text{CH}_3\text{C}(\text{O})\text{OOH}$; the large observed yield of ClCH_2CHO leads to the conclusion that the dominant reaction pathway is addition to the terminal carbon atom of the double bond. A turbulent flow reactor study by Hsin and Elrod⁴ obtains a Cl-MVK-OO + NO rate constant of $(1.14 \pm 0.14) \times 10^{-11} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$.

- (6) Wang, W.; Ezell, M. J.; Ezell, A. A.; Soskin, G.; Finlayson-Pitts, B. J. Rate constants for the reactions of chlorine atoms with a series of unsaturated aldehydes and ketones at 298 K: structure and reactivity. *Phys. Chem. Chem. Phys.* **2002**, *4*, 1824-1831, doi:10.1039/b111557j.

F93. $\text{Cl} + \text{CH}_2=\text{C}(\text{CH}_3)\text{CH}=\text{CH}_2$ (Isoprene). The recommended 298 K rate constant is an average of room temperature results reported by Ragains and Finlayson-Pitts,¹⁰ Fantechi et al.,⁴ Notario et al.,^{4,7} Bedjanian et al.,² Stutz et al.,¹¹ Finlayson-Pitts et al.,⁵ Canosa-Mas et al.,³ Suh and Zhang,¹² Albaladejo,¹ Orlando et al.,⁸ and Xing et al.¹³ The recommended E/R is based on the single temperature dependence study by Bedjanian et al.,² which covered the range 233–320 K. Although the atmospheric pressure relative rate studies of Ragains and Finlayson-Pitts, Fantechi et al., Finlayson-Pitts et al., and Canosa-Mas et al. suggest a 298 K rate constant that is nearly 20% faster than the recommended value, Bedjanian et al. report little or no pressure dependence over the range 0.25–3.0 Torr He, and Xing et al. report no pressure dependence at pressures above 1 Torr Ar. A recommended temperature-dependent yield for HCl is given by the expression $1.1 \exp(-595/T)$; the temperature dependence is that reported by Bedjanian et al. while the pre-exponential factor is adjusted to give a 298 K yield of 0.15, the average of values reported by Bedjanian et al., Ragains and Finlayson-Pitts, Fantechi et al., Suh and Zhang, and Xing et al. The reported 298 K HCl yields are in excellent agreement even though they were obtained under very different conditions of pressure and bath gas, i.e., 1 Torr He,² 10 Torr He,¹² 700 Torr N_2 ,¹³ 740 Torr Air,⁴ and 760 Torr N_2 .¹⁰ Molar yields of carbon-containing products in NO_x -free air at $P \sim 1$ atm and $T \sim 297$ K have been reported by Nordmeyer et al.⁶ ($9 \pm 5\%$ $\text{CH}_3\text{C}(\text{O})\text{CH}=\text{CH}_2$; unquantified but significant yields of $\text{ClCH}_2\text{C}(\text{O})\text{C}(\text{CH}_3)=\text{CH}_2$ and its isomers), Fantechi et al. ($4.4 \pm 3.3\%$ ClCHO ; $1.1 \pm 0.8\%$ HCOOH ; $25.7 \pm 7.4\%$ CO), and Orlando et al. ($9.5 \pm 1.0\%$ HCHO ; $5.1 \pm 0.7\%$ ClCHO ; unquantified amount of $\text{ClCH}_2\text{C}(\text{O})\text{C}(\text{CH}_3)=\text{CH}_2$). A turbulent flow reactor study by Patchen et al.⁹ obtains a Cl-isoprene-OO + NO rate constant of $(1.15 \pm 0.11) \times 10^{-11} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ (there are six isomers of Cl-isoprene-OO that could be generated, but the distribution in the Patchen et al. study is presumably the same as would be formed in the atmosphere).

Kinetics of the reaction of chlorine atoms with isoprene (2-methyl 1,3-butadiene, $\text{CH}_2=\text{C}(\text{CH}_3)\text{CH}=\text{CH}_2$) at 297 ± 2 K. *Chem. Phys. Lett.* **2009**, *472*, 39-43, doi:10.1016/j.cplett.2009.03.002.
- F94. $\text{Cl} + \text{C}_2\text{H}_5\text{CO}_3\text{NO}_2$.** Wallington et al.¹ have measured this rate constant relative to $\text{Cl} + \text{CH}_3\text{Cl}$. The recommended value of $k(298 \text{ K})$ is adjusted from that given by Wallington et al. using the currently recommended value for the reference reaction rate constant.
(Table: 02-25, Note: 02-25, Evaluated: 02-25) [Back to Table](#)
- (1) Wallington, T. J.; Andino, J. M.; Ball, J. C.; Japar, S. M. Fourier transform infrared studies of the reaction of Cl atoms with PAN, PPN, CH_3OOH , HCOOH , CH_3COCH_3 and $\text{CH}_3\text{COC}_2\text{H}_5$ at 295 ± 2 K. *J. Atmos. Chem.* **1990**, *10*, 301-313.
- F95. $\text{Cl} + 1\text{-C}_3\text{H}_7\text{ONO}_2$.** The recommended value of $k(298 \text{ K})$ is based on studies by Wallington et al.² and Nielsen et al.,¹ who measured the rate constant at room temperature relative to atomic chlorine reactions with ethyl chloride and ethane, respectively. The two studies are in excellent agreement, and the recommended value is based on an average of the two.
(Table: 10-6, Note: 10-6), Evaluated: 10-6) [Back to Table](#)

- F98. $\text{Cl} + \text{ClOO}$.** The recommended Arrhenius parameters are based on the studies by Mauldin et al.⁵ and Baer et al.,² in which ClOO was formed by the pulsed photolysis of Cl_2/O_2 mixtures and its overall loss rate was monitored by UV absorption. In both studies k was found to be independent of temperature. These results are preferred over the results of the earlier, indirect studies of Johnston et al.,⁴ Cox et al.,³ and Ashford et al.¹ The earlier studies did show that the predominant reaction pathway is that yielding $\text{Cl}_2 + \text{O}_2$ as products. From the branching ratio data of Cox et al., Ashford et al., and Nicholas and Norrish,⁶ it can be estimated that

this reaction channel constitutes 95% of the overall reaction with ClO + ClO the products of the minor (5%) reaction channel.

F99. Cl + Cl₂O. The recommended parameters are determined from results of the temperature-dependent study of Stevens and Anderson⁴ and the results of two independent absolute rate coefficient studies reported by Ray et al.,³ which used the discharge flow-resonance fluorescence and discharge flow-mass spectrometric techniques. The recommended value for $k(298\text{ K})$ is in agreement with the results of Burrows and Cox,² who determined the ratio $k(\text{Cl} + \text{Cl}_2\text{O})/k(\text{Cl} + \text{H}_2) = 6900$ in modulated photolysis experiments. The earlier value reported by Basco and Dogra¹ has been rejected.

Phys. Chem.* **1992**, *96*, 1708-1718, doi:10.1021/j100183a040.

F100. Cl + Cl₂O₂. The recommended Arrhenius parameters are from Ingham et al.² in a study between 217 K and 298 K using a DF-MS/RF technique. The room temperature value reported by Cox and Hayman¹ in a study using a static photolysis technique with photodiode array UV spectroscopy is in excellent agreement with the recommended value.

F101. Cl + HOCl. The recommended parameters are based on results over the temperature range 243–365 K reported by Cook et al.¹ and the room temperature result of Kukui et al.³ The earlier work of Vogt and Schindler⁴ is thought to have been plagued by complexities with the F-atom titration procedure used for HOCl calibration. Ennis and Birks² and Kukui et al. reported that the major reaction channel gives the products $\text{Cl}_2 + \text{OH}$ with measured yields of $91 \pm 6\%$ and $96 \pm 5\%$, respectively. Theoretical calculations by Wang et al.⁵ lend support to the predominance of the $\text{Cl}_2 + \text{OH}$ channel at all temperatures below 300 K.

F102. Cl + ClNO. The recommended value for $k(298\text{ K})$ is the mean of the values reported by Abbatt et al.,¹ Chasovnikov et al.,² Nesbitt et al.,⁸ and Kita and Stedman.⁶ The room temperature result of Chesnokov³ is in fair agreement with the recommended value. The laser photolysis-LMR study of Chasovnikov et al.² provides rate data for each Cl atom spin state, and they attribute the low value reported by Nelson and Johnston⁷ in a laser flash photolysis-resonance fluorescence study to reaction of the $\text{Cl } ^2\text{P}_{1/2}$ state. Adsorption and decomposition of ClNO on the walls of their static system may account for the very low value of Grimley and Houston.⁵ The results of Clyne and Cruse⁴ in a discharge flow-resonance fluorescence study are significantly lower than all of the later studies. The recommended Arrhenius parameters are from the study of Abbatt et al.¹

F103. Cl + ClONO₂. The recommended Arrhenius parameters are based on the results of Yokelson et al.³ and those of Margitan², which are in excellent agreement. The slightly higher values of Kurylo et al.¹ lie just outside the stated uncertainties. Yokelson et al. report that at 298 K, more than 95% of this reaction proceeds by the reaction channel giving $\text{Cl}_2 + \text{NO}_3$ as products.

(Table: 10-6, Note: 10-6, Evaluated: 10-6) [Back to Table](#)

- (1) Kurylo, M. J.; Knable, G. L.; Murphy, J. L. A reinvestigation of the $\text{Cl} + \text{ClONO}_2$ reaction by flash photolysis resonance fluorescence. *Chem. Phys. Lett.* **1983**, 95, 9-12.
- (2) Margitan, J. J. Chlorine nitrate photochemistry. Photolysis products and kinetics of the reaction $\text{Cl} + \text{ClONO}_2 \rightarrow \text{Cl}_2 + \text{NO}_3$. *J. Phys. Chem.* **1983**, 87, 674-679, doi:10.1021/j100227a029.
- (3) Yokelson, R. J.; Burkholder, J. B.; Goldfarb, L.; Fox, R. W.; Gilles, M. K.; Ravishankara, A. R. Temperature dependent rate coefficient for the $\text{Cl} + \text{ClONO}_2$ reaction. *J. Phys. Chem.* **1995**, 99, 13976-13983.

F104. Cl + CH₃Cl. The recommended value for $k(298\text{ K})$ is the mean of results of the absolute rate studies of Manning and Kurylo,⁶ Beichert et al.,¹ and Bryukov et al.² and the relative rate studies of Wallington et al.,¹¹ Beichert et al.,¹ Orlando⁷ (two independent determinations), and Sarzyński et al.⁹ The recommended E/R is derived from a fit to the data below 300 K from Manning and Kurylo⁶ and from the two relative rate studies of Orlando⁷ after scaling each data set to the recommended value for $k(298\text{ K})$. While the 298 K results reported by Clyne and Walker³ are in good agreement, the value of the activation energy derived by these researchers is significantly higher than that recommended, similar to the situation encountered for the Cl + CH₄ reaction. Hence, it is assumed that the discharge flow-mass spectrometric studies of these authors were subject to a systematic error. The E/R obtained between 300 K and 400 K by Bryukov et al.,² from a study primarily focused at higher temperatures, is in good agreement with that recommended here. The early relative rate studies by Pritchard et al.,⁸ Goldfinger et al.,⁴ Knox,⁵ and Tschuikow-Roux et al.,¹⁰ were not used to derive the recommended parameters since they were performed at temperatures above 298 K and, with the exception of Pritchard et al., yield somewhat higher values for E/R .

F105. Cl + CH₂Cl₂. The recommended value for $k(298\text{ K})$ is an average of the values measured in the relative rate studies of Niki et al.,⁷ Beichert et al.,¹ Catoire et al.,³ and Orlando⁸ (two independent determinations), and in the absolute rate study of Bryukov et al.² For this evaluation, all of the relative rate measurements were recalculated based on the current recommendations for the rate constant of the reference reactions. The recommended value for E/R is derived from the data of Orlando and agrees with a fit to the data of Bryukov et al. (obtained at room temperature and above) up to 400 K. Above 400 K, these latter data increase more rapidly with temperature. The relative rate studies of Goldfinger et al.,⁵ Knox,⁶ and Tschuikow-Roux et al.⁹ were performed at temperatures above 298 K and yield significantly higher values for E/R , with the exception of one of the Knox et al. determinations (relative to CH₄), which gives a value of E/R in good agreement with that recommended. The results of Clyne and Walker⁴ are higher than those from any other study and were not used in deriving the recommended parameters.

F106. Cl + CHCl_3 . The recommended value for $k(298\text{ K})$ is an average of the values measured in the relative rate studies of Beichert et al.,¹ Brahan et al.² (two independent determinations), Catoire et al.,⁴ and Orlando⁹ (two independent determinations). The recommended temperature dependence is derived from a fit to the two determinations by Orlando and agrees with a fit to the absolute rate data of Bryukov et al.³ (obtained at room temperature and above) up to 400 K. Above 400 K, these latter data increase more rapidly with temperature. The room temperature value determined in the relative rate study by Yu and Wijnen¹¹ is a factor of 50 greater than recommended and was not considered in the recommendation. The results of the absolute investigation of Clyne and Walker⁵ are also higher and more scattered than those from most other studies and were not used, nor was the room temperature value derived from the study by Jeoung et al.,⁷ which is more than a factor of two lower than recommended. The relative rate study by Goldfinger et al.⁶ performed near 500 K obtained values higher than those in more recent investigations. The relative rate study of Knox⁸ yields a similar temperature dependence to that recommended but with rate constant values systematically lower than other studies. The absolute study by Talhaoui et al.¹⁰ yielded a 298 K rate constant somewhat lower than recommended and a temperature dependence somewhat higher. For this evaluation, all of the relative rate measurements were recalculated based on the current recommendations for the rate constant of the reference reactions.

F107. Cl + CH₃F (HFC-41). The recommended value for $k(298\text{ K})$ is an average of the values from the absolute rate studies of Manning and Kurylo² and Hitsuda et al.¹ and the relative rate studies of Tschuikow-Roux et al.,³ Tuazon et al.,⁴ and Wallington et al.⁵ The recommended value for E/R is based on the study of Tschuikow-Roux et al. conducted at room temperature and above. However, in formulating this recommendation for E/R, the reported temperature dependence of Tschuikow-Roux et al. was reduced slightly (by approximately 100 K) to account for what appears to be a small systematic difference between the activation energies obtained in their similar investigations of the Cl + CH₃Cl and Cl + CH₃Br reactions above room temperature and the recommendations that are based on data at 300 K and below. The temperature dependence reported by Manning and Kurylo is significantly lower, seemingly due to a shift in their data below 250 K. This lower value of E/R is not consistent with the recommended values of E/R for Cl + CH₃Cl and Cl + CH₃Br when compared with those for OH + CH₃F, OH + CH₃Cl, and OH + CH₃Br. Hence, it appears that the Manning and Kurylo data may have been influenced by some systematic error at the lower temperatures.

F108. Cl + CH₂F₂ (HFC-32). The recommended value for $k(298\text{ K})$ is an average of the values from the relative rate study of Nielsen et al.¹ and from an Arrhenius fit to the relative rate data of Nilsson et al.² obtained in two independent studies, all recalculated using the rate constant for the reference reaction (Cl + CH₄) recommended in this evaluation. The recommended value for E/R is obtained from a fit to the data of Nilsson et al.² below 410 K. The rate constants determined in the relative rate study of Tschuikow-Roux et al.³ lie systematically higher than those of Nielsen et al.¹ and Nilsson et al.² but yield a temperature dependence similar to that recommended here.

F109. Cl + CHF₃ (HFC-23). The recommended upper limit for $k(298\text{ K})$ is based on results from the absolute rate study by Jourdain et al.² Results from the relative rate study by Coomber and Whittle¹ yield an upper limit that is a factor of 50 smaller.

F110. Cl + CH₂FCI (HCFC-31). The recommended value for k(298 K) is an average of the room temperature results from the absolute rate study by Jourdain et al.¹ and the relative rate studies by Tuazon et al.³ and Wallington et al.⁴ The temperature dependence is estimated from a comparison among the Cl and OH reactions with CH₂F₂, CH₂Cl₂, and CH₂FCI. The recommended value of E/R (essentially the same as that for the OH + CH₂FCI reaction) is slightly lower than that determined by Tschuikow-Roux et al.,² recalculated based on the current recommendation for the rate constant of the reference reaction (Cl + CH₄). However, as discussed for other Cl + halomethane reactions, there appears to be a small systematic overestimation in the temperature dependences determined by these authors.

F111. Cl + CHFCl₂ (HCFC-21). The recommended value for k(298 K) is the average of the results from the relative rate study of Tuazon et al.⁴ and the absolute rate study of Talhaoui et al.³ These results are preferred over the earlier room temperature results of Glavas and Heicklen.¹ The room temperature value of Jourdain et al.² is approximately 50% higher than the recommendation. The recommended value for E/R is derived from the data of Talhaoui et al.

F112. Cl + CHF₂Cl (HCFC-22). The recommended value for k(298 K) is the mean of the values derived in the relative rate studies of Tuazon et al.⁵ and Sokolov et al.³ and in the absolute rate studies of Jourdain et al.¹ and Talhaoui et al.⁴ (which is assumed to supersede the earlier study by Sawerysyn et al.²). The recommended E/R is derived from the data reported by Talhaoui et al.

F113. $\text{Cl} + \text{CH}_3\text{CCl}_3$. The recommended value for $k(298 \text{ K})$ is an average of the results from the absolute rate study by Talhaoui et al.⁴ and the relative rate studies of Platz et al.³ and Nilsson et al.,² both recalculated using the rate constant for the reference reaction ($\text{Cl} + \text{CH}_4$) recommended in this evaluation. The recommended value for E/R is derived from a combined fit to the data of Talhaoui et al.⁴ and Nilsson et al.² for $T < 400 \text{ K}$ after scaling each data set to the recommended value for $k(298 \text{ K})$. The results obtained by Cillien et al.¹ in a relative rate study conducted over a very narrow temperature range above room temperature are encompassed by the recommended 2σ uncertainty. The results of the relative rate study of Tschuikow-Roux et al.,⁵ although exhibiting a similar temperature dependence, lie systematically higher than the results of all other investigations.

F114. $\text{Cl} + \text{CH}_3\text{CH}_2\text{F}$ (HFC-161). The recommended values for both $k(298 \text{ K})$ and E/R for each of the two reaction channels are averages of the individual values derived in the relative rate studies of Cadman et al.,¹ Martens et al.,³ and Tschuikow-Roux et al.,⁴ with each recalculated based on the current recommendation for the rate constant of the reference reaction. The value for $k(298 \text{ K})$ of the total reaction obtained from a sum of the two channels is in excellent agreement with the value obtained in the absolute rate study by Hitsuda et al.² The parameters for the total reaction are:

$$\begin{aligned} A &= 2.28 \times 10^{-11} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1} \\ E/R &= 370 \text{ K} \\ k(298 \text{ K}) &= 6.6 \times 10^{-12} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1} \\ f(298 \text{ K}) &= 1.1 \\ g &= 100 \end{aligned}$$

(Table: 06-2, Note: 06-2, Evaluated: 06-2) [Back to Table](#)

- (2) Hitsuda, K.; Takahashi, K.; Matsumi, Y.; Wallington, T. J. Kinetics of the reactions of $\text{Cl}(^2\text{P}_{1/2})$ and $\text{Cl}(^2\text{P}_{3/2})$ atoms with C_2H_6 , C_2D_6 , CH_3F , $\text{C}_2\text{H}_5\text{F}$, and CH_3CF_3 at 298 K. *J. Phys. Chem. A* **2001**, *105*, 5131-5136, doi:10.1021/jp003222s.
- (3) Martens, G. J.; Godfroid, M.; Delvaux, J.; Verbeyst, J. Gas-phase hydrogen abstraction from asymmetrically halogenated ethanes by chlorine atoms. *Int. J. Chem. Kinet.* **1976**, *8*, 153-158.
- (4) Tschuikow-Roux, E.; Yano, T.; Niedzielski, J. Reactions of ground state chlorine atoms with fluorinated methanes and ethanes. *J. Chem. Phys.* **1985**, *82*, 65-74.

F115. $\text{Cl} + \text{CH}_3\text{CHF}_2$ (HFC-152a). The recommended values for $k(298 \text{ K})$ for each of the two reaction channels are based on an average of the individual values from the relative rate studies of Cadman et al.,¹ Martens et

al.,² and Yano and Tschuikow-Roux⁶ (with each recalculated based on the current recommendation for the rate constant of the appropriate reference reaction). The sum of these average values of $k(298\text{ K})$ for the two channels is $2.4 \times 10^{-13}\text{ cm}^3\text{ molecule}^{-1}\text{ s}^{-1}$. However, a more reliable value for $k(298\text{ K}) = 2.5 \times 10^{-13}\text{ cm}^3\text{ molecule}^{-1}\text{ s}^{-1}$ for the overall reaction can be obtained from an average of the results from the relative rate studies of Wallington and Hurley,⁵ Tuazon et al.,⁴ and Taketani et al.³ and from the absolute study of Taketani et al.³ Therefore, for consistency with the total rate constant recommendation, $k(298\text{ K})$ for each channel was scaled by a factor 1.04 (i.e., $2.5/2.4$) to obtain the recommended values given in Table 1. The recommended value for E/R for each channel is an average of those determined by Cadman et al.,¹ Martens et al.,² and Yano and Tschuikow-Roux.⁶ There are no available experimental data on the temperature dependence of the rate constant of the total reaction. A simulated fit to the sum of the rate constants recommended for individual channels yields $E/R = 970\text{ K}$, which is recommended here. Thus, the recommended parameters for the total reaction are:

$$\begin{aligned} A &= 6.5 \times 10^{-12}\text{ cm}^3\text{ molecule}^{-1}\text{ s}^{-1} \\ E/R &= 970\text{ K} \\ k(298\text{ K}) &= 2.5 \times 10^{-13}\text{ cm}^3\text{ molecule}^{-1}\text{ s}^{-1} \\ f(298\text{ K}) &= 1.1 \\ g &= 100 \end{aligned}$$

F116. Cl + $\text{CH}_2\text{FCH}_2\text{F}$ (HFC-152). The recommended value for $k(298\text{ K})$ is an average of the values derived in the relative rate studies of Yano and Tschuikow-Roux² and Wallington et al.¹ (two determinations), after recalculating each one based on the current recommendation for the rate constant of the appropriate reference reaction. The recommended temperature dependence was determined from a fit to the data of Yano and Tschuikow-Roux, which were obtained at room temperature and above. The temperature dependence may exhibit curvature below room temperature, similar to that for $\text{OH} + \text{CH}_2\text{FCH}_2\text{F}$. Such curvature is most probably encompassed by the assigned uncertainty parameters.

(Table: 06-2, Note: 06-2, Evaluated: 06-2) [Back to Table](#)

- (1) Wallington, T. J.; Hurley, M. D.; Schneider, W. F.; Sehested, J.; Nielsen, O. J. Mechanistic study of the gas-phase reaction of CH_2FO_2 radicals with HO_2 . *Chem. Phys. Lett.* **1994**, 218, 34-42.

F117. Cl + CH_3CFCl_2 (HCFC-141b). The recommended value for $k(298\text{ K})$ is an average of the values derived in the absolute rate studies of Talhaoui et al.² and Warren and Ravishankara⁵ and in the relative rate studies of Wallington and Hurley⁴ and Tuazon et al.³ The room temperature results of Talhaoui et al. are assumed to supersede those of Sawerysyn et al.¹ The recommended E/R is derived from the data of Talhaoui et al. The data of Warren and Ravishankara⁵ above room temperature exhibit considerable scatter, apparently due to Cl atom regeneration from decomposition of the radical product ($\text{CH}_2\text{-CFCl}_2$). Hence, this study was not used in deriving the recommended temperature dependence.

F120. $\text{Cl} + \text{CH}_2\text{FCHF}_2$ (HFC-143). The recommended values for $k(298\text{ K})$ and E/R for each of the two reaction channels are based on results of the relative rate study of Tschuikow-Roux et al.,¹ recalculated based on the current recommendation for the rate constant of the reference reaction ($\text{Cl} + \text{CH}_4$). The recommended

parameters for the total reaction are derived from the sum of the recommended rate expressions for the two reaction channels. The parameters for the total reaction are:

$$A = 1.57 \times 10^{-11} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$$

$$E/R = 1720 \text{ K}$$

$$k(298 \text{ K}) = 4.9 \times 10^{-14}$$

$$f(298 \text{ K}) = 1.3$$

$$g = 200$$

- (3) Warren, R. F.; Ravishankara, A. R. Kinetics of $\text{Cl}(^2\text{P})$ reactions with CF_3CHCl_2 , CF_3CHFCl , and CH_3CFCl_2 . *Int. J. Chem. Kinet.* **1993**, 25, 833-844.

F125. $\text{Cl} + \text{CHFClCF}_3$ (HCFC-124). The recommended value for $k(298\text{ K})$ is an average of the results from the absolute rate study by Warren and Ravishankara² and the relative rate study by Tuazon et al.¹ The recommended value for E/R is derived from the data of Warren and Ravishankara. (Table: 06-2, Note: 06-2, Evaluated: 06-2) [Back to Table](#)

- (1) Tuazon, E. C.; Atkinson, R.; Corchnoy, S. B. Rate constants for the gas-phase reactions of Cl atoms with a series of hydrofluorocarbons and hydrochlorofluorocarbons at $298 \pm 2\text{ K}$. *Int. J. Chem. Kinet.* **1992**, 24, 639-648.
- (2) Warren, R. F.; Ravishankara, A. R. Kinetics of $\text{Cl}(^2\text{P})$ reactions with CF_3CHCl_2 , CF_3CHFCl , and CH_3CFCl_2 . *Int. J. Chem. Kinet.* **1993**, 25, 833-844.

F126. $\text{Cl} + \text{CHF}_2\text{CF}_3$ (HFC-125). The recommended value for $k(298\text{ K})$ is an average of the results from the relative rate studies of Tuazon et al.,⁴ Sehested et al.,³ Edney and Driscoll,² and Young et al.,⁵ all conducted only at room temperature and recalculated using the current recommendations for the rate constants of the reference reactions. The temperature dependence is estimated from a comparison among the Cl and OH reactions with CH_2FCF_3 , CHF_2CHF_2 , and CHF_2CF_3 . The relative rate study by Coomber and Whittle¹ conducted between 303 K and 399 K corresponds to a value for $k(298\text{ K})$ a factor of 2.5 greater than that recommended. However, the value for E/R derived by these authors is only slightly lower than that estimated.

Atmospheric chemistry of $\text{CF}_3\text{CF}_2\text{H}$ and $\text{CF}_3\text{CF}_2\text{CF}_2\text{CF}_2\text{H}$: Kinetics and products of gas-phase reactions with Cl atoms and OH radicals, infrared spectra, and formation of perfluorocarboxylic acids. *Chem. Phys. Lett.* **2009**, 473, 251-256, doi:10.1016/j.cplett.2009.04.001.

F127. $\text{ClO} + \text{O}_3$. There are two possible channels for this reaction: $\text{ClO} + \text{O}_3 \rightarrow \text{ClOO} + \text{O}_2$ (k_1); and $\text{ClO} + \text{O}_3 \rightarrow \text{OCIO} + \text{O}_2$ (k_2). The recommended upper limit for k_1 at 298 K is based on results of Stevens and Anderson.² These authors also report that $k_1 = (4 \pm 2) \times 10^{-16} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ at 413 K. These data can be combined to derive the recommended Arrhenius parameters, $A = 2 \times 10^{-12} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ and $E/R > 3600\text{ K}$. The

upper limit for k_2 is based on results reported by DeMore et al.¹ and Wongdontri-Stuper et al.³ The Arrhenius parameters for k_2 were estimated.

(Table: 92-20, Note: 92-20, Evaluated: 10-6) [Back to Table](#)

- (3) Wongdontri-Stuper, W.; Jayanty, R. K. M.; Simonaitis, R.; Heicklen, J. The Cl_2 photosensitized decomposition of O_3 : the reactions of ClO and OClO with O_3 . *J. Photochem.* **1979**, *10*, 163-186.

F128. $\text{ClO} + \text{H}_2$. The Arrhenius parameters are estimated based on the ~600 K data of Walker (reported in Clyne and Watson¹).

(Table: 82-57, Note: 82-57, Evaluated: 10-6) [Back to Table](#)

- (1) Clyne, M. A. A.; Watson, R. T. Kinetic studies of diatomic free radicals using mass spectrometry Part 2.-Rapid bimolecular reactions involving the $\text{ClO } X^2\Pi$ radical. *J. Chem. Soc. Faraday Trans. 1* **1974**, *70*, 2250-2259.

F129. $\text{ClO} + \text{NO}$. The absolute rate coefficients determined in the four discharge flow-mass spectrometric studies (Clyne and Watson,² Leu and DeMore,⁴ Ray and Watson⁵ and Clyne and MacRobert¹) and the discharge flow laser magnetic resonance study of Lee et al.³ are in excellent agreement at room temperature, and are averaged to yield the recommended value for $k(298 \text{ K})$. The value reported by Zahniser and Kaufman⁷ from a competitive study is not used in the derivation of the recommended value, as it is about 33% higher. The magnitudes of the temperature dependences reported by Leu and DeMore⁴ and Lee et al. are in excellent agreement. Although the E/R value reported by Zahniser and Kaufman⁷ is in fair agreement with the other values, it is not considered as it is dependent upon the E/R value assumed for the $\text{Cl} + \text{O}_3$ reaction. The Arrhenius expression is derived from a least squares fit to the data reported by Clyne and Watson, Leu and DeMore, Ray and Watson, Clyne and MacRobert, and Lee et al. Theoretical rate calculations by Sayin and McKee⁶ give a reaction activation energy (~0.35 kcal/mol) over the temperature range 200–400 K that is supportive of the experimental values.

F130. $\text{ClO} + \text{NO}_3$. The recommended parameters are based on results reported by Cox et al.,³ Cox et al.,⁴ Biggs et al.,² and Kukui et al.⁶ Biggs et al. report the rate constant to be independent of temperature, consistent with the results of Cox et al.⁴ The study of Kukui et al. supersedes the earlier study of Becker et al.¹ from the same laboratory, which had indicated the major products to be $\text{OClO} + \text{NO}_2$. There is now agreement among all studies that the major reaction channel forms $\text{ClOO} + \text{NO}_2$ (see Biggs et al.,² Cox et al.,⁴ and Kukui et al.⁶). From a study of the OClO/NO_3 system, Friedl et al.⁵ conclude that at 220 K the formation of $\text{ClOO} + \text{NO}_2$ is favored.

F134. ClO + H₂CO. Poulet et al.¹ have reported an upper limit of 10⁻¹⁵ cm³ molecule⁻¹ s⁻¹ for k(298 K) using the discharge flow-EPR technique.

(Table: 81-3, Note: 81-3, Evaluated: 81-3) [Back to Table](#)

- (1) Poulet, G.; Le Bras, G.; Combourieu, J. E.P.R. study of the reactivity of ClO with H₂CO at 298 K. *Geophys. Res. Lett.* **1980**, 7, 413-414.

F135. ClO + CH₃O₂. The recommended value for k(298 K) is an average of values derived from the temperature dependent data of Helleis et al.³ (225–355 K), Kukui et al.⁶ (233–300 K), and Leather et al.⁷ (223–298 K). Two other measurements at only room temperature by Simon et al.⁸ and Kenner et al.⁵ are 30% larger and 20% smaller, respectively, but overlap the recommended value within the reported uncertainties.

Helleis et al.³ and Kukui et al.⁶ observed very weak temperature dependences of the rate constant with the reported E/R values of +114 K and –80 K, respectively. The data from these studies differ by less than 40% over the entire temperature range. In contrast, the study by Leather et al.⁷ yielded a much stronger temperature dependence with a reported E/R value of 626 K. Helleis et al.³ and Kukui et al.⁶ used a low pressure discharge flow technique, whereas Leather et al.⁷ employed a turbulent flow reactor with substantially higher pressure. Thus, the data from this latter study should be free from possible interferences due to wall reactions. The combination of lower radical concentrations and higher total pressure in the Leather et al.⁷ study provides the basis for the temperature dependence recommended here. Thus, the recommended value for E/R is derived from a fit to the data of Leather et al.⁷ Nevertheless, in the absence of a definitive explanation for the difference between the results from the high and low pressure studies (which is as large as a factor of 2 to 3 at T = 200 K) values of the uncertainty parameters, f and g, were assigned to encompass the data from all three temperature dependence studies at the 95% confidence level. Note that assymetric values for “g” are assigned in the Table. To determine the upper band for f(T) one should use g = 300, whereas g = 20 should be used to determine the lower band of f(T).

There is general agreement that the only important reaction channels are those resulting in the production of $\text{ClOO} + \text{CH}_3\text{O}$ (a) and $\text{CH}_3\text{OCl} + \text{O}_2$ (b). However, there is disagreement on their relative importance. At room temperature, Helleis et al.,³ Simon et al.,⁸ Kukui et al.,⁶ and Helleis et al.⁴ report that reaction channel (a) is the major channel. However it is reported to be the minor channel by Biggs et al.¹ and Daele and Poulet.² Helleis et al.⁴ (which supersedes the earlier data from Helleis et al.³) found that channel (b) increases from 14% at room temperature to 24% at 220 K whereas Kukui et al.⁶ found this value to increase from 19% at room temperature to 43% at 230 K, i.e., indicating that both channels can be significant at the low temperatures of the polar stratosphere. All studies of the branching ratios were performed using a low-pressure discharge flow technique. Leather et al.⁷ provided no branching ratio information from their higher pressure studies. Given the possibility of the influence of wall processes in the low-pressure studies, no recommendation on the branching ratio is made. Nevertheless, channel (a) appears to play a significant role. F136. $\text{ClO} + \text{ClO}$. There are three bimolecular channels for this reaction:

The recommended values for the individual reaction channels are from the study of Nickolaissen et al.⁸ This study, using a flash photolysis/long path ultraviolet absorption technique, is the most comprehensive study of this system, covering a wide range of temperature and pressure. These results are preferred over the results of earlier studies of the total bimolecular rate coefficient at low pressures by Clyne and Coxon,¹ Clyne and White,³ and Clyne et al.,² and those of other studies reported by Hayman et al.,⁵ Cox and Derwent,⁴ Simon et al.,⁹ Horowitz et al.,⁶ and Horowitz et al.⁷ The room temperature branching ratios are $k_1:k_2:k_3 = 0.29:0.50:0.21$. The reaction exhibits both bimolecular and termolecular reaction channels (see entry in Table 2-1). The termolecular reaction dominates at pressures higher than about 10 Torr. The equilibrium constant for formation of the ClO dimer, ClOOC , is given in Table 3.

F137. HCl + ClONO₂. Five studies of the kinetics of this system have been published, in which the following upper limits to the homogeneous bimolecular rate constant were reported: 10^{-19} cm³ molecule⁻¹ s⁻¹ by a static wall-less long-path UV absorption technique and a steady-state flow FTIR technique (Molina et al.⁶); 5×10^{-18} cm³ molecule⁻¹ s⁻¹ using a flow reactor with FTIR analysis (Friedl et al.³); 8.4×10^{-21} cm³ molecule⁻¹ s⁻¹ using a static photolysis system with FTIR analysis (Hatakeyama and Leu⁴ and Leu et al.⁵); and 1.5×10^{-19} cm³ molecule⁻¹ s⁻¹ by FTIR analysis of the decay of ClONO₂ in the presence of HCl in large-volume (2500 and 5800 liters) Teflon or Teflon-coated chambers (Atkinson et al.¹). Earlier, Birks et al.² had reported a higher upper limit. All studies found this reaction to be catalyzed by surfaces. The differences in the reported upper limits can be accounted for in terms of the very different reactor characteristics and detection sensitivities of the various studies. The recommended upper limit for k(298 K) is based on the studies of Hatakeyama and Leu⁴ and Leu et al.⁵, which apparently are the most sensitive. The homogeneous reaction is too slow to have any significant effect on atmospheric chemistry.

F138. CH₂ClO + O₂. The CH₂ClO radical is reported to be resistant to unimolecular dissociation into Cl + CH₂O products, according to chain reaction/product analysis studies by Sanhueza and Heicklen⁵ and Niki et al.,⁴ and kinetics studies by Catoire et al.² The recommended value for k(298 K) is based on the work of Kaiser and Wallington,³ in which the competition between reaction with O₂ and HCl elimination in a complex photochemical reaction system using FTIR detection of stable products was studied. The recommendation is a factor of 5 higher than estimated using the empirical relationship given by Atkinson and Carter.¹ The fate of CH₂ClO in the atmosphere is reaction with O₂.

F142. $\text{CCl}_2\text{FO}_2 + \text{NO}$. The recommended Arrhenius parameters are based on the measurements made by Dognon et al.¹ using pulsed photolysis with mass spectrometry detection at 1–10 Torr and 228–413 K. These results supersede the earlier study of Lesclaux and Caralp.² The CCl_2FO radical primary product of the $\text{CCl}_2\text{FO}_2 + \text{NO}$ reaction is reported by Lesclaux et al.³ and Wu and Carr⁴ to rapidly decompose to eliminate Cl and to give the products indicated. (Table: 94-26, Note: 94-26, Evaluated: 94-26) [Back to Table](#)

- (1) Dognon, A. M.; Caralp, F.; Lesclaux, R. Réactions des radicaux chlorofluorométhyl peroxy avec NO : Étude cinétique dans le domaine de température compris entre 230 et 430 K. *J. Chim. Phys.* **1985**, 82, 349-352.

1.12 BrO_x Reactions

1.12.1 Table 1G: BrO_x Reactions

Reaction	Temperature Range of Exp. Data (K) ^a	A-Factor	E/R	k(298 K) ^b	f(298 K) ^c	g	Note
O + BrO → Br + O ₂	231–328	1.9×10 ⁻¹¹	–230	4.1×10 ⁻¹¹	1.5	150	G 1
O + HBr → OH + Br	221–554	5.8×10 ⁻¹²	1500	3.8×10 ⁻¹⁴	1.3	200	G 2
O + HOBr → OH + BrO	233–423	1.2×10 ⁻¹⁰	430	2.8×10 ⁻¹¹	3.0	300	G 3
O + BrONO ₂ → NO ₃ + BrO	227–339	1.9×10 ⁻¹¹	–215	3.9×10 ⁻¹¹	1.25	40	G 4
OH + Br ₂ → HOBr + Br	230–360	2.1×10 ⁻¹¹	–240	4.6×10 ⁻¹¹	1.1	50	G 5
OH + BrO → products	230–355	1.7×10 ⁻¹¹	–250	3.9×10 ⁻¹¹	1.4	100	G 6
OH + HBr → H ₂ O + Br	230–360	5.5×10 ⁻¹²	–200	1.1×10 ⁻¹¹	1.1	100	G 7
OH + CH ₃ Br → CH ₂ Br + H ₂ O	233–400	1.42×10 ⁻¹²	1150	3.0×10 ⁻¹⁴	1.07	100	G 8
OH + CH ₂ Br ₂ → CHBr ₂ + H ₂ O	244–375	2.0×10 ⁻¹²	840	1.2×10 ⁻¹³	1.1	100	G 9
OH + CHBr ₃ → CBr ₃ + H ₂ O	230–370	9.0×10 ⁻¹³	360	2.7×10 ⁻¹³	1.05	20	G10
OH + CH ₂ ClBr → CHClBr + H ₂ O	230–376	2.1×10 ⁻¹²	880	1.1×10 ⁻¹³	1.07	100	G11
OH + CHClBr ₂ → CClBr ₂ + H ₂ O	230–330	9.0×10 ⁻¹³	420	2.2×10 ⁻¹³	1.07	20	G12
OH + CHCl ₂ Br → CCl ₂ Br + H ₂ O	230–330	9.4×10 ⁻¹³	510	1.7×10 ⁻¹³	1.07	20	G13
OH + CHF ₂ Br → CF ₂ Br + H ₂ O (Halon-1201)	233–460	7.85×10 ⁻¹³	1300	1.0×10 ⁻¹⁴	1.07	100	G14
OH + CF ₂ Br ₂ → products (Halon-1202)	298	1×10 ⁻¹²	>2200	<5×10 ⁻¹⁶			G15
OH + CF ₃ Br → products (Halon-1301)	460	1×10 ⁻¹²	>3600	<6×10 ⁻¹⁸			G16
OH + CF ₂ ClBr → products (Halon-1211)	373	1×10 ⁻¹²	>3500	<8×10 ⁻¹⁸			G17
OH + CH ₃ CH ₂ Br → products	233–422	2.9×10 ⁻¹²	640	3.4×10 ⁻¹³	1.2	150	G18
OH + CH ₂ BrCH ₂ Br → products	292–366	1.75×10 ⁻¹¹	1290	2.3×10 ⁻¹³	1.15	200	G19
OH + CH ₂ BrCF ₃ → CHBrCF ₃ + H ₂ O (Halon-2301)	280–460	9.5×10 ⁻¹³	1200	1.7×10 ⁻¹⁴	1.2	150	G20
OH + CHFBrCF ₃ → CFBrCF ₃ + H ₂ O (Halon-2401)	279–460	7.3×10 ⁻¹³	1120	1.7×10 ⁻¹⁴	1.2	100	G21
OH + CHClBrCF ₃ → CClBrCF ₃ + H ₂ O (Halothane, Halon-2311)	298–460	1.1×10 ⁻¹²	940	4.7×10 ⁻¹⁴	1.2	150	G22
OH + CHFClCF ₂ Br → CFCICF ₂ Br + H ₂ O	315–372	8.4×10 ⁻¹³	1220	1.4×10 ⁻¹⁴	1.3	200	G23

Shaded areas indicate changes or additions since JPL10-6. Italicized blue text denote estimates.

^a Temperature range of available experimental data. This is not necessarily the range of temperature over which the recommended Arrhenius parameters are applicable. See the corresponding note for each reaction for such information.

^b Units are cm³ molecule⁻¹ s⁻¹.

^c f(298 K) is the uncertainty factor at 298 K. To calculate the uncertainty at other temperatures, use the expression:

$$f(T) = f(298\text{ K}) \exp \left| g \left(\frac{1}{T} - \frac{1}{298} \right) \right|$$

Note that the exponent is an absolute value.

1.12.2 Notes: BrO_x Reactions

- G1. O + BrO.** The preferred value is based on the value reported by Thorn et al.² using a dual laser flash photolysis-long path absorption-resonance fluorescence technique. Clyne et al.¹ reported a value approximately 40% lower.
(Table: 97-4, Note: 97-4, Evaluated: 10-6) [Back to Table](#)
- (1) Clyne, M. A. A.; Monkhouse, P. B.; Townsend, L. W. Reactions of O (³P_J) atoms with halogens: The rate constants for the elementary reactions O + BrCl, O + Br₂, and O + Cl₂. *Int. J. Chem. Kinet.* **1976**, *8*, 425-449.
 - (2) Thorn, R. P.; Cronkhite, J. M.; Nicovich, J. M.; Wine, P. H. Laser flash photolysis studies of radical-radical reaction kinetics: The O(³P_J) + BrO reaction. *J. Chem. Phys.* **1995**, *102*, 4131-4142.
- G2. O + HBr.** Results of the flash photolysis-resonance fluorescence study of Nava et al.² for 221–455 K and the laser flash photolysis-resonance fluorescence study of Nicovich and Wine³ for 250–402 K provide the only data at stratospheric temperatures. Results reported include those of Singleton and Cvetanovic⁴ for 298–554 K by a phase-shift technique, and discharge flow results of Brown and Smith¹ for 267–430 K and Takacs and Glass⁵ at 298 K. The recommended parameters are based on the results of Nava et al., Nicovich and Wine, and Singleton and Cvetanovic over the same temperature range, since these results are less subject to complications due to secondary chemistry than are the results using discharge flow techniques. The uncertainty at 298 K has been set to encompass these latter results.

 - (5) Takacs, G. A.; Glass, G. P. Reaction of atomic oxygen with hydrogen bromide. *J. Phys. Chem.* **1973**, *77*, 1182-1186.
- G3. O + HOBr.** The recommended value for k(298 K) is the mean of results of Monks et al.² and Kukui et al.¹ The temperature dependence is from Nesbitt et al.³ The A-factor from that study has been adjusted to fit the recommended room temperature value. Kukui et al. determined that the Br atom abstraction channel is the only pathway at room temperature.

 - (3) Nesbitt, F. L.; Monks, P. S.; Payne, W. A.; Stief, L. J.; Toumi, R. The reaction O(³P) + HOBr: Temperature dependence of the rate constant and importance of the reaction as an HOBr stratospheric loss process. *Geophys. Res. Lett.* **1995**, *22*, 827-830.
- G4. O + BrONO₂.** The recommendation is based on the study of Soller et al.² using a laser flash photolysis–resonance fluorescence technique over the temperature range 227–339 K. The recommended uncertainty parameters are larger than those reported by Soller et al. pending independent confirmation of their results. Burkholder¹ has coupled laser flash photolysis with detection of NO₃ by long path absorption spectroscopy to show that the NO₃ yield is >0.85 at 298 K.

- G5. OH + Br₂.** The recommended value for $k(298\text{ K})$ is the average of the values reported by Poulet et al.,⁵ Loewenstein and Anderson,⁴ Gilles et al.,³ and Bedjanian et al.¹ The temperature dependence is an average of the E/R values of Gilles et al. and Bedjanian et al. The room temperature results of Boodaghians et al.² are 40% lower than the recommended value for $k(298\text{ K})$ and were not considered due to their large experimental uncertainty. Loewenstein and Anderson determined that the exclusive products are Br + HOBr.

 - (4) Loewenstein, L. M.; Anderson, J. G. Rate and product measurements for the reactions of OH with Cl₂, Br₂, and BrCl at 298 K. Trend interpretations. *J. Phys. Chem.* **1984**, *88*, 6277-6286, doi:10.1021/j150669a045.
 - (5) Poulet, G.; Laverdet, G.; Le Bras, G. Kinetics and products of the reaction of hydroxyl radical with molecular bromine. *Chem. Phys. Lett.* **1983**, *94*, 129-132.
- G6. OH + BrO.** The recommended value of $k(298\text{ K})$ is an average of the results of Gilles et al.² and Bedjanian et al.¹ The only temperature-dependent study is from Bedjanian et al. The recommendation for E/R is based on their results. The likely products of this reaction are Br + HO₂. Bedjanian et al. attempted to measure the branching ratio for HBr formation, but there were significant problems from secondary chemistry. An upper limit of 3% was reported for the HBr yield.
(Table: 06-2, Note: 06-2, Evaluated: 06-2) [Back to Table](#)
- (1) Bedjanian, Y.; Riffault, V.; Le Bras, G.; Poulet, G. Kinetics and mechanism of the OH and OD reactions with BrO. *J. Phys. Chem. A* **2001**, *105*, 6154-6166, doi:10.1021/jp010369q.

- G7. OH + HBr.** The recommended value for $k(298\text{ K})$ is the average of the values reported by Ravishankara et al.⁷ using FP-RF, Jourdain et al.⁶ using DF-EPR, Cannon et al.³ using FP-LIF, Ravishankara et al.⁸ using LFP-RF and LFP-LIF, and Bedjanian et al.² using DF-MS. Values reported by Takacs and Glass¹¹ and Husain et al.⁴ as well as the preliminary value of Smith and Zellner¹⁰ are a factor of 2 lower and were not included in the derivation of the recommended value. The recommendation for the temperature dependence is derived from the data of Bedjanian et al.² This study obtained a small negative temperature dependence that is in qualitative agreement with the Laval nozzle studies of Sims et al.,⁹ Atkinson et al.,¹ and Jaramillo et al.⁵ over the 200–300 K temperature range. The data of Ravishankara et al.⁷ show no dependence on temperature over the range 249–416 K.

G8. OH + CH₃Br. There are four studies of this reaction using different techniques that report 298 K rate constant values agreeing to within 10% and data that agree to better than 30% over a broad range of temperatures. The recommended value for $k(298\text{ K})$ was obtained from an average of the data from these four studies: the relative rate study of Hsu and DeMore⁴ (recalculated based on the recommendation for the rate constant for the OH + CH₃CHF₂ reference reaction given in the present evaluation and as discussed in the note for that reaction) and the absolute determinations by Chichinin et al.,¹ Mellouki et al.,⁵ and Zhang et al.⁷ The results of these extensive studies are preferred over the higher values reported in the earlier studies of Davis et al.² and Howard and Evenson.³ Although the room temperature value reported by Howard and Evenson³ is ~20% larger, it overlaps the recommended value within the reported experimental uncertainty. The data from Davis et al.² yield a $k(298\text{ K})$ value that is more than 30% larger than recommended, with the difference between their measured rate constants and those recommended increasing at lower temperatures. This is suggestive of the presence of reactive impurities in the sample of methyl bromide. Also considered, but not used in deriving the recommended Arrhenius parameters are data from the relative rate and absolute studies of Nilsson et al.⁶ These data lie higher than the results from almost all of the previous measurements, and exceed the recommended value of $k(298\text{ K})$ by ~38% and 60%, respectively. The relative rate results barely overlap the recommended $k(298\text{ K})$ value within the combined 95% confidence limits when the uncertainties in the reference rate constants are included. While the high rate constants obtained in the absolute measurements of Nilsson et al. cannot be explained, significantly higher rate constant values were also previously obtained using the same apparatus for the OH reactions with HFC-152a and HCFC-123. The recommended value for E/R was derived from a fit to the data of Mellouki et al.⁵ below 300 K. The somewhat more scattered low temperature data of Chichinin et al.¹ and Zhang et al.⁷ are encompassed within the recommended uncertainties.

G9. OH + CH₂Br₂. The recommended value for $k(298\text{ K})$ is an average of the values from the absolute studies of Mellouki et al.² and Zhang et al.⁴ and from the relative rate measurements of DeMore¹ (recalculated based on the recommendation for the rate constant for the OH + CH₂Cl₂ reference reaction given in this evaluation) and Orlando et al.³ (recalculated based on the recommendation for the rate constant for the OH + CH₃C(O)CH₃ reference reaction given in this evaluation). The recommended value of E/R is derived from an Arrhenius fit to the data of Mellouki et al.² The uncertainty parameters reflect the latest understanding of the reactivities of this and similar compounds.

G10. OH + CHBr₃. The recommended Arrhenius parameters are derived from the data from the absolute rate study of Orkin et al.² The results from the relative rate study of DeMore¹ (recalculated based on the recommendation for the rate constant for the OH + CH₂Cl₂ reference reaction given in this evaluation) lie systematically lower and exhibit a stronger temperature dependence. The results of the Orkin et al.² investigation have been used in the rate constant recommendations for the OH reactions with CHBr₃, CHClBr₂, and CHCl₂Br. The observed systematic changes in the rate constants and temperature dependences found in this study are consistent with expectations based on increasing Cl atom substitution.

G11. OH + CH₂ClBr. The recommended value for k(298 K) is an average of the values from two relative rate studies by DeMore² (recalculated based on the recommended rate constant for the OH + CH₂Cl₂ reference reaction) and Bilde et al.¹ (recalculated using the recommended rate constant for the OH + CH₂Br₂ reference reaction) and two absolute determinations by Orkin et al.,³ all of which are in good agreement. The recommended E/R is obtained from a fit to the data of DeMore and Orkin et al. after scaling each data set to the recommended k(298 K).

(Table: 15-10, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

- (3) Orkin, V. L.; Khamaganov, V. G.; Guschin, A. G.; Huie, R. E.; Kurylo, M. J. Atmospheric fate of chlorobromomethane: Rate constant for the reaction with OH, UV spectrum, and water solubility. *J. Phys. Chem. A* **1997**, *101*, 174-178.

G12. OH + CHClBr₂. The recommended Arrhenius parameters are derived from the data from the absolute rate study of Orkin et al.¹ As discussed in the note for the reaction of OH with CHBr₃, the observed systematic changes in the rate constants for the OH reactions with CHBr₃, CHClBr₂, and CHCl₂Br and the temperature dependences found in this study are consistent with expectations based on increasing Cl atom substitution and provide the basis for the assignment of the uncertainty parameters.

(Table: 15-10, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

- (1) Orkin, V. L.; Khamaganov, V. G.; Kozlov, S. N.; Kurylo, M. J. Measurements of rate constants for the OH reactions with bromoform (CHBr₃), CHBr₂Cl, CHBrCl₂, and epichlorohydrin (C₃H₅ClO). *J. Phys. Chem. A* **2013**, *117*, 3809-3818, doi:10.1021/jp3128753.

G13. OH + CHCl₂Br. The recommended Arrhenius parameters are derived from the data from the absolute rate study of Orkin et al.² As discussed in the note for the reaction of OH with CHBr₃, the observed systematic changes in the rate constants for the OH reactions with CHBr₃, CHClBr₂, and CHCl₂Br and the temperature dependences found in this study are consistent with expectations based on increasing Cl atom substitution and provide the basis for the assignment of the uncertainty parameters. The room temperature rate constants determined in the relative rate study by Bilde et al.¹ (recalculated using the recommended rate constants for

the OH + CH₂Br₂ and CH₂ClBr reference reactions) lie approximately 20% and 50% lower respectively than recommended.

(Table: 15-10, Note: 15-10, Evaluated 15-10) [Back to Table](#)

- (1) Bilde, M.; Wallington, T. J.; Ferronato, C.; Orlando, J. J.; Tyndall, G. S.; Estupiñan, E.; Haberkorn, S. Atmospheric chemistry of CH₂BrCl, CHBrCl₂, CHBr₂Cl, CF₃CHBrCl, and CBr₂Cl₂. *J. Phys. Chem. A* **1998**, *102*, 1976-1986, doi:10.1021/jp9733375.
- (2) Orkin, V. L.; Khamaganov, V. G.; Kozlov, S. N.; Kurylo, M. J. Measurements of rate constants for the OH reactions with bromoform (CHBr₃), CHBr₂Cl, CHBrCl₂, and epichlorohydrin (C₃H₅ClO). *J. Phys. Chem. A* **2013**, *117*, 3809-3818, doi:10.1021/jp3128753.

G14. OH + CHF₂Br (Halon-1201). There are very consistent results from four studies of this reaction: Talukdar et al.⁴ (using two different measurement techniques, DF-LMR and PLP-LIF), Orkin and Khamaganov³ (using DF-EPR), and Hsu and DeMore² (relative rate measurements recalculated using the recommended rate constant for the OH + CH₄ reference reaction). Talukdar et al.⁴ noted a slight curvature in the Arrhenius plot at the higher temperatures, which is also supported by the data from Orkin and Khamaganov.³ Below 400 K, all four data sets exhibit nearly identical temperature dependences with E/R values ranging from 1271 to 1338 K⁻¹. The recommended value for k(298 K) is an average of the rate constants derived from each of the four studies. The recommended value for E/R is derived from a combined fit to the data from these four studies below 400 K after each data set was scaled to the recommended k(298 K). These data are preferred over the consistently higher results reported by Brown et al.¹

(Table: 15-10, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

- (1) Brown, A. C.; Canosa-Mas, C. E.; Parr, A. D.; Rothwell, K.; Wayne, R. P. Tropospheric lifetimes of three compounds for possible replacement of CFC and halons. *Nature* **1990**, *347*, 541-543.
- (2) Hsu, K. J.; DeMore, W. B. Rate constants and temperature dependences for the reactions of hydroxyl radical with several halogenated methanes, ethanes, and propanes by relative rate measurements. *J. Phys. Chem.* **1995**, *99*, 1235-1244.
- (3) Orkin, V. L.; Khamaganov, V. G. Rate constants for reactions of OH radicals with some Br-containing haloalkanes. *J. Atmos. Chem.* **1993**, *16*, 169-178.

G15. OH + CF₂Br₂ (Halon-1202). The A factor was estimated and a lower limit for E/R was derived using the upper limit for the 298 K rate constant reported by Burkholder et al.¹ in a study using pulsed photolysis-LIF and DF-LMR techniques.

(Table: 02-25, Note: 02-25, Evaluated: 15-10) [Back to Table](#)

- (1) Burkholder, J. B.; Wilson, R. R.; Gierczak, T.; Talukdar, R.; McKeen, S. A.; Orlando, J. J.; Vaghjiani, G. L.; Ravishankara, A. R. Atmospheric fate of CF₃Br, CF₂Br₂, CF₂ClBr, and CF₂BrCF₂Br. *J. Geophys. Res.* **1991**, *96*, 5025-5043.

G16. OH + CF₃Br (Halon-1301). The A-factor was estimated and a lower limit for E/R was derived using the upper limit for the 460 K rate constant reported by Orkin and Khamaganov.³ These parameters were then used to calculate an upper limit for k(298 K). The upper limit for k(298 K) determined by Burkholder et al.¹ using pulsed photolysis-LIF and DF-LMR techniques at room temperature is understandably higher. A less sensitive upper limit was also reported by Le Bras and Combourieu.²

- (3) Orkin, V. L.; Khamaganov, V. G. Rate constants for reactions of OH radicals with some Br-containing haloalkanes. *J. Atmos. Chem.* **1993**, *16*, 169-178.

G17. OH + CF₂ClBr (Halon-1211). A lower limit for E/R was derived using an estimated A factor of 1 × 10⁻¹² and the upper limit for the 373 K rate constant reported by Burkholder et al.¹ in a study using pulsed photolysis-LIF and DF-LMR techniques. A less sensitive upper limit was reported by Clyne and Holt.²

(Table: 15-10, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

- (1) Burkholder, J. B.; Wilson, R. R.; Gierczak, T.; Talukdar, R.; McKeen, S. A.; Orlando, J. J.; Vaghjiani, G. L.; Ravishankara, A. R. Atmospheric fate of CF_3Br , CF_2Br_2 , CF_2ClBr , and $\text{CF}_2\text{BrCF}_2\text{Br}$. *J. Geophys. Res.* **1991**, 96, 5025-5043.
- (2) Clyne, M. A. A.; Holt, P. M. Reaction kinetics involving ground $X^2\Pi$ and excited $A^2\Sigma^+$ hydroxyl radicals Part 1.-Quenching kinetics of OH $A^2\Sigma^+$ and rate constants for reactions of OH $X^2\Pi$ with CH_3CCl_3 and CO. *J. Chem. Soc. Faraday Trans. 2* **1979**, 75, 569-581.

G18. OH + $\text{CH}_3\text{CH}_2\text{Br}$. The recommended values for $k(298\text{ K})$ and E/R are derived from a fit to the data ($T \leq 300\text{ K}$) of Herndon et al.² These data suggest a curvature of the Arrhenius plot similar to that found for the OH reaction with $\text{CH}_3\text{CH}_2\text{F}$. The data of Qiu et al.³ (which include earlier data reported by the same research group in Xing et al.⁴) were not used because they were obtained mainly above room temperature and exhibit a very steep temperature dependence resulting in a value for E/R that is larger than the E/R value obtained from data at $T > 298\text{ K}$ for the OH reaction with $\text{CH}_3\text{CH}_2\text{F}$. The $k(300\text{ K})$ value reported by Donaghy et al.¹ seems too low for this reaction when compared with the recommendation for the presumably slower (and better studied) OH reaction with $\text{CH}_3\text{CH}_2\text{F}$.

- (2) Orkin, V. L.; Khamaganov, V. G. Rate constants for reactions of OH radicals with some Br-containing haloalkanes. *J. Atmos. Chem.* **1993**, *16*, 169-178.

G25. OH + CH₂BrCH₂CH₃. The recommended value for k(298 K) is an average of k(298 K) values derived from Arrhenius fits to the data from Donaghy et al.¹ (using cyclopropane as the reference reactant), Teton et al.,⁶ Nelson et al.,⁵ Herndon et al.,³ Gilles et al.,² and Kozlov et al.⁴ Significant curvature in the Arrhenius plot has been observed over the 480 K to 210 K temperature range, due to the three different hydrogen-abstraction reaction channels. These channels have been quantified in the study of Gilles et al. In spite of the noticeable Arrhenius curvature, the data below 300 K can be reasonably well represented by a two-parameter Arrhenius expression. The recommended value of E/R is an average of the E/R values obtained from fits to the data (for T ≤ 300 K) from Gilles et al.² and Kozlov et al.⁴ The data over the complete temperature range (210–480 K) can be represented by the three-parameter equation from Kozlov et al.⁴

$$k(T) = 3.0 \times 10^{-13} (T/298)^{2.8} \exp(+369/T)$$

(Table: 10-6, Note: 15-10, Evaluated: 10-6) [Back to Table](#)

- (1) Donaghy, T.; Shanahan, I.; Hande, M.; Fitzpatrick, S. Rate constants and atmospheric lifetimes for the reactions of OH radicals and Cl atoms with haloalkanes. *Int. J. Chem. Kinet.* **1993**, *25*, 273-284.
- (2) Gilles, M. K.; Burkholder, J. B.; Gierczak, T.; Marshall, P.; Ravishankara, A. R. Rate coefficient and product branching measurements for the reaction OH + bromopropane from 230 to 360 K. *J. Phys. Chem. A* **2002**, *104*, 8945-8950, doi:10.1021/jp014736+.
- (3) Herndon, S. C.; Gierczak, T.; Talukdar, R. K.; Ravishankara, A. R. Kinetics of the reactions of OH with several alkyl halides. *Phys. Chem. Chem. Phys.* **2001**, *3*, 4529-4535, doi:10.1039/b105188c.

G26. OH + CH₃CHBrCH₃. The recommendation for k(298 K) is an average of the values derived from the absolute rate studies of Herndon et al.,³ Kozlov et al.,⁴ and Bryukov et al.¹ and from the relative rate study of Donaghy et al.² (using cyclopropane as the reference reactant). Significant curvature in the Arrhenius plot has been observed over the 480 K to 210 K temperature range, presumably due to the existence of two different hydrogen-abstraction channels. In spite of the noticeable Arrhenius curvature, the data below 300 K can be reasonably well represented by a two-parameter Arrhenius fit. The recommended value for E/R is an average of the parameters derived from Arrhenius fits to the data (T ≤ 300 K) of Herndon et al.³ and Kozlov et al.,⁴ which are in excellent agreement. The absolute temperature-dependent data of Teton et al.⁵ lie systematically higher than those from the three more recent studies. The data over the complete temperature range (210 K – 480 K) can be represented by the three-parameter equation from Kozlov et al.⁴

$$k(T) = 1.66 \times 10^{-13} (T/298)^{2.95} \exp(+461/T)$$

(Table: 10-6, Note: 15-10, Evaluated: 10-6) [Back to Table](#)

G27. OH + CHBr=CF₂. The recommended Arrhenius parameters are derived from the data of Orkin et al.¹

(Table: 15-10, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

- (1) Orkin, V. L.; Louis, F.; Huie, R. E.; Kurylo, M. J. Photochemistry of bromine-containing fluorinated alkenes: Reactivity toward OH and UV spectra. *J. Phys. Chem. A* **2002**, *106*, 10195-10199, doi:10.1021/jp014436s.

G28. OH + CFBr=CF₂. The recommended Arrhenius parameters are derived from the data of Orkin et al.¹

(Table: 15-10, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

- (1) Orkin, V. L.; Louis, F.; Huie, R. E.; Kurylo, M. J. Photochemistry of bromine-containing fluorinated alkenes: Reactivity toward OH and UV spectra. *J. Phys. Chem. A* **2002**, *106*, 10195-10199, doi:10.1021/jp014436s.

G29. OH + CH₂=CBrCF₃. The recommended Arrhenius parameters are derived from a fit to the data (T < 300 K) of Patten et al.² Earlier, less extensive data from the same laboratory (Orkin et al.¹) are in excellent agreement. The room temperature data from the relative rate study of Sulbaek-Andersen et al.³ are also in very good agreement after recalculation using the latest recommended values for the reference reactions. While a standard Arrhenius parameterization provides a very good representation of the rate constants below room temperature, a pronounced curvature can be seen in the data over the full temperature range. Thus, the data over the complete temperature range (220–370 K) can be represented by the three-parameter equation

$$k(T) = 4.85 \times 10^{-13} (T/298)^{0.92} \exp(+613/T)$$

(Table: 15-10, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

G31. OH + CH₂=CHCF₂CF₂Br. The recommended Arrhenius parameters are derived from the data of Orkin et al.¹

(Table: 15-10, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

- (1) Orkin, V. L.; Louis, F.; Huie, R. E.; Kurylo, M. J. Photochemistry of bromine-containing fluorinated alkenes: Reactivity toward OH and UV spectra. *J. Phys. Chem. A* **2002**, *106*, 10195-10199, doi:10.1021/jp014436s.

G32. HO₂ + Br. The recommended value for k(298 K) was obtained from an average of the results of Laverdet et al.,² Toohey et al.,⁵ and Bedjanian et al.¹ The results of Posey et al.³ were not considered because of problems with the experimental method. The results of Poulet et al.⁴ were also not considered because of complications associated with secondary reactions. The recommendation for the temperature dependence is based on the results of Bedjanian et al.¹

(Table: 06-2, Note: 06-2, Evaluated: 06-2) [Back to Table](#)

- (1) Bedjanian, Y.; Riffault, V.; Le Bras, G.; Poulet, G. Kinetic study of the reactions of Br with HO₂ and DO₂. *J. Phys. Chem. A* **2001**, *105*, 573-578, doi:10.1021/jp002731r.

G33. HO₂ + BrO. The recommendation for E/R is based on results of the temperature-dependent studies of Elrod et al.,⁵ Li et al.,⁷ and Bedjanian et al.¹ It is assumed that the Bedjanian et al. results supersede those of Larichev et al.⁶ since the same experimental technique was used, and the same research group was involved in both studies. The recommended value of k(298 K) is the mean of the values reported in these studies, as well as those of Cronkhite et al.⁴ and Bloss et al.² The room temperature value of Bridier et al.,³ which was not obtained under pseudo-first-order decay conditions, was not included in derivation of the recommendation. Bedjanian et al. have determined an upper limit of 0.4% for production of HBr and O₃ at 298 K. From a study of the reverse reaction above room temperature, Mellouki et al.⁸ determined by extrapolation that the yield of HBr + O₃ is an insignificant fraction (<0.01%) of the total reaction down to 200 K.

G34. NO₃ + HBr. The recommendation accepts the upper limit reported by Mellouki et al.² in a study using DF-EPR techniques. This upper limit shows that this reaction is of negligible importance in stratospheric chemistry. Canosa-Mas et al.¹ reported a value that is consistent, within experimental error, with the upper limit of Mellouki et al.

(Table: 90-1, Note: 92-20, Evaluated: 10-6) [Back to Table](#)

- (2) Mellouki, A.; Poulet, G.; Le Bras, G.; Singer, R.; Burrows, J. P.; Moortgat, G. K. Discharge flow kinetic study of the reactions of NO₃ with Br, BrO, HBr, and HCl. *J. Phys. Chem.* **1989**, *93*, 8017-8021, doi:10.1021/j100361a012.

G35. Cl + CH₃Br. The recommended value for k(298 K) is an average of the results from the absolute rate studies of Gierczak et al.,¹ Kambanis et al.,³ and Piety et al.,⁵ and from the relative rate study of Orlando et al.⁴ The recommended value for E/R is derived from a combined fit to the data from these same four studies restricted to temperatures of 400 K and below after scaling of each data set to the recommended value of k(298 K). Results of the relative rate study of Tschuikow-Roux et al.⁶ were not used in the derivation of the recommended values since they appear to be systematically higher than the results of the other investigations. The products of this reaction are expected to primarily be CH₂Br and HCl. The possible production of CH₃Cl + Br is very small in the atmosphere.² While a standard Arrhenius parameterization provides a very good representation of the rate constants below 400 K, a pronounced curvature can be seen in the data of Piety et al.⁵ particularly above 400 K. The data over the complete temperature range (210–700 K) can be represented by the three-parameter equation

$$k(T) = 4.60 \times 10^{-12} (T/298)^{1.2} \exp(-700/T)$$

G36. Cl + CH₂Br₂. The recommended value for k(298 K) is an average of the results from the absolute rate studies of Gierczak et al.¹ and Kambanis et al.² and from the three relative rate experiments of Orlando et al.³ The recommended value for E/R is based on a combined fit to the data (T < 300 K) from these same studies after scaling each one to the recommended value for k(298 K). Results of the relative rate study of Tschuikow-Roux et al.⁴ were not used in derivation of the recommended parameters since they are

significantly greater at 298 K and correspond to a temperature dependence substantially stronger than derived from the data of other investigations.

(Table: 06-2, Note: 06-2, Evaluated: 06-2) [Back to Table](#)

- (1) Gierczak, T.; Goldfarb, L.; Sueper, D.; Ravishankara, A. R. Kinetics of the reactions of Cl atoms with CH₃Br and CH₂Br₂. *Int. J. Chem. Kinet.* **1994**, 26, 719-728.
- (2) Kambanis, K. G.; Lazarou, Y. G.; Papagiannakopoulos, P. J. Absolute rate constants for the reactions of Cl atoms with CH₃Br, CH₂Br₂, and CHBr₃. *J. Phys. Chem.* **1997**, 101, 8496-8502, doi:10.1021/jp9719671.
- (3) Orlando, J. J.; Tyndall, G. S.; Wallington, T. J.; Dill, M. Atmospheric chemistry of CH₂Br₂: Rate coefficients for its reaction with Cl atoms and OH and the chemistry of the CHBr₂O radical. *Int. J. Chem. Kinet.* **1996**, 28, 433-442.

G37. Cl + CHBr₃. The recommended parameters are based on the only reported study of this reaction by Kambanis et al.,¹ which employed a very low pressure reactor and monitored reactants and products using mass spectrometry.

(Table: 06-2, Note: 06-2, Evaluated: 06-2) [Back to Table](#)

- (1) Kambanis, K. G.; Lazarou, Y. G.; Papagiannakopoulos, P. J. Absolute rate constants for the reactions of Cl atoms with CH₃Br, CH₂Br₂, and CHBr₃. *J. Phys. Chem.* **1997**, 101, 8496-8502, doi:10.1021/jp9719671.

G38. Cl + CH₂ClBr. The recommended value for k(298 K) is an average of two relative rate determinations by Bilde et al.¹ (recalculated based on the recommended rate constants for the reference reactions). The temperature dependence is estimated from a comparison with the reactions of Cl with CH₂Cl₂ and CH₂Br₂. The relative rate investigation by Tschuikow-Roux et al.² gives a value for k(298 K) only slightly larger than recommended, but a temperature dependence that is significantly stronger and inconsistent with that recommended for the Cl + CH₂Cl₂ and Cl + CH₂Br₂ reactions.

(Table: 06-2, Note: 06-2, Evaluated: 06-2) [Back to Table](#)

G39. Br + O₃. The results reported for k(298 K) by Clyne and Watson,¹ Leu and DeMore,² Michael et al.,³ Michael and Payne,⁴ Toohey et al.,⁷ Nicovich et al.,⁵ and Ninomiya et al.⁶ are in excellent agreement. The recommended value at 298 K is derived as the mean of these seven values. There is less agreement among reported temperature dependences, with E/R values ranging from ~900 K⁻¹ (Leu and DeMore and Toohey et al.) to ~600 K⁻¹ (Michael et al. and Michael and Payne). The recommended value of E/R is an average of the E/R values from the five temperature-dependent studies (not including Clyne and Watson and Ninomiya et al., which were room temperature only).

G40. Br + H₂O₂. The recommended upper limit for k(298 K) is based on results reported by Toohey et al.⁵ using a discharge flow-resonance fluorescence-laser magnetic resonance technique. Their upper limit determined over the temperature range 298–378 K is consistent with less sensitive upper limits determined by Leu² and Posey et al.⁴ using a discharge flow-mass spectrometric technique. The much higher value reported by Heneghan and Benson¹ may result from the presence of excited Br atoms in their very low pressure reactor. The pre-exponential factor was estimated to be consistent with that for the Cl + H₂O₂ rate constant, and the E/R value was fit to the upper limit at 298 K. Mellouki et al.³ have measured the rate of the reverse reaction. (Table: 87-41, Note: 94-26, Evaluated: 10-6) [Back to Table](#)

G41. Br + NO₃. The recommended value of k(298 K) is that reported by Mellouki et al.¹ in a study using DF-EPR techniques.

(Table: 90-1, Note: 92-20, Evaluated: 10-6) [Back to Table](#)

- (1) Mellouki, A.; Poulet, G.; Le Bras, G.; Singer, R.; Burrows, J. P.; Moortgat, G. K. Discharge flow kinetic study of the reactions of NO₃ with Br, BrO, HBr, and HCl. *J. Phys. Chem.* **1989**, 93, 8017-8021, doi:10.1021/j100361a012.

G42. Br + H₂CO. There have been two direct studies of this rate constant as a function of temperature: Nava et al.,² using a flash photolysis–resonance fluorescence technique, and Poulet et al.,³ using a discharge flow-mass spectrometric technique. These results are in reasonably good agreement. The recommended Arrhenius parameters were derived from a least squares fit to the data reported in these two studies. The higher room temperature value of Le Bras et al.,¹ using a discharge flow–EPR technique, has been shown to be in error due to secondary chemistry (Poulet et al.). The relative rate study of Ramacher et al.⁴ is in good agreement with the recommendation.

G43. Br + CH₂=C(CH₃)CHO. A single relative rate study by Sauer et al.,² which employed air as the bath gas at P = 1 atm and T = 301 K, has been reported. The process studied by Sauer et al. is not an elementary reaction. The overall rate constant for loss of methacrolein (CH₂=C(CH₃)CHO) via a multi-reaction sequence was measured relative to the overall rate constant for loss of trans-2-butene via a similar multi-reaction sequence. The multi-reaction sequence involves addition of Br to the alkenes to form bromo-alkyl radicals that react with O₂ in competition with decomposition back to Br + alkene reactants. The rate constant for the reference reaction (Br + trans-2-butene) was measured relative to Br + propene, and the relative rate constants

were put on an absolute scale by measuring the Br + propene rate constant relative to that of the well-studied H-abstraction reaction Br + CH₃CHO.¹ A complicated dependence of the overall rate constant on temperature, pressure, and [O₂] is likely, so the recommended rate constant and associated uncertainty are only appropriate for temperatures close to 301 K, pressures close to 1 atm, and O₂ mixing ratios close to those present in air. Sauer et al. report that, at P = 1 atm N₂ + O₂ and T = 301 K, the observed rate constant increases by nearly a factor of 4 as the O₂ partial pressure increases from 0.027 to 1.00 atm. In 900 mbar of synthetic air at 296 K, the following molar product yields are reported by Sauer et al.: HBr, ~0; CH₃C(O)CH₂Br, 0.60 ± 0.09; CO, 0.68 ± 0.08, CO₂, 0.10 ± 0.03; H₂CO, 0.08 ± 0.03. Small yields of CH₃OH and CH₃OOH are also reported. Sauer et al. conclude that the dominant reaction pathway is addition of Br to the terminal carbon atom of the double bond.

G44. Br + CH₃C(O)CH=CH₂. A single relative rate study by Sauer et al.,² which employed air as the bath gas at P = 1 atm and T = 301 K, has been reported. The process studied by Sauer et al. is not an elementary reaction. The overall rate constant for loss of MVK (CH₃C(O)CH=CH₂) via a multi-reaction sequence was measured relative to the overall rate constant for loss of trans-2-butene via a similar multi-reaction sequence. The multi-reaction sequence involves addition of Br to the alkenes to form bromo-alkyl radicals that react with O₂ in competition with decomposition back to Br + alkene reactants. The rate constant for the reference reaction (Br + trans-2-butene) was measured relative to Br + propene, and the relative rate constants were put on an absolute scale by measuring the Br + propene rate constant relative to that of the well-studied H-abstraction reaction Br + CH₃CHO.¹ A complicated dependence of the overall rate constant on temperature, pressure, and [O₂] is likely, so the recommended rate constant and associated uncertainty are only appropriate for temperatures close to 301 K, pressures close to 1 atm, and O₂ mixing ratios close to those present in air. Sauer et al. report that, at P = 1 atm N₂ + O₂ and T = 301 K, the observed rate constant increases by about a factor of 2.5 as the O₂ partial pressure increases from 0.027 to 0.395 atm. In 900 mbar of synthetic air at 296 K, the following molar product yields are reported by Sauer et al.: HBr, ~0; CH₂BrCHO, 1.13 ± 0.21; CO₂, 0.61 ± 0.09; H₂CO, 0.39 ± 0.05. Small yields of CH₃OH, CH₃OOH, CH₃C(O)OH, and CH₃C(O)OOH are also reported. Sauer et al. conclude that the dominant reaction pathway is addition of Br to the terminal carbon atom of the double bond.

(Table 15-10, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

- (1) Bierbach, A.; Barnes, I.; Becker, K. H. Rate coefficients for the gas-phase reactions of bromine series of radicals with alkenes, dienes, and aromatic hydrocarbons at 298 ± 2 K. *Int. J. Chem. Kinet.* **1996**, 28, 565-577.
- (2) Sauer, C. G.; Barnes, I.; Becker, K. H. FT-IR kinetic and product study of the Br-radical initiated oxidation of α, β-unsaturated organic carbonyl compounds. *Atmos. Environ.* **1999**, 33, 2969-2979, doi:10.1016/S1352-2310(99)00085-0.

G45. Br + CH₂=C(CH₃)CH=CH₂ $\xrightleftharpoons{M}$ adduct $\xrightleftharpoons{O_2}$ products. One relative rate study by Bierbach et al.,¹ which employed air as the bath gas at P = 1 bar and T = 298 K, has been reported. The process studied by Bierbach et al. is not an elementary reaction. The overall rate constant for loss of isoprene via the above multi-reaction sequence was measured relative to the overall rate constant for loss of 1,3-butadiene via a similar multi-reaction sequence; a sequence of relative rate studies were carried out using progressively less reactive reference compounds (2,3-dimethyl-2-butene, trans-2-butene, propene, and acetaldehyde (CH₃CHO), with all relative rate constants being put on an absolute scale using the well-known rate constant for the elementary H-abstraction reaction of Br with CH₃CHO. A Br + CH₂=C(CH₃)CH=CH₂ rate constant of 7.4 × 10⁻¹¹ cm³ molecule⁻¹ s⁻¹, about a factor of three smaller than the gas kinetic collision rate constant, is reported by Bierbach et al. The uncertainty in the rate constant reported by Bierbach et al. is substantial because (i) five rate constant ratios had to be measured to extract the desired rate constant and (ii) all reactions studied except Br + CH₃CHO occurred via complex reaction sequences. Laine et al.² have reported a laser flash photolysis–resonance fluorescence study where monitoring of Br kinetics as a function of temperature, pressure, [CH₂=C(CH₃)CH=CH₂], and [O₂] has allowed elementary rate constants for H abstraction, Br addition, adduct decomposition, and adduct reaction with O₂ to be deduced; these authors also estimated the

temperature dependence of the adduct–O₂ unimolecular decomposition rate constant. The results of Laine et al. suggest that in the atmosphere CH₂=C(CH₃)CH=CH₂ is lost irreversibly on essentially every collision with Br at temperatures below 275 K. At higher temperatures, Laine et al. suggest that Br + CH₂=C(CH₃)CH=CH₂ may be regenerated via unimolecular reactions rapidly enough to compete with bimolecular reactions of the peroxy radical(s) both in the atmosphere and in environmental chambers. Until additional information becomes available, a recommendation that would prove useful for atmospheric modeling, particularly in warmer environments, cannot be made.

- (2) Laine, P. L.; Sohn, Y. S.; Nicovich, J. M.; McKee, M. L.; Wine, P. H. Kinetics of elementary steps in the reactions of atomic bromine with isoprene and 1,3-butadiene under atmospheric conditions. *J. Phys. Chem. A* **2012**, *116*, 6341-6357, doi:10.1021/jp212127v.

G46. Br + CH₂=C(CH₃)CH=CH₂ → CH₂=C(•CH₂)CH=CH₂ + HBr. The recommendation is based on the results of Laine et al.¹ at temperatures (526–673 K) where adduct decomposition is so rapid that the adduct represents a negligible reservoir for Br. The estimated uncertainty is large because data are only available from a single study and because the long extrapolation to the atmospherically relevant temperature regime (200–300 K) is based on the assumption of Arrhenius behavior. The recommended uncertainty spans all values consistent with the 2σ error limits for A and E/R reported by Laine et al.

(Table: 15-10, Note: 15-10, Evaluated: 15-10). [Back to Table](#)

- (1) Laine, P. L.; Sohn, Y. S.; Nicovich, J. M.; McKee, M. L.; Wine, P. H. Kinetics of elementary steps in the reactions of atomic bromine with isoprene and 1,3-butadiene under atmospheric conditions. *J. Phys. Chem. A* **2012**, *116*, 6341-6357, doi:10.1021/jp212127v.

G47. Br–CH₂=C(CH₃)CH=CH₂ + O₂ → products. The recommendation is based on the results of Laine et al.,¹ who extracted kinetic information from observation of the effect of added O₂ on the kinetics of Br equilibration with Br–CH₂=C(CH₃)CH=CH₂ following laser flash photolysis of CF₂Br₂/CH₂=C(CH₃)CH=CH₂/N₂/O₂ mixtures. The obtained rate constant at T = 297 K was found to be independent of pressure over the range 50 to 700 Torr (mostly N₂). There are several possible isomers of Br–CH₂=C(CH₃)CH=CH₂; calculations (G4 method) reported by Laine et al. show that the energetically most stable isomer is CH₂BrC•(CH₃)CH=CH₂, but there is no experimental information concerning the distribution of isomers formed via Br addition to CH₂=C(CH₃)CH=CH₂. The rather large recommended uncertainty results from the somewhat indirect nature of the rate constant determination and the lack of a confirming study.

G48. Br + OCIO. The recommended value for k(298 K) is the mean of the values reported by Clyne and Watson¹ and Toohey.² In the study of Clyne and Watson, correction for the effect of the rapid reverse reaction was required. The temperature dependence reported by Toohey² is accepted but with increased error limits.

- G52. $\text{BrO} + \text{NO}$.** The results of three low pressure mass spectrometric studies (Clyne and Watson,² Ray and Watson,⁴ and Leu³) and a high pressure UV absorption study (Watson et al.⁵), which all used pseudo-first-order conditions, are in excellent agreement at 298 K and are thought to be much more reliable than an earlier low pressure UV absorption study (Clyne and Cruse¹). The results of the two temperature-dependent studies (Leu and Watson et al.) are in good agreement and both show a small negative temperature dependence. The preferred Arrhenius expression was derived from a least squares fit to all the data reported in the four studies mentioned above. By combining the data reported by Watson et al. with those from the three mass spectrometric studies, it can be shown that this reaction does not exhibit any observable pressure dependence between 1 and 700 Torr total pressure. The temperature dependences of k for the analogous ClO and HO₂ reactions are also negative and are similar in magnitude.

G54. BrO + ClO. Friedl and Sander,⁴ using DF/MS techniques, measured the overall rate constant over the temperature range 220–400 K and also over this temperature range determined branching ratios for the reaction channels producing BrCl and OCIO. The same authors in a separate study using flash photolysis–ultraviolet absorption techniques (Sander and Friedl⁷) determined the overall rate constant over the temperature range 220–400 K and pressure range 50–750 Torr and also determined the branching ratio for OCIO production at 220 K and 298 K. The results by these two independent techniques are in excellent agreement, with the overall rate constant showing a negative temperature dependence. Turnipseed et al.⁹ using DF/MS techniques also found a negative temperature dependence, reporting measurements of the overall rate constant and direct measurements of the branching ratios for the BrCl and OCIO channels. Several other studies have reported only room temperature values: Toohey and Anderson,⁸ using DF/RF/LMR techniques, reported room temperature values of the overall rate constant and the branching ratio for OCIO production. They also found evidence for the direct production of BrCl in a vibrationally excited Π state. Poulet et al.,⁶ using DF/MS techniques, reported room temperature values of the overall rate constant and branching ratios for OCIO and BrCl production. Overall room temperature rate constant values reported also include a result from the DF/MS study of Clyne and Watson² and a very low value derived in the flash photolysis study of Basco and Dogra.¹ The recommended Arrhenius expressions for the individual reaction channels are taken from the studies of Friedl and Sander⁴ and Turnipseed et al.⁹ These studies contain the most comprehensive sets of rate constant and branching ratio data. The overall rate constants reported in these two studies are in good agreement (20%) at room temperature and in excellent agreement at stratospheric temperatures. Both studies report that OCIO production by channel (1) accounts for 60% of the overall reaction at 200 K and that the BrCl yield by channel (3) is about 8%, relatively independent of temperature. The recommended expressions are consistent with the body of data from all older studies except those of Hills et al.⁵ and Basco and Dogra.¹ Recent results from Ferracci and Rowley³ using laser flash photolysis-absorption spectroscopy to measure the overall rate constant and branching ratio of the OCIO channel are substantially higher than the recommended values and include a positive temperature dependence for the branching ratio of the OCIO channel, in disagreement with past studies. Secondary chemistry is likely the cause of the discrepancies.

G55. BrO + BrO. Measurements of the overall rate constant can be divided into categories—those in which BrO was monitored by UV absorption and those in which BrO was monitored by mass spectrometry. Gilles et al.⁴ re-analyzed the results of the UV absorption studies and scaled the reported values of the rate constant to the UV absorption cross sections reported in their paper. When scaled in this manner, the room temperature rate constant values reported in the UV absorption studies (Sander and Watson,¹¹ Mauldin et al.,⁹ Bridier et al.,¹ Rowley et al.,¹⁰ Laszlo et al.,⁸ and Gilles et al.) come into very good agreement among themselves and also with results of the mass spectrometric studies of Clyne and Watson² and Lancar et al.⁷ This provides the basis for the recommended value for $k(298\text{ K})$. The temperature dependence is based on results of Sander

and Watson, Turnipseed et al.¹² and Gilles et al. The results of Harwood et al.⁵ are in good agreement with the recommendation.

There are two possible bimolecular channels for this reaction: $\text{BrO} + \text{BrO} \rightarrow 2\text{Br} + \text{O}_2$ (k_1) and $\text{BrO} + \text{BrO} \rightarrow \text{Br}_2 + \text{O}_2$ (k_2). The partitioning of the total rate constant into these two components, k_1 and k_2 , has been determined at room temperature by Sander and Watson,¹¹ Turnipseed et al.,¹² and Lancar et al.,⁷ by Jaffe and Mainquist⁶ from 258 to 333 K, by Cox et al.³ from 278 to 348 K, and by Mauldin et al.⁹ from 220 to 298 K. All are in agreement that $k_1/k = 0.85 \pm 0.03$ at 298 K. From the values of $k_1/k = 0.85$ at 298 K (all studies) and 0.68 at 220 K (Mauldin et al. and Cox et al. extrapolated), one can derive the temperature-dependent expression $k_1/k = 1.60 \exp(-190/T)$. From the recommended Arrhenius expression for the overall rate constant $k = k_1 + k_2$ and the expression for the branching ratio k_1/k , one can derive the following Arrhenius expressions for the individual reaction channels:

$$k_1 = 2.4 \times 10^{-12} \exp(40/T) \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$$

$$k_2 = 2.8 \times 10^{-14} \exp(860/T) \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$$

G56. OBrO + O₃. The upper limit for k (298 K) was determined by Li et al.¹ using DF/MS.

(Table: 10-6, Note: 10-6, Evaluated: 10-6) [Back to Table](#)

- (1) Li, Z. J.; Jeong, G. R.; Person, E. Kinetics of reactions of OBrO with NO, O₃, OClO, and ClO at 240-350 K. *Int. J. Chem. Kinet.* **2002**, 34, 430-437, doi:10.1002/kin.10069.

G57. OBrO + NO. The recommended Arrhenius parameters are those determined by Li et al.¹ using DF/MS to monitor the decay of OBrO in excess NO. A possible complication in these experiments exists from the secondary reaction of Br with OBrO.

(Table: 10-6, Note: 10-6, Evaluated: 10-6) [Back to Table](#)

- (1) Li, Z. J.; Jeong, G. R.; Person, E. Kinetics of reactions of OBrO with NO, O₃, OClO, and ClO at 240-350 K. *Int. J. Chem. Kinet.* **2002**, 34, 430-437, doi:10.1002/kin.10069.

G58. CH₂BrO₂ + NO. The recommended value for k (298 K) is based on the 298 K measurement of Sehested et al.,⁴ who used pulsed radiolysis with UV absorption detection of the NO₂ product formation rate. The temperature dependence is estimated based on analogy to similar RO₂ + NO reactions. The CH₂BrO product

has been shown to undergo rapid unimolecular decomposition to yield $\text{CH}_2\text{O} + \text{Br}$ by Chen et al.¹ and Orlando et al.³ The domination of this channel over the reaction of CH_2BrO with O_2 is consistent with the fate of other alkoxy radicals (Chen et al. and Orlando et al.), but contradicts the earlier result of Nielson et al.² (Table: 94-26, Note: 97-4, Evaluated: 97-4) [Back to Table](#)

1.13 IO_x Reactions

1.13.1 Table 1H: IO_x Reactions

Reaction	Temperature Range of Exp. Data (K) ^a	A-Factor	E/R	k(298 K) ^b	f(298 K) ^c	g	Notes
O + I ₂ → IO + I	298	1.4×10 ⁻¹⁰	0	1.4×10 ⁻¹⁰	1.4	250	H 1
O + IO → O ₂ + I	298			1.2×10 ⁻¹⁰	2.0		H 2
OH + I ₂ → HOI + I	294–298			1.8×10 ⁻¹⁰	2.0		H 3
OH + HI → H ₂ O + I	298			3.0×10 ⁻¹¹	2.0		H 4
OH + CH ₃ I → H ₂ O + CH ₂ I	271–423	2.9×10 ⁻¹²	1100	7.2×10 ⁻¹⁴	1.5	300	H 5
OH + CF ₃ I → HOI + CF ₃	271–450	2.5×10 ⁻¹¹	2070	2.4×10 ⁻¹⁴	1.3	200	H 6
HO ₂ + I → HI + O ₂	283–353	1.5×10 ⁻¹¹	1090	3.8×10 ⁻¹³	2.0	500	H 7
HO ₂ + IO → products	273–373	1.3×10 ⁻¹¹	–570	8.8×10 ⁻¹¹	1.15	100	H 8
NO ₃ + HI → HNO ₃ + I		(See Note)					H 9
Cl + CH ₃ I → CH ₂ I + HCl	273–363	2.9×10 ⁻¹¹	1000	1.0×10 ⁻¹²	1.5	250	H10
I + O ₃ → IO + O ₂	231–337	2.3×10 ⁻¹¹	870	1.2×10 ⁻¹²	1.2	200	H11
I + NO $\xrightarrow{M}$ INO		(See Table 2-1)					
I + NO ₂ $\xrightarrow{M}$ INO ₂		(See Table 2-1)					
I + BrO → IO + Br	298			1.2×10 ⁻¹¹	2.0		H12
IO + NO → I + NO ₂	240–370	9.1×10 ⁻¹²	–240	2.0×10 ⁻¹¹	1.2	150	H13
IO + NO ₂ $\xrightarrow{M}$ IONO ₂		(See Table 2-1)					
IO + ClO → products	200–362	5.1×10 ⁻¹²	–280	1.3×10 ⁻¹¹	2.0	200	H14
IO + BrO → products	204–388			6.9×10 ⁻¹¹	1.5		H15
IO + IO → products	250–373	1.5×10 ⁻¹¹	–500	8.0×10 ⁻¹¹	1.5	500	H16
INO + INO → I ₂ + 2NO	320–450	8.4×10 ⁻¹¹	2620	1.3×10 ⁻¹⁴	2.5	600	H17
INO ₂ + INO ₂ → I ₂ + 2NO ₂	320–450	2.9×10 ⁻¹¹	2600	4.7×10 ⁻¹⁵	3.0	1000	H18

Shaded areas indicate changes or additions since JPL10-6.

^a Temperature range of available experimental data. This is not necessarily the range of temperature over which the recommended Arrhenius parameters are applicable. See the corresponding note for each reaction for such information.

^b Units are cm³ molecule⁻¹ s⁻¹.

^c f(298 K) is the uncertainty factor at 298 K. To calculate the uncertainty at other temperatures, use the expression:

$$f(T) = f(298 \text{ K}) \exp \left| g \left(\frac{1}{T} - \frac{1}{298} \right) \right|$$

Note that the exponent is an absolute value.

1.13.2 Notes: IO_x Reactions

- H1. O + I₂.** Based on the room temperature data of Ray and Watson³ and Laszlo et al.¹ The molecular beam study of Parrish and Herschbach² suggests a zero activation energy, consistent with the near gas kinetic value of *k* at 298 K.
(Table: 97-4, Note: 97-4, Evaluated: 97-4) [Back to Table](#)

- H2. O + IO.** Based on results of Laszlo et al.,¹ the only reported study of this rate constant. This value was derived from modeling a system in which the concentrations of I₂ and IO were monitored simultaneously. This rate constant is a factor of 4 greater than the values for the corresponding reactions of O with ClO and BrO.

H7. HO₂ + I. Based on the data of Jenkin et al.,¹ the only reported study of this reaction.

(Table: 94-26, Note: 94-26, Evaluated: 94-26) [Back to Table](#)

- (1) Jenkin, M. E.; Cox, R. A.; Mellouki, A.; Le Bras, G.; Poulet, G. Kinetics of the reaction of iodine atoms with HO₂ radicals. *J. Phys. Chem.* **1990**, *94*, 2927-2934, doi:10.1021/j100370a036.

H8. HO₂ + IO. The recommended value for k(298 K) is the average of values obtained from the Arrhenius expressions reported by Cronkhite et al. (274–373 K)² and Knight and Crowley (273–353 K).⁵ The recommended room temperature uncertainty limits encompass the results of Maguin et al.⁶ and Canosa-Mas et al.¹ and overlap with the uncertainty interval reported by Jenkin et al.⁴ The recommended E/R is obtained from a weighted fit (1/k² weighting factors) of the combined data of Cronkhite et al. and Knight and Crowley (one average rate constant per temperature studied) to the Arrhenius equation after scaling each individual set of rate constants by a constant factor so that the Arrhenius expressions describing the individual data sets each give the recommended k(298 K). In low pressure (~1 Torr He) flow tube studies, both Knight and Crowley and Maguin et al. observe HOI as a reaction product, but a quantitative HOI yield has not been reported. Computational results by Drougas and Kosmas³ confirm the existence of energetically favorable pathways to HOI + O₂(¹Δ) products via both HOOIO and HOOOI intermediates. Drougas and Kosmas also predict that HOOIO can isomerize to the very stable HOIO₂ species (bound by ~220 kJ mol⁻¹ relative to IO + HO₂). The predicted transition states for HOOIO isomerization and dissociation are approximately equal in energy to each other and to the HO₂ + IO reactants.

H9. NO₃ + HI. No recommendation is given, based on the potential for severe complications resulting from secondary chemistry in the only reported study of the reaction (Lancar et al.¹).

(Table: 94-26, Note: 94-26, Evaluated: 94-26) [Back to Table](#)

- (1) Lancar, I.; Mellouki, A.; Poulet, G. Kinetics of the reactions of hydrogen iodide with hydroxyl and nitrate radicals. *Chem. Phys. Lett.* **1991**, *177*, 554-558, doi:10.1016/0009-2614(91)90083-L.

H10. Cl + CH₃I. This reaction, thought to be a simple H abstraction reaction, has been shown by Ayhens et al.¹ to be quite complex. At low temperatures, Cl atom reversibly adds to CH₃I to form CH₃ICl. Thus, there are at least two channels for this reaction,

The rate coefficient for channel (a) has been measured by Ayhens et al. above 364 K, Kambanis et al.⁵ between 273 and 363 K, Bilde and Wallington² at 298 K, and Cotter et al.³ at 298 K. The recommendation is based on these studies.

Under atmospheric conditions reaction (b) to form the adduct is about two orders of magnitude faster than reaction (a). However, the fate of the CH₃ICl adduct in the atmosphere is unclear. Its lifetime, based on the

studies of Ayhens et al., can be as long as a few seconds at 200 K and a few hundred Torr pressure. Therefore, it is possible that it could react with O₂ or be photolyzed. At 298 K, in one atmosphere of O₂, it appears that the overall fate of the CH₃ClI is to decompose back to the reactants, based on the work of Bilde and Wallington.² Therefore, if O₂ were to react with CH₃ICl, this rate coefficient has to be less than about 10⁻¹⁷ cm³ molecule⁻¹ s⁻¹, using the rate coefficient for its decomposition measured by Ayhens et al. If the rate coefficient for CH₃ICl + O₂ were to remain approximately the same, i.e., 10⁻¹⁷ cm³ molecule⁻¹ s⁻¹, at lower temperatures, the possible loss of CH₃ICl via reaction with O₂ cannot be ignored. Further, the possible atmospheric photolysis of CH₃ICl may be important if it has a J-value greater than 0.1 s⁻¹.

There is a third possible product channel for this reaction to yield CH₃Cl + I (Goliff and Rowland⁴). Based on the results of Bilde and Wallington and Goliff and Rowland, we recommend that the rate coefficient for the Cl + CH₃I → CH₃Cl + I reaction to be less than 0.2k_a at 298 K. Since such a reaction is likely to have a significant barrier in the gas phase, even though it is exothermic by ~14 kcal mol⁻¹ at 298 K, the branching ratio for the production of CH₃Cl and I in the atmosphere will be likely less than that at 298 K.

- H14. IO + ClO.** Based on results of Turnipseed et al.,¹ the only reported study of this reaction. These authors also reported the product yield for channel(s) yielding an I atom to be 0.8 ± 0.2 .
(Table: 97-4, Note: 97-4, Evaluated: 97-4) [Back to Table](#)
- (1) Turnipseed, A. A.; Gilles, M. K.; Burkholder, J. B.; Ravishankara, A. R. Kinetics of the IO radical. 1. Reaction of IO with ClO. *J. Phys. Chem. A* **1997**, 101, 5517-5525, doi:10.1021/jp970914g.
- H15. IO + BrO.** Based primarily on results of Laszlo et al.² Gilles et al.¹ reported the following Arrhenius expression for non-iodine atom producing channels: $2.5 \times 10^{-11} \exp(260/T) \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$. They also reported a branching ratio of <0.35 for channels producing I atoms. From their data they could constrain the value of the overall rate constant to be: $6 \times 10^{-11} < k < 10 \times 10^{-11} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$, the range of which is consistent with the results of Laszlo et al.

- H16. IO + IO.** Sander³ reported a negative temperature dependence over the temperature range 250–373 K for the overall rate constant and for the absorption cross section at 427.2 nm. Harwood et al.¹ reported that the overall rate constant and the absorption cross section to be independent of temperature from 253 to 320 K. The recommended room temperature value is the average of the values reported by Sander, Harwood et al., and Laszlo et al.² The recommended temperature dependence is the average of the values reported by Sander and by Harwood et al., with an uncertainty sufficient to encompass the two reported values. The A-factor has been fitted to the recommended room temperature rate constant and the recommended temperature dependence. The overall rate constant for the decay of IO in the absence of ozone has been found to be independent of pressure by Sander, Laszlo et al., and Harwood et al. A comparison of the overall rate observed in excess ozone to that in the absence of ozone was interpreted by Sander and by Harwood et al. to imply that formation of the dimer I_2O_2 is the dominant reaction channel in the IO self-reaction.

1.14 SO_x Reactions

1.14.1 Table 1I: SO_x Reactions

Reaction	Temperature Range of Exp. Data (K) ^a	A-Factor	E/R	k(298 K) ^b	f(298 K) ^c	g	Note
$O + SH \rightarrow SO + H$	295			1.6×10^{-10}	5.0		I1
$O + CS \rightarrow CO + S$	150–305	2.7×10^{-10}	760	2.1×10^{-11}	1.1	250	I2
$O + H_2S \rightarrow OH + SH$	205–502	9.2×10^{-12}	1800	2.2×10^{-14}	1.7	550	I3
$O + OCS \rightarrow CO + SO$	239–808	2.1×10^{-11}	2200	1.3×10^{-14}	1.15	150	I4
$O + CS_2 \rightarrow CS + SO$	218–543	3.2×10^{-11}	650	3.6×10^{-12}	1.2	150	I5
$O + SO_2 \xrightarrow{M} SO_3$		(See Table 2-1)					
$O + CH_3SCH_3 \rightarrow CH_3SO + CH_3$	252–557	1.3×10^{-11}	–410	5.0×10^{-11}	1.1	100	I6
$O + CH_3SSCH_3 \rightarrow CH_3SO + CH_3S$	270–571	3.9×10^{-11}	–290	1.03×10^{-10}	1.1	100	I7
$O + CH_3S(O)CH_3 \rightarrow \text{products}$	266–383	2.0×10^{-12}	–440	8.8×10^{-12}	1.2	200	I8
$O_3 + H_2S \rightarrow \text{products}$	~298			$< 2.0 \times 10^{-20}$			I9
$O_3 + CH_3SCH_3 \rightarrow \text{products}$	301			$< 1.5 \times 10^{-19}$			I10
$O_3 + SO_2 \rightarrow SO_3 + O_2$	300	3.0×10^{-12}	>7000	$< 2.0 \times 10^{-22}$			I11
$O_3 + SO_2F_2 \rightarrow \text{products}$	294–296			$< 1.0 \times 10^{-23}$			I12
$OH + H_2S \rightarrow SH + H_2O$	228–518	6.1×10^{-12}	75	4.7×10^{-12}	1.1	75	I13
$OH + OCS \rightarrow \text{products}$	255–517	7.2×10^{-14}	1070	2.0×10^{-15}	1.5	200	I14
$OH + CS_2 \rightarrow SH + OCS$	251–520			$< 2.0 \times 10^{-15}$			I15
$OH + CS_2 \rightarrow CS_2OH \xrightarrow{O_2} \text{products}$		(See Note)		1.2×10^{-12} at $P_{\text{air}} = 1 \text{ atm}$	1.25		I16
$CS_2OH + O_2 \rightarrow \text{products}$	249–348	2.8×10^{-14}	0	2.8×10^{-14}	1.2	100	I17
$OH + CH_3SH \rightarrow CH_3S + H_2O$	244–430	9.9×10^{-12}	–360	3.3×10^{-11}	1.07	75	I18
$OH + CH_3SCH_3 \rightarrow H_2O + CH_2SCH_3$	248–573	1.2×10^{-11}	280	4.7×10^{-12}	1.1	100	I19
$OH + CH_3SCH_3 \xrightarrow{M} (CH_3)_2SOH \xrightarrow{O_2} \text{products}$		(See Note)		2.0×10^{-12} at $P_{\text{air}} = 1 \text{ atm}$	1.2		I20
$(CH_3)_2SOH + O_2 \rightarrow \text{products}$	222–297	8.5×10^{-13}	0	8.5×10^{-13}	1.25	0	I21
$OH + CH_3SCH_2Cl \rightarrow \text{products}$	298			2.5×10^{-12}	2.0		I22

Reaction	Temperature Range of Exp. Data (K) ^a	A-Factor	E/R	k(298 K) ^b	f(298 K) ^c	g	Note
OH + CH ₃ SSCH ₃ → products	249–368	6.0×10 ⁻¹¹	-400	2.3×10 ⁻¹⁰	1.2	200	I23
OH + CH ₃ S(O)CH ₃ → products	298–401	6.1×10 ⁻¹²	-800	8.9×10 ⁻¹¹	1.2	500	I24

Shaded areas indicate changes or additions since JPL10-6.

^a Temperature range of available experimental data. This is not necessarily the range of temperature over which the recommended Arrhenius parameters are applicable. See the corresponding note for each reaction for such information.

^b Units are cm³ molecule⁻¹ s⁻¹.

^c f(298 K) is the uncertainty factor at 298 K. To calculate the uncertainty at other temperatures, use the expression:

$$f(T) = f(298\text{ K}) \exp \left| g \left(\frac{1}{T} - \frac{1}{298} \right) \right|$$

Note that the exponent is an absolute value.

1.14.2 Notes: SO_x Reactions

- I1. O + SH.** This recommendation accepts the results of Cupitt and Glass.¹ The large uncertainty reflects the absence of any confirming investigation.
(Table: 82-57, Note: 82-57, Evaluated: 82-57) [Back to Table](#)
- (1) Cupitt, L. T.; Glass, G. P. Reactions of SH with atomic oxygen and hydrogen. *Int. J. Chem. Kinet.* **1975**, *Symp. 1*, 39-50.
- I2. O + CS.** The room temperature recommendation is an average of the rate constants determined by Slagle et al.,⁴ Bida et al.,¹ Lilenfeld and Richardson,³ and Hancock and Smith.² The temperature dependence is that of Lilenfeld and Richardson, with the A-factor adjusted to yield the recommended value of $k(298\text{ K})$.
(Table: 94-26, Note: 94-26, Evaluated: 94-26) [Back to Table](#)

- I3. O + H₂S.** This recommendation is derived from an un-weighted least-squares fit of the data of Singleton et al.⁴ and Whytock et al.⁸ The results of Slagle et al.⁶ show very good agreement for E/R in the temperature region of overlap (300–500 K) but lie systematically higher at every temperature. The uncertainty factor at 298 K has been chosen to encompass the room temperature rate constant values of Slagle et al.⁶ and Hollinden et al.³ Other than the 263 K data point of Whytock et al. and the 281 K point of Slagle et al., the main body of rate constant data below 298 K comes from the study of Hollinden et al., which indicates a dramatic change in E/R in this temperature region. Thus, the parameter g was set to account for these observations. Such a non-linearity in the Arrhenius plot might indicate a change in the reaction mechanism from abstraction (as written) to addition. An addition channel (resulting in H atom displacement) has been proposed by Slagle et al.,⁶ Singleton et al.,⁴ and Singleton et al.⁵ In the latter two studies, an upper limit of 20% was placed on the displacement channel. Direct observations of product HSO were made in the reactive scattering experiments of Clemo et al.¹ and Davidson et al.² A threshold energy of 3.3 kcal/mole was observed (similar to the activation energy measured in earlier studies), suggesting the importance of this direct displacement channel. Addition products from this reaction have been seen in a matrix by Smardzewski and Lin.⁷ Further kinetic studies in the 200–300 K temperature range, as well as quantitative direct mechanistic information, could clarify these issues.

- 14. O + OCS.** The value of $k(298\text{ K})$ is the average of the determinations by Westenberg and de Haas,¹⁰ Klemm and Stief,⁵ Wei and Timmons,⁹ Manning et al.,⁶ and Breckenridge and Miller.¹ The recommended value of E/R is the average value taken from the first three listed studies. Hsu et al.⁴ report that this reaction proceeds exclusively by a stripping mechanism. The vibrational and rotational state distributions in the SO and CO products have been reported by Chen et al.² and Nickolaissen et al.,⁷ respectively. The kinetic isotope effect $k(^{34}\text{S})/k(^{32}\text{S})$ was reported by Hattori et al.³ to be 0.9783 ± 0.0062 at 298 K. A theoretical calculation of potential energy surfaces and T-dependent rate coefficients (200–2500 K) has been reported by Saheb et al.⁸ (Table: 06-2, Note: 15-10, Evaluated: 06-2) [Back to Table](#)

- 15. O + CS₂.** The value of $k(298\text{ K})$ is an average of the rate constants determined by Wei and Timmons,⁹ Westenberg and de Haas,¹⁰ Slagle et al.,⁸ Callear and Smith,³ Callear and Hedges,² Homann et al.,⁶ Borissenko et al.,¹ and Graham and Gutman.⁵ The E/R value is an average of the determinations by Wei and Timmons and Graham and Gutman. The g value has been set to encompass the temperature-dependent data of Westenberg and deHaas. The principal reaction products are thought to be CS + SO. However, Hsu et al.⁷ report that 1.4% of the reaction at 298 K proceeds through a channel yielding $\text{CO} + \text{S}_2$ and calculate a rate constant for the overall process in agreement with that recommended. Graham and Gutman⁵ have found that 9.6% of the reaction proceeds to yield $\text{OCS} + \text{S}$ at room temperature. Using time-resolved diode laser spectroscopy, Cooper and Hershberger⁴ determined the branching ratios for the CO- and OCS-producing channels to be $(3.0 \pm 1.0)\%$ and $(8.5 \pm 1.0)\%$, respectively. - 16. O + CH₃SCH₃.** This recommendation is based on a fit of the data from Nip et al.,⁴ Lee et al.,³ and Lee et al.² Product studies by Cvetanovic et al.¹ indicate that the reaction proceeds almost entirely by addition followed by rapid fragmentation to the products as written. Pavanaja et al.⁵ examined the pressure and reactant ratio dependencies of OH(A²Σ⁺) and SO₂(³B, ¹B) emissions in this reaction system. Their observations are consistent with initial product formation as written, followed by secondary generation of both OH and SO₂. (Table: 94-26, Note: 97-4, Evaluated: 94-26) [Back to Table](#)

- 17. O + CH₃SSCH₃.** This recommendation averages the 298 K rate constants of Nip et al.⁴ and Borissenko et al.,¹ which are in good agreement with each other, but are about a factor of 2 slower than the value reported by Lee et al.³ The recommendation for E/R has been obtained from an un-weighted Arrhenius fit that employs all available data, but scales the data of Lee et al. downward by a factor of 2.04 to bring their data into agreement with the other data at room temperature. Product studies by Cvetanovic et al.² indicate that the reaction proceeds mainly by addition followed by rapid fragmentation to the products as written. Pavanaja et al.⁵ examined the pressure and reactant ratio dependencies of OH(A²Σ⁺) and SO₂(³B, ¹B) emissions in this reaction system. Their observations are consistent with initial product formation as written, followed by secondary generation of both OH and SO₂. (Table: 06-2, Note: 06-2, Evaluated: 06-2) [Back to Table](#)

- 18. O + CH₃S(O)CH₃.** The recommended 298 K rate constant is the average of values reported from a laser flash photolysis – resonance fluorescence study by Pope et al.,² and from a discharge flow – mass spectrometry study by Riffault et al.³ A rate constant reported by Barnes et al.¹ (with no details about how the rate constant was obtained) is somewhat faster than the recommendation, but in agreement to within the recommended uncertainty factor. The recommended value for E/R is from Pope et al. The recommended value for the parameter g is larger than the value reported by Pope et al. to reflect the fact that only a single

temperature dependence study has been reported. In their study at one Torr total pressure, Riffault et al. found that the products $\text{SO}_2 + 2 \text{CH}_3$ are produced with near unit yield.

- I10. $\text{O}_3 + \text{CH}_3\text{SCH}_3$.** The recommendation is based on the study of Du et al.¹ which gives a more sensitive upper limit than an earlier study by Martinez and Herron.² Du et al. used cyclohexane to scavenge OH radicals and high levels of O_2 to scavenge oxygen atoms and convert more reactive carbon-centered radicals to less reactive peroxy radicals. Their reported rate constant is $(1.04 \pm 0.21) \times 10^{-19} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$. Because of the potential for interference from wall reaction or reactions involving radicals generated via secondary chemistry, the recommendation is an upper limit equal to the rate constant reported by Du et al. plus twice its reported uncertainty.

Technol.* **2009**, *43*, 1067-1070, doi:10.1021/es802439f.

- I13. $\text{OH} + \text{H}_2\text{S}$.** The values of $k(298 \text{ K})$ and E/R are derived from a composite un-weighted least-squares fit to the individual data points of Perry et al.,¹⁰ Cox and Sheppard,³ Wine et al.,¹⁶ Leu and Smith,⁶ Michael et al.,⁹ Lin,⁷ Lin et al.,⁸ Wang and Lee,¹³ Barnes et al.,¹ Lafage et al.,⁵ and Wang et al.¹² The studies of Leu and Smith,⁶ Lin et al.,⁸ Lin,⁷ and Lafage et al.⁵ show a slight parabolic temperature dependence of k with a minimum occurring near room temperature. However, with the error limits stated in this evaluation, all data are fit reasonably well by an Arrhenius expression. Lafage et al. and Michael et al. discuss the results in

terms of a two-channel reaction scheme involving direct H atom abstraction and complex (adduct) formation. Lafage et al. analyzed their results above room temperature to yield an apparent $E/R = 400$ K for the abstraction channel, in good agreement with the E/R value determined above room temperature by Westenberg and de Haas.^{14,15} The results of these latter workers lie systematically higher (by about 70%), presumably due to secondary reactions. The room temperature value measured by Stuhl¹¹ lies just outside the 2σ error limit set for $k(298\text{ K})$. Theoretical work by Ellingson and Truhlar⁴ supports the non-Arrhenius temperature dependence reported by some investigators (see above); they attribute the unusual temperature dependence to “a dynamical bottleneck at an energy below reactants, following an addition complex on the reaction path with a classical binding energy of 4.4 kcal/mol.” Butkovskaya and Setser² have observed infrared emission from vibrationally excited levels of the expected reaction product H_2O .

I14. OH + OCS. The recommendation is based on the 298 K study of Wahner and Ravishankara¹⁰ and the temperature dependent (255–483 K) study of Cheng and Lee.² Because the data of Cheng and Lee suggest slight curvature in the Arrhenius plot, only their data at $T \leq 423$ K were used to arrive at the recommended Arrhenius parameters. The room temperature rate constants from the above-mentioned studies are a factor of 3 higher than the earlier determination by Leu and Smith.⁷ As discussed in the later studies, this difference may be due to an overcorrection of the Leu and Smith data to account for OH reaction with H_2S impurities and also to possible regeneration of OH. The work by Wahner and Ravishankara¹⁰ supersedes the study of Ravishankara et al.⁸ The Wahner and Ravishankara study minimized complications due to secondary and/or excited state reactions that presumably were interfering with the experiments of Atkinson et al.¹ and Kurylo.⁵

The upper limit for $k(298\text{ K})$ reported by Cox and Sheppard³ is too insensitive to permit comparison with the more recent studies. The room temperature measurements of Wahner and Ravishankara demonstrate the lack of an effect of total pressure (or O_2 partial pressure) on the rate constant and are supported by the more limited pressure- and O_2 -dependent studies of Cheng and Lee. A theoretical calculation of potential energy surfaces and T-dependent rate coefficients (200–2500 K) has been reported by Saheb et al.⁹

Product observations by Leu and Smith indicate that SH is a primary product of this reaction and tentatively confirm the suggestion of Kurylo and Laufer⁶ that the predominant reaction pathway is to produce $\text{SH} + \text{CO}_2$ through a complex (adduct) mechanism similar to that observed for the $\text{OH} + \text{CS}_2$ reaction. However, the absence of an O_2 /pressure effect for $\text{OH} + \text{OCS}$ is in marked contrast with the strong dependence seen in studies of $\text{OH} + \text{CS}_2$ (see note for the latter reaction).

Experiments by Greenblatt and Howard⁴ have shown that oxygen atom exchange in the reaction of ^{18}OH with OCS is relatively unimportant, leading to an upper limit of $10^{-15}\text{ cm}^3\text{ molecule}^{-1}\text{ s}^{-1}$ for the rate constant of the exchange reaction.

- I15. $\text{OH} + \text{CS}_2 \rightarrow \text{SH} + \text{OCS}$.** There is a consensus of experimental evidence that this reaction proceeds very slowly as a direct bimolecular process. Wine et al.⁸ set an upper limit on $k(298\text{ K})$ of $1.5 \times 10^{-15}\text{ cm}^3\text{ molecule}^{-1}\text{ s}^{-1}$. A consistent upper limit is also reported by Iyer and Rowland⁴ for the rate of direct production of OCS , suggesting that OCS and SH are primary products of the bimolecular process. This mechanistic interpretation is further supported by the studies of Leu and Smith⁶ and Biermann et al.,² which set somewhat higher upper limits on $k(298\text{ K})$. The more rapid reaction rates measured by Atkinson et al.,¹ Kurylo,⁵ and Cox and Sheppard³ may be attributable to severe complications arising from excited state and secondary chemistry in their photolytic systems. The Cox and Sheppard study in particular may have been affected by the reaction of electronically excited CS_2 (produced via the 350 nm photolysis) with O_2 (in the 1-atm synthetic air mixture) as well as by the accelerating effect of O_2 on the $\text{OH} + \text{CS}_2$ reaction itself, which has been observed by other workers as summarized below. The possible importance of electronically excited CS_2 reactions in the tropospheric oxidation of CS_2 to OCS has been discussed by Wine et al.⁷

I16. OH + CS₂ → CS₂OH^{O₂} products. An accelerating effect of O₂ on the OH + CS₂ reaction rate has been observed by Jones et al.,³ Barnes et al.,¹ and Hynes et al.,² along with a near unity product yield for SO₂ and OCS. In the latter two studies the effective bimolecular rate constant was found to be a function of total pressure (O₂ + N₂), and exhibited an appreciably negative temperature dependence. These observations are consistent with the formation of a long-lived adduct as postulated by Kurylo⁴ and Kurylo and Laufer⁵ followed by its reaction with O₂:

The effective second order rate constant for CS₂ or OH removal in the above reaction scheme can be expressed as

$$1/k_{\text{eff}} = (k_b/k_a k_c)(1/P_{\text{O}_2}) + (1/k_a)(1/P_{\text{M}})$$

where P_{O₂} is the partial pressure of O₂ and P_M equals P_{O₂} + P_{N₂}. The validity of this expression requires that k_a and k_b are invariant with the P_{O₂}/P_{N₂} ratio. A 1/k vs 1/P_{O₂} plot of the data of Jones et al.³ taken at atmospheric pressure exhibits marked curvature, suggesting a more complex mechanistic involvement of O₂, whereas the data of Barnes et al.¹ and Hynes et al.² are more satisfactorily represented by this analytical expression. Nevertheless, while the qualitative features of the data from all three laboratories agree, there are some quantitative inconsistencies. First, under similar conditions of O₂ and N₂ pressures, the Barnes et al. rate constants lie approximately 60% higher than those of Jones et al. and up to a factor of 2 higher than those derived by Hynes et al. Secondly, two fits each of both the Barnes et al. and Hynes et al. data can be made: one at fixed P_M and varying P_{O₂}, and the other at fixed P_{O₂} and varying P_M (i.e., varying added N₂). Within each data set, rate constants calculated from both fits agree reasonably well for mole fractions of O₂ near 0.2 (equivalent to air) but disagree by more than a factor of 2 for measurements in a pure O₂ system. Finally, the temperature dependence (from 264–293 K) of the k_{eff} values from Barnes et al. varies systematically from an E/R of –1300 K for experiments in pure O₂ (at 700 Torr total pressure) to –2900 K for experiments in a 50 Torr O₂ plus 650 Torr N₂ mixture. An Arrhenius fit of the Hynes et al. data (from 251–348 K) recorded in synthetic air at 690 Torr yields an E/R = –3300 K, although the data show marked curvature over the temperature range of study. These observations suggest that k_a and k_b may not be independent of the identity of M. For this reason, we limit our recommendation to air mixtures (i.e., P_{O₂}/P_{N₂} = 0.25) at atmospheric pressure. Since most CS₂ is oxidized within the atmospheric boundary layer, such restriction does not limit the applicability of this recommendation in atmospheric modeling.

The present recommendation accepts the measurements of Hynes et al.,² which appear to be the most sensitive of the three investigations. Thus, k(298 K) is derived from the Arrhenius fit of the data near room temperature.

$$k(298 \text{ K}) = 1.2 \times 10^{-12} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$$

To compute values of k below 298 K, we have accepted the analysis of Hynes et al.:

$$k(T) = (1.25 \times 10^{-16} \exp(4550/T))/(T + 1.81 \times 10^{-3} \exp(3400/T)) \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}.$$

This recommendation is only valid for one atmosphere pressure of air. It is interesting to note that measurements by Hynes et al.² at approximately 250 K and 700 Torr total pressure result in k_{eff} values that are independent of the amount of O₂ for partial pressures between 145 and 680 Torr. This suggests that the adduct is quite stable with respect to dissociation into the reactants (OH + CS₂) at this low temperature and that the effective rate constant for reactant removal approaches the elementary rate constant for adduct formation.

I17. $\text{CS}_2\text{OH} + \text{O}_2$. Three groups have obtained kinetic information about this reaction by observing either the perturbation of OH/ CS_2OH equilibration kinetics upon addition of O_2 , or by modeling the dependence of the observed rate constant for OH loss on $[\text{O}_2]$. Hynes et al.,² Murrells et al.,⁷ and Diau and Lee¹ agree quite well on the value of k , with an average value of $2.8 \times 10^{-14} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ independent of temperature and pressure being recommended. Diau and Lee also report rate constants for the reactions of the adduct (CS_2OH) with NO and NO_2 to be 7.3×10^{-13} and $4.2 \times 10^{-11} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$, respectively.

From a mechanistic viewpoint, the primary products of this reaction determine the products of CS_2 oxidation in air. Lovejoy et al.⁴ have shown that the yields of HO_2 and SO_2 are equal and near unity. Further insight is provided by the mechanistic study of Stickel et al.,⁸ who observe OCS and CO product yields of (0.83 ± 0.08) and (0.16 ± 0.03) , respectively. The results from this study are interpreted to imply that OCS and CO are formed either as primary products of the $\text{CS}_2\text{OH} + \text{O}_2$ reaction or as products of a secondary reaction between a primary product and O_2 . These same authors report an SO_2 yield of (1.15 ± 0.10) , with the results suggesting that only about 75% of the SO_2 is formed as a prompt product, with the remainder generated via a slow reaction of SO (generated as a prompt product of the $\text{CS}_2\text{OH} + \text{O}_2$ reaction) with O_2 . Insight into the specific reaction pathways can be gleaned from the study of Lovejoy et al.³ in which the rate constant for the reaction of $\text{CS}_2\text{OD} + \text{O}_2$ was found to be the same as that for $\text{CS}_2\text{OH} + \text{O}_2$, indicating that simple H atom abstraction is not the likely process. Rather, HO_2 production most likely involves complex formation followed by HO_2 elimination. Lovejoy et al.⁵ found that the ^{18}O atom in the ^{18}OH reactant is transferred predominantly $(90 \pm 20)\%$ to the SO_2 product. These findings are consistent with an S-O-bonded $\text{CS}_2\text{-OH}$ adduct and preservation of the S-O bond in the steps leading to SO_2 formation.

Theoretical studies by Zhang and Qin⁹ and by McKee and Wine⁶ have provided further insight into the reaction mechanism. The initial step is, indeed, formation of SCS-OH followed by addition of O_2 to the carbon atom. A key subsequent step appears to be an O atom transfer to the sulfur bearing the hydroxyl group which leads directly to $\text{HOSO} + \text{OCS}$. The reaction $\text{HOSO} + \text{O}_2 \rightarrow \text{HO}_2 + \text{SO}_2$ is expected to occur rapidly under atmospheric conditions. One remaining problem is identification of the pathway for generation of CO, which is observed as a minor product.

118. OH + CH₃SH. This recommendation is based on a composite fit to the data of Atkinson et al.,¹ Wine et al.,¹⁰ Wine et al.,¹¹ and Hynes and Wine,⁵ which are in excellent agreement. The results from the relative rate study of Barnes et al.² are in agreement with this recommendation and indicate that the higher value of Cox and Sheppard⁴ is due to complications resulting from the presence of O₂ and NO in their reaction system. MacLeod et al.^{7,8} and Lee and Tang⁶ obtained rate constants at 298 K approximately 50% lower than recommended here. These authors also obtained lower values for the ethanethiol reaction in comparison with results from studies upon which the methanethiol recommendation is made. Wine et al.¹¹ present evidence that this reaction proceeds via adduct formation to produce a species that is thermally stable over the temperature range and time scales of the kinetic measurements. Tyndall and Ravishankara⁹ have determined the yield of CH₃S (via laser-induced fluorescence) to be unity, indicating that any adduct must be short lived (less than 100 μs). Longer lifetimes would have led to anomalies in the OH decay kinetics used for the rate constant determinations. Butkovskaya and Setser,³ based on observations of IR emissions from the products of the reactions of OH and OD with CH₃SH and CH₃SD, conclude that H-abstraction from the methyl group occurs with a yield of 24 ± 8% for the OH reactions and 11 ± 4% for the OD reactions. Hynes and Wine⁵ observed that the rate constant is independent of O₂ partial pressure.

119. OH + CH₃SCH₃ → H₂O + CH₂SCH₃. The OH + CH₃SCH₃ reaction is complex, proceeding by both H-abstraction and reversible addition pathways. In the presence of atmospheric levels of O₂, adduct reaction with O₂ makes the addition pathway partially irreversible. Only kinetic data obtained in the absence of O₂ and at low enough CH₃SCH₃ concentrations for the adduct to be a negligible reservoir for OH are considered in evaluation of the H-abstraction rate constant. Thus, this recommendation is based on the results of Hynes et al.,⁸ Wine et al.,²² Hsu et al.,⁷ Abbatt et al.,¹ Barone et al.,⁶ Turnipseed et al.,¹⁵ Williams et al.,¹⁹⁻²¹ and Wang et al.¹⁸ The earlier larger rate constant values of Atkinson et al.³ and Kurylo¹⁰ are presumably due to reactive impurities, while those of MacLeod et al.¹¹ were most likely overestimated because of heterogeneous reactions. Unlike other temperature dependence studies, the rate constants reported by Albu et al.² (at T = 250–299 K) suggest a significant negative activation energy, leading to suspicion of an interference from adduct reaction with impurity O₂. Absolute determinations lower than those recommended were obtained by Martin et al.,¹² Wallington et al.,¹⁷ and Nielsen et al.¹³ The reasons for these differences are not readily apparent. Confirmation that H-abstraction is the dominant pathway under the experimental conditions specified above comes from the studies of Stickel et al.¹⁴ and Turnipseed et al.¹⁵ Stickel et al. used tunable diode laser spectroscopy to measure an HDO product yield of 0.84 ± 0.15 for the OD + CH₃SCH₃ reaction in 10–30 Torr N₂, while Turnipseed et al. used laser induced fluorescence observations of CH₃S production from OH + CH₃SCH₃ to show that the branching ratio for the CH₃S elimination channel is <0.04 and the direct H-abstraction yield is 0.84 ± 0.26. Further support for the dominance of the H-abstraction pathway

comes from the work of Zhao et al.,²³ who obtained an upper limit yield of 0.07 for the methyl elimination channel in the OD + CH₃SCH₃ reaction. Barnes et al.,^{4,5} Turnipseed et al., and Urbanski et al.¹⁶ report that the abstraction product CH₃SCH₂ is converted predominantly to CH₃S under atmospheric conditions. Barnes et al.⁴ measure a 0.7% yield of OCS under low NO_x conditions, which they attribute to further oxidation of CH₃S. A theoretical study by Jorgensen and Kjaergaard suggests that complexation of CH₃SCH₃ with a single water molecule can speed up the reaction by lowering the energy of the transition state relative to the energy of the reactants.⁹

I20. OH + CH₃SCH₃ → (CH₃)₂SOH → products. The OH + CH₃SCH₃ reaction is complex, proceeding by both direct H-abstraction and reversible addition pathways. A recommendation for the direct reaction is given separately in Table 1 (see above). The product of the reversible addition pathway reacts with O₂ creating an irreversible path as well. Mechanistically, this pathway is described by combining the rate constants *k_f* for the addition step, *k_r* for the reverse dissociation step, and *k_{O2}* for the adduct reaction with O₂. The equilibrium constant for the reversible addition process is *K_c* = *k_f*/*k_r*. Recommendations for *K_c*, *k_f*, and *k_{O2}* are found in Tables 3, 2, and 1, respectively. Subtracting the temperature-dependent H-abstraction rate constant from the overall irreversible rate constant (which depends on T, P, and P_{O2}) yields the rate constant for irreversible addition (*k_{ia}*), which can be expressed as

$$k_{ia} = K_c k_{O2} [O_2] / (1 + (K_c k_{O2} [O_2] / k_f)).$$

Much of the kinetic data available for evaluating this reaction were obtained for OH + CD₃SCD₃. Although the methyl hydrogens are not directly involved in the reaction, the rate constants for OH addition reactions with CH₃SCH₃ and CD₃SCD₃ differ somewhat⁶ as they are in the low pressure limit where the value depends on the density of states, which are different for the two isotopomers. The recommended expression (units are cm³ molecule⁻¹ s⁻¹),

$$k_{ia}(T, [O_2], [M]) = 8.2 \times 10^{-39} [O_2] \exp(+5376/T) / (1 + 1.05 \times 10^{-5} ([O_2] / [M]) \exp(+3644/T)),$$

is based on the recommendations for *K_c*, *k_f*, and *k_{O2}* given elsewhere in this evaluation. It reproduces the data of Hynes et al.,² Williams et al.,⁴⁻⁶ and Albu et al.¹ quite well for both isotopomers and for all mole fractions of O₂ in N₂/O₂ mixtures; however, it should be used with caution at temperatures below 240 K (where no data are available) or above 310 K (where *k_{ia}* is very small). The 298 K relative rate study of Wang et al.³ suggests rate constants in air and pure O₂ at atmospheric pressure that are about a factor of two faster than those predicted by the above expression. Since the kinetic data of Hynes et al. and Williams et al. were obtained by monitoring OH loss, the overall rate constant for removal of CH₃SCH₃ would be underestimated if the adduct + O₂ reaction generated OH + dimethylsulfone (CH₃(O)S(O)CH₃) with a significant yield; the available data cannot rule out a small but significant branching ratio for this channel.

I21. (CH₃)₂SOH + O₂. All available kinetic data for this reaction were obtained by measuring k_{obs} for the OH + CH₃SCH₃ reaction as a function of O₂ partial pressure ($k_{\text{obs}} \equiv$ the sum of the rate constants for H-abstraction and irreversible addition). Much of the available data were obtained for OH + CD₃SCD₃. Since the methyl hydrogens are not directly involved in the reaction, the rate constant is expected to be virtually the same for CH₃SCH₃ as for CD₃SCD₃; hence, data for both reactants are used in the evaluation. The recommendation is based on the data of Hynes et al.,³ Barone et al.,¹ and Williams et al.^{8,9} The Hynes et al. study supersedes an earlier report of a considerably faster rate constant.⁴ Over the range of experimental conditions where data are available (222–267 K and 30–200 Torr), the rate constant appears to be independent of temperature and pressure. By monitoring the regeneration of OH in the presence of NO, Hynes et al.² and Turnipseed et al.⁷ have determined the yield for the HO₂ + CH₃S(O)CH₃ (DMSO) channel to be ~0.5. A theoretical study by Ramirez-Anguila et al.⁵ suggests possible pathways for generating CH₃SOH + CH₃OO/CH₂OOH. A second theoretical study by the same authors supports the experimental finding that the rate constant has little temperature or pressure dependence.⁶

I22. OH + CH₃SCH₂Cl. The recommendation is based on the low-pressure discharge flow resonance fluorescence study of Shallcross et al.¹ The uncertainty reflects the fact that only one study performed under a limited range of experimental conditions has been reported. Shallcross et al. suggest that the likely reaction pathway is H-abstraction under the low pressure conditions of their experiments. However, further experimental and/or theoretical research is needed before an addition-elimination pathway involving C–S bond cleavage can be ruled out. If H-abstraction dominates at low pressure, then under atmospheric conditions the rate constant could be significantly faster than reported by Shallcross et al. due to the occurrence of an irreversible addition channel at higher pressure and in the presence of O₂.

123. OH + CH₃SSCH₃. This recommendation is based on the temperature-dependent studies of Wine et al.⁷ and Abbott et al.¹ and the room temperature relative rate study of Cox and Sheppard.⁵ Domine and Ravishankara⁶ have observed both CH₃S (via laser-induced fluorescence) and CH₃SOH (via photo-ionization mass spectrometry) as products of this reaction. At 298 K, the yield of CH₃S alone was quantified at approximately 30%. An FTIR product study of the photooxidation of dimethyl disulfide by Barnes et al.² presents evidence that oxidation of the CH₃SOH product is the principal source of the methane sulfonic acid observed. Butkovskaya and Setser³ have observed that HDO and D₂O are produced from OD + CH₃SSCH₃ in the same proportion and with the same vibrational state distributions as the products observed by the same investigators in a similar study of the OD + CH₃SD reaction,⁴ leading these authors to suggest that the major product channel for OD + CH₃SSCH₃ is CH₃SD + CH₃SO.

124. OH + CH₃S(O)CH₃. The recommended 298 K rate constant is the average of the direct studies of Hynes and Wine,⁴ Urbanski et al.,⁸ and Kukui et al.,⁶ which employed three different experimental approaches and are in excellent agreement. Competitive kinetics studies by Barnes et al.² and Falbe-Hanson et al.³ report rate constants in 1 atm. of air about a factor of 1.5 slower than those obtained in the direct studies. The recommended value for E/R is based on the only study of the temperature dependence,⁴ where a significant negative activation energy was observed. The large uncertainty in E/R reflects the availability of very limited data (none below room temperature). The experimental studies of Urbanski et al., Kukui et al., and Arsene et al.,¹ as well as the theoretical study of Wang and Zhang,⁹ provide strong evidence that the dominant reaction channel is production of CH₃ + CH₃S(O)OH (MSIA, methanesulfinic acid). Arsene et al. attribute the failure to observe MSIA production in the chamber study of Sorensen et al.⁷ to loss via secondary gas phase and condensed phase oxidation before sampling. A theoretical study by Jorgensen and Kjaergaard suggests that the H-abstraction may be more important under atmospheric conditions than previously thought because (i) complexation of CH₃S(O)CH₃ with a single water molecule can speed up the H-abstraction reaction by lowering the energy of the transition state relative to the energy of the reactants and (ii) under atmospheric conditions a significant fraction of CH₃S(O)CH₃ is complexed with H₂O.⁵ However, as mentioned above, experimental information suggests that methyl elimination, not H-abstraction, is the dominant reaction pathway.

I25. OH + CH₃S(O)OH. The recommendation is based on a turbulent flow reactor – chemical ionization mass spectrometry study by Kukui et al.,² which was carried out with OH in excess over CH₃S(O)OH at total pressures of 200–400 Torr N₂. The large uncertainty factor results from the facts that (1) only a single room temperature study is reported in the literature and (2) CH₃S(O)OH is a difficult species to study in the gas phase because of its low vapor pressure. Kukui et al. found that SO₂ was produced as a reaction product with near unit yield, suggesting that the dominant reaction channel (at least in the absence of O₂) is production of CH₃ + SO₂ + H₂O. Theoretical studies by Gonzalez-Garcia et al.¹ and Tian et al.³ provide strong evidence that the CH₃S(O)OH–OH adduct is too short-lived to react with O₂ under atmospheric conditions. I26. OH + CH₃SO₃H. No gas-phase experimental data are available for this reaction, but a detailed theoretical study has been reported by Jorgensen et al.¹ Equilibrium and transition state structures were optimized using B3LYP density functional theory with the aug-cc-pV(T+d)Z basis set. Energies of stable species and transition states were refined using CCSD(T)-F12A theory with the VDZ-F12 basis set. Two different mechanisms were identified for producing CH₃SO₃ + H₂O, hydrogen atom transfer and proton coupled electron transfer. The 298 K rate constant was calculated using conventional transition state theory and found to be $8.3 \times 10^{-15} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$. Given that a 5 kJ mol⁻¹ error in a transition state energy can cause a factor of ten error in a calculated rate constant, the uncertainty in the theoretical rate constant is estimated to be around one order of magnitude. The role of water complexation with both reactants was examined theoretically and found to have no effect on the predicted rate constant under tropospheric conditions. (New Entry) [Back to Table](#)

I27. OH + CH₃SC₂H₅ → H-abstraction products. The recommendation is based on the 299 K study of Hynes et al.² and the temperature dependent (242–296 K) study of Williams et al.⁴ Oksdath-Mansilla et al.³ obtained a 298 K rate constant from a relative rate study that is 40% faster than the recommended value. A theoretical study by Cao et al.¹ suggests that abstraction of the secondary hydrogen is dominant (92% at 200 K and 85% at 300 K), with abstraction of the methyl hydrogen accounting for 7% of overall reactivity at 200 K and 12% at 300 K. (New Entry) [Back to Table](#)

Phys. Lett.* **2009**, 477, 22-27, doi:10.1016/j.cplett.2009.06.035.
- (4) Williams, M. B.; Campuzano-Jost, P.; Pounds, A. J.; Hynes, A. J. Experimental and theoretical studies of the reaction of the OH radical with alkyl sulfides: 2. Kinetics and mechanism of the OH initiated oxidation of methylethyl and diethyl sulfides; observations of a two channel oxidation mechanism. *Phys. Chem. Chem. Phys.* **2007**, 9, 4370-4382, doi:10.1039/b703957n.

I28. $\text{OH} + \text{CH}_3\text{SC}_2\text{H}_5 \xrightleftharpoons{\text{M}} \text{CH}_3\text{S}(\text{OH})\text{C}_2\text{H}_5 \xrightarrow{\text{O}_2} \text{products}$. The OH + $\text{CH}_3\text{SC}_2\text{H}_5$ reaction is complex, proceeding by both direct H-abstraction and reversible addition pathways. A recommendation for the H-abstraction reaction is given separately in Table 1 (see above). The product of the reversible addition pathway reacts with O_2 creating an irreversible addition path as well. Mechanistically, this pathway is described by combining the rate constants k_f for the addition step, k_r for the reverse dissociation step, and k_{O_2} for the adduct reaction with O_2 . The equilibrium constant for the reversible addition process is $K_c = k_f/k_r$. Subtracting the H-abstraction rate constant (which depends only on T) from the overall observed rate constant (which depends on T, P, and P_{O_2}) yields the rate constant for irreversible addition (k_{ia}), which can be expressed as

$$k_{\text{ia}} = K_c k_{\text{O}_2} [\text{O}_2] / (1 + (K_c k_{\text{O}_2} [\text{O}_2] / k_f)).$$

The expression given below (units are $\text{cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$) is obtained by substituting values for K_c , k_f , and k_{O_2} that are derived from the results of Williams et al.⁵ into the expression given above. Because data are available only over a limited range of experimental conditions, the expression below should be used only for air bath gas at $P = 680 \pm 80 \text{ Torr}$ and $T > 240 \text{ K}$.

$$k_{\text{ia}}(T, 680 \pm 80 \text{ Torr air}) = 1.17 \times 10^{-38} \exp(+5290/T) / (7.25 \times 10^{-22} T + 3.59 \times 10^{-26} \exp(+4170/T)).$$

The expression reproduces the laser flash photolysis data of Williams et al.,⁵ and the relative rate data of Oksdath-Mansilla et al.^{1,2} quite well. The relative rate study of Wang et al.⁴ suggests values for $k_{\text{abstraction}} + k_{\text{ir}}$ in 760 Torr air at $T = (297-346 \text{ K})$ that are faster than suggested by the above expression and are inconsistent with the results of the other available studies. Oksdath-Mansilla et al. report the following product yields in NO_x -free air at $P = 760 \text{ Torr}$ and $T = 298 \text{ K}$ (where irreversible addition is a minor but significant reaction pathway): SO_2 , $51 \pm 2\%$; CH_3CHO , $57 \pm 3\%$; HCHO , $46 \pm 4\%$.³

I29. $\text{CH}_3\text{S}(\text{OH})\text{C}_2\text{H}_5 + \text{O}_2$. The recommendation is based on the results of Williams et al.,¹ who extracted rate constants from measurements of k_{obs} for the OH + $\text{CH}_3\text{SC}_2\text{H}_5$ reaction as a function of O_2 partial pressure ($k_{\text{obs}} \equiv$ the sum of the rate constants for H-abstraction and irreversible addition). The derived rate constants were found to be independent of temperature (242–296 K) and pressure (200–600 Torr $\text{N}_2 + \text{O}_2$).

- I30. OH + S.** This recommendation is based on the study by Jourdain et al.¹ Their measured value for $k(298\text{ K})$ compares favorably with the recommended value of $k(\text{O} + \text{OH})$ when one considers the slightly greater exothermicity of the present reaction.

- I31. OH + SO.** The value recommended for $k(298\text{ K})$ is an average of the determinations by Fair and Thrush,² Jourdain et al.,³ and Blitz et al.¹ The result reported by Fair and Thrush was corrected using the present recommendation for the $\text{O} + \text{OH}$ reaction. The recommended value for E/R is taken from the temperature dependent data of Blitz et al. over the range 295–453 K. Higher temperature data of Blitz et al. are not used because significant curvature in the Arrhenius plot is observed at $T > 500\text{ K}$. The recommended value for g is conservative because only one temperature dependence study has been reported.

Technol.* **2009**, *43*, 1067-1070, doi:10.1021/es802439f.
- I33. HO₂ + H₂S, HO₂ + CH₃SH, HO₂ + CH₃SCH₃.** These upper limits are taken from the discharge flow laser magnetic resonance study of Mellouki and Ravishankara.³ The H₂S value disagrees with the rate constant reported by Bulatov et al.² by approximately three orders of magnitude. The reason for this difference is not readily apparent. However, the recommended upper limit is consistent with the values for CH₃SH and CH₃SCH₃, which respectively agree with upper limits from the work of Barnes et al.¹ and Niki (reported as a private communication in the Mellouki and Ravishankara paper).

- I34. HO₂ + SO₂.** This upper limit is based on the atmospheric pressure study of Graham et al.² A low pressure laser magnetic resonance study by Burrows et al.¹ places a somewhat higher upper limit on $k(298\text{ K})$ of $4 \times 10^{-17}\text{ cm}^3\text{ molecule}^{-1}\text{ s}^{-1}$ (determined relative to $\text{OH} + \text{H}_2\text{O}_2$). Their limit is based on the assumption that the products are OH and SO₃. The weight of evidence from both studies suggests an error in the earlier determination by Payne et al.³

- I35. NO₂ + SO₂.** This recommendation is based on the study of Penzhorn and Canosa² using second derivative UV spectroscopy. While these authors actually report a measured value for *k*(298 K), their observations of strong heterogeneous and water vapor catalyzed effects prompt us to accept their measurement as an upper limit. This value is approximately two orders of magnitude lower than that for a dark reaction observed by Jaffe and Klein,¹ much of which may have been due to heterogeneous processes. Penzhorn and Canosa suggest that the products of this reaction are NO + SO₃.

- I39. NO₃ + CH₃SH.** The recommended values are derived from a composite fit to the data of Wallington et al.,⁵ Rahman et al.,⁴ and Dlugokencky and Howard.¹ The room temperature rate constant derived in the relative rate experiments of MacLeod et al.³ is in good agreement with the recommended value. The suite of investigations shows the rate constant to be pressure independent over the range 1–700 Torr. Dlugokencky and Howard place an upper limit of 5% on the production of NO₂ via this reaction at low pressure. Based on the product distribution observed in their investigation, Jensen et al.² propose a reaction mechanism initiated

by abstraction of the hydrogen atom from the SH group, possibly after formation of an initial adduct as suggested by Wallington et al. and Dlugokencky and Howard.

N., Jr. Absolute rate constants for the gas-phase reactions of the NO₃ radical with CH₃SH, CH₃SCH₃, CH₃SSCH₃, H₂S, SO₂, and CH₃OCH₃ over the temperature range 280-350 K. *J. Phys. Chem.* **1986**, 90, 5393-5396, doi:10.1021/j100412a099.

I40. NO₃ + CH₃SCH₃. The recommended value for k(298 K) is obtained by averaging the rate constants reported by Tyndall et al.,¹¹ Dlugokencky and Howard,⁴ and Daykin and Wine.³ The recommended value of E/R is that reported by Dlugokencky and Howard. Tyndall et al. and Nakano et al.⁹ report data over rather narrow temperature ranges that are consistent with the Dlugokencky and Howard result. The relative rate study of Atkinson et al.¹ yields a rate constant at room temperature that is about a factor two lower than the recommended value. Wallington et al.^{12,13} also report rate constants that are somewhat lower than the recommended values; their results are suspect because their reaction mixtures contained F₂ in ten-fold excess over CH₃SCH₃, and it is now well-established that F₂ and CH₃SCH₃ react with each other rapidly.^{7,8,10} The results of Nakano et al. are suspect because of the likely presence of background NO₃ associated with the use of N₂O₅ + hv as the NO₃ source. The experimental data from all investigations demonstrate the pressure independence of the rate constant over the range 1–740 Torr. Jensen et al.⁵ propose a mechanism that involves hydrogen abstraction as the first step to explain their observed product distribution. In a later study, Jensen et al.⁶ measured a kinetic isotope effect for the rate constant for CH₃SCH₃ vs. that for CD₃SCD₃ of k_H/k_D = (3.8 ± 0.6), in agreement with the kinetic isotope effect reported by Daykin and Wine; this provides further confirmation of the H-abstraction mechanism. Butkovskaya and Le Bras² utilized chemical titration of the primary radical produced from NO₃ + CH₃SCH₃ in a discharge flow mass spectrometry system to show that the reaction produces predominantly CH₃SCH₂ + HNO₃. An upper limit of 2% was placed on the reaction channel yielding CH₃ + CH₃SONO₂.

- I41. NO₃ + CH₃SSCH₃.** The recommendation is based on the temperature dependent studies of Wallington et al.⁵ and Dlugokencky and Howard.² All data points in each temperature dependent study were scaled by a factor equal to the ratio $k(298\text{ K})_{\text{Arr}}/k(298\text{ K})_{\text{ave}}$ where $k(298\text{ K})_{\text{Arr}}$ is the 298 K rate constant obtained from Arrhenius expression describing the individual T-dependent data set and $k(298\text{ K})_{\text{ave}}$ is the average of the two $k(298\text{ K})_{\text{Arr}}$ values. The best fit of the scaled data to $\ln k = \ln A - E/RT$ is recommended. The investigation by Atkinson et al.¹ indicates that the relative rate technique cannot be considered as yielding reliable rate data for this reaction due to chemical complexities. Thus, the much lower room temperature results from the study of MacLeod et al.⁴ can be considered to be erroneous. Based on their observations of intermediate and end products, Jensen et al.³ proposed a reaction mechanism in which the initial addition of NO₃ to one of the sulfur atoms results in formation of CH₃S + CH₃SO + NO₂.

- (5) Wallington, T. J.; Atkinson, R.; Winer, A. M.; Pitts, J. N., Jr. Absolute rate constants for the gas-phase reactions of the NO₃ radical with CH₃SH, CH₃SCH₃, CH₃SSCH₃, H₂S, SO₂, and CH₃OCH₃ over the temperature range 280-350 K. *J. Phys. Chem.* **1986**, 90, 5393-5396, doi:10.1021/j100412a099.
- I42. NO₃ + CH₃S(O)CH₃.** The recommended value for $k(298\text{ K})$ is the geometric mean of the rate constants reported by Barnes et al.¹ and Falbe-Hansen et al.² from similar competitive kinetics studies; the reported rate constants and associated 2σ uncertainties in units of 10⁻¹³ cm³ molecule⁻¹ s⁻¹ are 1.7 ± 0.6 (Barnes et al.) and 5.0 ± 3.8 (Falbe-Hansen et al.). In both studies, the only observed sulfur-containing end-product was dimethylsulfoxide (CH₃(O)S(O)CH₃). Barnes et al. suggest that reaction proceeds via formation of an adduct that rapidly decomposes to NO₂ + CH₃(O)S(O)CH₃.

- I43. NO₃ + CH₃SC₂H₅.** The recommendation is the geometric mean of rate constants for NO₃ reactions with CH₃SCH₃ (k_1) and C₂H₅SC₂H₅ (k_2) reported by Daykin and Wine,¹ while the recommended uncertainty is large enough to include both k_1 and k_2 within its limits. Observation of the trend in rate constants for reactions of NO₃ radicals with CH₃SCH₃, CD₃SCD₃, and C₂H₅SC₂H₅ suggests that H-transfer is the dominant pathway for these reactions.¹ Products of the NO₃ + CH₃SC₂H₅ reaction measured in an environmental chamber by Jensen et al.² using a combination of FTIR and ion chromatographic detection also supports H-transfer as the dominant pathway and suggests that yields of the H-transfer products CH₂SCH₂CH₃ and CH₃SCHCH₃ are approximately equal.

- I46. CH₃O₂ + SO₂.** This recommendation accepts the results from the study of Sander and Watson.⁴ These authors conducted experiments using much lower CH₃O₂ concentrations than employed in the earlier investigations of Sanhueza et al.⁵ and Kan et al.,³ both of which resulted in k(298 K) values approximately 100 times greater. A later report by Kan et al.² postulates that these differences are due to the reactive removal of the CH₃O₂SO₂ adduct at high CH₃O₂ concentrations prior to its reversible decomposition into CH₃O₂ and SO₂. They suggest that such behavior of CH₃O₂SO₂ or its equilibrated adduct with O₂ (CH₃O₂SO₂O₂) would be expected in the studies yielding high k values, while decomposition of CH₃O₂SO₂ into reactants would dominate in the Sander and Watson experiments. It does not appear likely that such secondary reactions involving CH₃O₂, NO, or other radical species would be rapid enough, if they occur under normal atmospheric conditions to compete with the adduct decomposition. This interpretation, however, does not explain the high rate constant derived by Cocks et al.¹ under conditions of low [CH₃O₂].

- I47. CH₂OO + SO₂.** The recommendation is the average of rate constants reported in the experimental studies of Chhantyal-Pun et al.,¹ Liu et al.,⁵ Sheps,⁶ Stone et al.,⁷ and Welz et al.,⁹ with equal weighting given to each of the five studies (independent of the number of rate constants reported in each study). In all five studies

CH₂OO was produced by laser flash photolysis of CH₂I₂/O₂, while kinetic information was obtained by (i) monitoring reactant CH₂OO using photoionization mass spectrometry,^{7,9} cavity ring down spectroscopy,¹ or broadband cavity-enhanced spectrometry,⁶ (ii) product H₂CO using laser induced fluorescence (LIF),⁷ or (iii) OH, deduced to be a tracer for CH₂OO kinetics, using LIF.⁵ The available data suggest that the rate constant is independent of pressure over the range 1.5–450 Torr N₂ + O₂, and the average rate constants reported in the five studies all fall within the range $(3.4 - 4.1) \times 10^{-11} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$. A theoretical kinetic analysis predicts a rate constant in qualitative agreement with the experimental value.⁴ An early mechanistic study by Hatakeyama et al.² suggested that, under the laboratory conditions employed, an initially formed CH₂OO–SO₂ adduct either decomposes to HCOOH + SO₂ or reacts with a second SO₂, leading to production of H₂CO + SO₃. A theoretical study by Jiang et al.³ suggests that reaction proceeds via formation of a cyclic adduct that is bound by 117 kJ mol⁻¹ and dissociates over barriers that are lower in energy than reactants to produce H₂CO + SO₃ and HCOOH + SO₂; the barrier to formation of the more stable products (HCOOH + SO₂) is predicted to be larger than the barrier to formation of the less stable products (H₂CO + SO₃). Vereecken et al.⁸ have theoretically considered the role of singlet biradicals in the reaction mechanism and concluded that it is substantial; their master equation analysis suggests that, under atmospheric conditions, reaction is in the low pressure regime and the energized cyclic adduct fragments to 68% H₂CO + SO₃, 15% HC(=O)–OS(=O)OH (formyl sulfinic ester), and 17% SO + >C(O•)O• (singlet bisoxy diradical). - I48. anti-CH₃CHOO + SO₂.** Experimental measurements of *k*(298 K) have been reported by Taatjes et al.² and Sheps et al.² In both studies CH₃CHOO was produced by UV laser flash photolysis of CH₃CHI₂/O₂. Taatjes et al. monitored CH₃CHOO using time-resolved photoionization mass spectrometry; the *anti* and *syn* conformers could be differentiated in the detection scheme because they have different ionization potentials. Sheps et al. used time-resolved broadband (300–450 nm) cavity-enhanced spectrometry to monitor both conformers simultaneously; they determined spectra of the individual conformers based on their very different reactivities toward H₂O and SO₂. The rate constant reported by Sheps et al. is more than a factor of three faster than the one reported by Taatjes et al. The Sheps et al. rate constant is recommended because their approach appears to provide better sensitivity and selectivity for detection of the *anti* conformer in the presence of the less reactive *syn* conformer. The recommended uncertainty is somewhat larger than reported by Sheps et al. pending independent verification of their result. Theoretical analysis by Kuwata et al.¹ suggests that the *anti* conformer is 14 kJ mol⁻¹ higher in energy than the *syn* conformer. Theoretical analysis by Vereecken et al.³ suggests that (unlike CH₂OO–SO₂) nearly all energized CH₃CHCOO–SO₂ adduct is stabilized under atmospheric conditions. (New Entry) [Back to Table](#)

I49. $\text{syn-CH}_3\text{CHOO} + \text{SO}_2$. Experimental measurements of $k(298\text{ K})$ have been reported by Taatjes et al.² and Sheps et al.² In both studies CH_3CHOO was produced by UV laser flash photolysis of $\text{CH}_3\text{CHI}_2/\text{O}_2$. Taatjes et al. monitored CH_3CHOO using time-resolved photoionization mass spectrometry; the *anti* and *syn* conformers could be differentiated in the detection scheme because they have different ionization potentials. Sheps et al. used time-resolved broadband (300-450 nm) cavity-enhanced spectrometry to monitor both conformers simultaneously; they determined spectra of the individual conformers based on their very different reactivities toward H_2O and SO_2 . The rate constants reported by the two groups are in good agreement, and the average of the two reported rate constants is recommended. Theoretical analysis by Kuwata et al.¹ suggests that the *syn* conformer is 14 kJ mol^{-1} lower in energy than the *anti* conformer. Theoretical analysis by Vereecken et al.³ suggests that (unlike $\text{CH}_2\text{OO-SO}_2$) nearly all energized $\text{CH}_3\text{CHCOO-SO}_2$ adduct is stabilized under atmospheric conditions.

I50. $\text{F} + \text{CH}_3\text{SCH}_3$. This recommendation is based on the discharge flow mass spectrometric study by Butkovskaya et al.¹ The uncertainty placed on this recommendation has been increased over that estimated by the authors to reflect the lack of confirming investigations. Titration of the primary organic radical products indicated that the reaction proceeds via two channels to produce $\text{HF} + \text{CH}_3\text{SCH}_2$ and $\text{CH}_3 + \text{CH}_3\text{SF}$ with a branching ratio of approximately 0.8/0.2 respectively.
(Table: 97-4, Note: 97-4, Evaluated: 97-4) [Back to Table](#)

I51. $\text{Cl} + \text{H}_2\text{S}$. This recommendation is based on the study by Nicovich et al.,⁹ who conducted an elaborate study with attention to sources of possible systematic error. The rate constant at 298 K is in good agreement with that determined by Nesbitt and Leone,⁸ who refined the data of Braithwaite and Leone,¹ but is significantly greater than the values reported by Clyne and Ono,⁴ Clyne et al.,³ Nava et al.,⁷ and Chen et al.² The small, but clearly observed, negative activation energy determined by Nicovich et al. contrasts with the lack of a temperature dependence observed by Nava et al. In fact, at the lowest temperature of overlap, the results from these two studies differ by 50%. Nevertheless, the Nicovich et al. study yields consistent results for both H_2S and CH_3SH as well as for D_2S and CD_3SD . In addition, Hossenlopp et al.⁵ report a room temperature rate constant for $\text{Cl} + \text{D}_2\text{S}$ that is in excellent agreement with the value reported by Nicovich et al. While the reason for these differences remains to be determined, the full range of reported values is encompassed within the 2σ error limits recommended. Lu et al.⁶ also measured a temperature-independent rate constant but report a value at 298 K that is about 40% greater than that of Nicovich et al. However, the presence of 4000 Torr of CF_3Cl bath gas in the Lu et al. study may suggest a slight pressure dependence of the reaction, although Nicovich et al. observed no pressure dependence for pressures ranging up to 600 Torr N_2 . A theoretical study by Wilson and Hirst¹⁰ suggests the dominance of an addition-elimination pathway with a small but significant fraction of reactive events occurring via a direct hydrogen abstraction mechanism.

- I52. $\text{Cl} + \text{SO}_2\text{F}_2 \rightarrow \text{products}$.** The recommended upper limit is a factor of 3 higher than that reported in the relative rate experiments of Sulbaek-Andersen et al.² to account for a large uncertainty in the rate constant for the reference reaction they employed ($\text{Cl} + \text{CF}_3\text{CH}_3$). A less sensitive upper limit is reported by Papadimitriou et al.¹.
(Table: 10-6, Note: 10-6, Evaluated: 10-6) [Back to Table](#)
- (1) Papadimitriou, V. C.; Portmann, R. W.; Fahey, D. W.; Muhle, J.; Weiss, R. F.; Burkholder, J. B. Experimental and theoretical study of the atmospheric chemistry and global warming potential of SO_2F_2 . *J. Phys. Chem. A* **2008**, 112, 12657-12666, doi:10.1021/jp806368u.

Technol.* **2009**, 43, 1067-1070, doi:10.1021/es802439f.
- I53. $\text{Cl} + \text{OCS}$.** This upper limit is based on the minimum detectable decrease in atomic chlorine measured by Eibling and Kaufman.² Based on the observation of product SCl , these authors set a lower limit on $k(298 \text{ K})$ of $10^{-18} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ for the $\text{SCl} + \text{CO}$ reaction channel. Considerably higher upper limits on $k(298 \text{ K})$ were determined in the studies of Clyne et al.¹ and Nava et al.³
(Table: 83-62, Note: 87-41, Evaluated: 83-62) [Back to Table](#)

- I54. $\text{CS}_2\text{Cl} + \text{O}_2$.** This recommendation is based on the study of Nicovich et al.² who employed a laser flash photolysis resonance fluorescence technique to observe the effect of added O_2 on the kinetics of the $\text{Cl} + \text{CS}_2 \leftrightarrow \text{CS}_2\text{Cl}$ equilibration reactions. Martin et al.¹ report competitive kinetics results which they interpret as suggesting a fast $\text{CS}_2\text{Cl} + \text{O}_2$ reaction, but Wallington et al.³ have suggested that secondary production of OH in the photochemical system employed by Martin et al. is responsible for the observed dependence of the CS_2 loss rate on $[\text{O}_2]$.
(Table: 06-2, Note: 06-2, Evaluated: 06-2) [Back to Table](#)
- (1) Martin, D.; Barnes, I.; Becker, K. H. Rate constant and products of the reaction $\text{Cl} + \text{CS}_2$ in air. *Chem. Phys. Lett.* **1987**, 140, 195-199.

- (2) Nicovich, J. M.; Shackelford, C. J.; Wine, P. H. Kinetics and thermochemistry of reversible adduct formation in the reaction of $\text{Cl}(^2\text{P}_1)$ with CS_2 . *J. Phys. Chem.* **1990**, 94, 2896-2903.

I55. $\text{Cl} + \text{CH}_3\text{SH}$. This recommendation is based on the results of Nicovich et al.,⁴ who used laser flash photolysis with resonance fluorescence detection to study the reactions of Cl with H_2S , D_2S , CH_3SH , and CD_3SD . The room temperature determination by Nesbitt and Leone² is in good agreement with the recommended value. The $k(298\text{ K})$ value from the study of Mellouki et al.¹ is nearly a factor of 2 lower. However, the low sensitivity of EPR detection of Cl atoms did not permit these latter authors to conduct a precise determination of k under pseudo first-order conditions, and a more complex analysis of experiments conducted under second-order conditions was required. Nesbitt and Leone³ report that $2 \pm 1\%$ of the reaction occurs via abstraction of an H atom from the CH_3 group. A theoretical study by Wang et al. supports abstraction of H from the SH group as the dominant reaction pathway at atmospheric temperatures, but predicts that abstraction of H from the CH_3 group becomes important at higher temperatures.⁵ A theoretical study by Wilson and Hirst⁶ predicts a Cl-S adduct bond strength (298 K) of 57 kJ mol^{-1} , but is unable to deduce the relative importance of addition-elimination vs. direct hydrogen abstraction pathways. (Table: 06-2, Note: 15-10, Evaluated: 06-2) [Back to Table](#)

I56. $\text{Cl} + \text{CH}_3\text{SCH}_3$. Stickel et al.⁹ have used laser flash photolysis resonance fluorescence to measure the rate constant between 240 and 421 K, over the pressure range 3–700 Torr. The rate constant is near the gas-kinetic collision limit but increases with increasing pressure from a low pressure limit of 1.8×10^{-10} to a value of $3.3 \times 10^{-10}\text{ cm}^3\text{ molecule}^{-1}\text{ s}^{-1}$ at 700 Torr. The yield of HCl at 297 K, measured by diode laser spectroscopy, decreased from near unity at low pressure to a value of approximately 0.5 at 203 Torr, suggesting that stabilization of a $(\text{CH}_3)_2\text{SCL}$ adduct becomes competitive with hydrogen atom abstraction with increasing pressure. These investigators also observed a negative temperature dependence for the reaction at low pressure. Butkovskaya et al.² conducted a discharge flow mass spectrometry study at 298 K, in which they determined that the reaction proceeds to form $\text{HCl} + \text{CH}_3\text{SCH}_2$ almost exclusively at 1 Torr total pressure. The sum of all other possible channels was estimated at less than 3%. Zhao et al.¹³ used laser photolysis coupled with CH_3 detection by time-resolved tunable diode laser absorption spectroscopy to determine an upper limit yield of 0.02 for CH_3 elimination at 298 K and pressures in the range 10–30 Torr. Langer et al.⁶ coupled cw photolysis with gas chromatographic detection of products to show that the yield of CH_3Cl is $(1.34 \pm 0.07) \times 10^{-3}$. Theoretical studies by Wilson and Hirst,¹² Resende and De Almeida,⁸ and Thompson et al.¹⁰ support the experimentally observed dominance of the H -abstraction pathway at low pressure. Diaz-de-Mera et al.³ have employed a discharge flow – mass spectrometry technique to measure rate constants at pressures of 0.5–1.0 Torr He over the temperature range 259–364 K. The 298 K rate constant reported by Diaz-de-Mera et al. is nearly a factor of 3 slower than the low-temperature limit value reported by Stickel et al. Furthermore, Diaz-de-Mera et al. report a small positive activation energy whereas Stickel et al. report a small negative activation energy. The present recommendation for the H -abstraction pathway is based on an extrapolated low pressure limit rate constant obtained from the data of Stickel et al., with the uncertainty adjusted to encompass the result of Diaz-de-Mera et al. The data of Stickel et al. suggest that a high pressure limit is reached at $P \sim 150$ Torr. Urbanski and Wine¹¹ have observed the UV-visible absorption spectrum of $(\text{CH}_3)_2\text{SCL}$ in 155 Torr O_2 and used absorbance rise-time data to derive a rate constant that agrees well with those measured by Stickel et al. at pressures of 150–750 Torr N_2 . Enami et al.⁴ have observed the kinetics of adduct formation using cavity ring down spectroscopy, and derived rate constants over the temperature and pressure ranges 278–318 K and 20–300 Torr N_2 that also agree well with those

reported by Stickel et al. Room temperature competitive kinetics measurements by Nielsen et al.⁷ at 740 Torr, Kinnison et al.⁵ at 760 Torr, and Arsene et al.¹ at 750 Torr agree quite well with the results of Stickel et al., Urbanski and Wine, and Enami et al. Kinnison et al. and Arsene et al. report that the rate constant at atmospheric pressure is ~20% faster in synthetic air than in N₂ bath gas, suggesting that the (CH₃)₂SCl adduct reacts with O₂; however, the results of Urbanski and Wine, and Enami et al. argue against the occurrence of such a reaction. Stickel et al. report that the high-pressure rate constant in N₂ is independent of temperature whereas Arsene et al. report large negative activation energies in both N₂ and synthetic air bath gases. The large negative activation energies reported by Arsene et al. seem unlikely to result from a two-channel elementary reaction (H-abstraction and addition); hence, the recommended E/R is that reported by Stickel et al.

I57. (CH₃)₂SCl + O₂, NO, NO₂. The recommended values for k(298 K) are based on the study of Urbanski and Wine² which combined laser flash photolytic production of (CH₃)₂SCl with kinetic observations by time-resolved absorption spectroscopy. The recommended uncertainties for the NO and NO₂ reactions are larger than those reported by Urbanski and Wine pending independent confirmation of their results. As in the Urbanski and Wine study, Enami et al.¹ report no observable reaction between (CH₃)₂SCl and O₂.

(Table: 06-2, Note: 06-2, Evaluated: 06-2) [Back to Table](#)

- (1) Enami, S.; Nakano, Y.; Hashimoto, S.; Kawasaki, M.; Aloisio, S.; Francisco, J. S. Reactions of Cl atoms with dimethyl sulfide: A theoretical calculation and an experimental study with cavity ring-down spectroscopy. *J. Phys. Chem. A* **2004**, *108*, 7785-7789, doi:10.1021/jp049772y.

158. $\text{Cl} + \text{CH}_3\text{S}(\text{O})\text{CH}_3 \rightarrow \text{CH}_3\text{S}(\text{O})\text{CH}_2 + \text{HCl}$. The recommended value of $k(298\text{ K})$ for H-abstraction is based on the analysis of Nicovich et al.,⁴ who fit the combined room temperature data of Nicovich et al., Martinez et al.,³ and Riffault et al.,⁵ which spanned an effective N_2 pressure range of 0.3-505 Torr, to the sum of a pressure-dependent component and a pressure-independent component and attributed the pressure-independent component to H-abstraction. The temperature dependence studies of Martinez et al. (273–335 K) and Nicovich et al. (438–571 K) suggest the possibility of curvature in the Arrhenius plot. The recommended E/R ($= 0$) is appropriate for the 200–300 K temperature regime but not for higher temperatures. Vandresen and Resende⁷ report a theoretical rate constant of $1.2 \times 10^{-10} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$, i.e., a factor of seven faster than the value suggested by experimental results. A theoretical study by Mao et al. suggests that DMSO complexation with water affects the rate constant for the H-abstraction reaction.² It has been predicted theoretically by Asatryan and Bozzelli¹ and confirmed experimentally by Taatjes et al.⁶ that the peroxy radical formed via reaction of product $\cdot\text{CH}_2\text{S}(\text{O})\text{CH}_3$ with O_2 rapidly dissociates to produce the Criegee intermediate, CH_2OO .

159. $\text{CH}_3(\text{Cl})\text{S}(\text{O})\text{CH}_3 + \text{O}_2, \text{NO}, \text{NO}_2$. The recommendations are based on the study of Kleissas et al.¹ which combined laser flash photolytic production of $\text{CH}_3(\text{Cl})\text{S}(\text{O})\text{CH}_3$ with kinetic observations by time-resolved absorption spectroscopy. The recommended uncertainties for the NO and NO_2 reactions are larger than those reported by Kleissas et al. pending independent confirmation of their results.

160. $\text{Cl} + \text{CH}_3\text{SC}_2\text{H}_5$. The recommendation for $k(298\text{ K})$ is the average of rate constants reported in two relative rate studies that employed a total of five different reference compounds;^{1,2} all data were obtained at $T = 298\text{ K}$ and $P = 760\text{ Torr}$ air. Since both pressure independent H-abstraction pathways and a pressure dependent addition pathway are likely to be important, the recommended rate coefficient is only valid for $P \sim 1\text{ atm}$ $\text{N}_2 + \text{O}_2$. The following product yields are reported in 760 Torr of NO_x -free air: 43% for HCl, 55% for SO_2 , 58% for CH_3CHO , and 58% for H_2CO .³

I61. $\text{Cl}_2 + \text{CH}_3\text{SCH}_3$. Dyke et al.³ have employed a flow tube technique with reactant and product detection by photoelectron spectroscopy to obtain a rate constant of $(3.4 \pm 0.7) \times 10^{-14} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ at 294 K and 1.6–3.0 Torr helium bath gas (the reported uncertainty is 1σ , precision); this rate constant is consistent with an upper limit value of $8 \times 10^{-14} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ at 298 K in 1 Torr helium reported by Butkovskaya et al.¹ Dyke et al.² have obtained the photoelectron spectrum of a reaction intermediate that they assign as $(\text{CH}_3)_2\text{S}-\text{Cl}_2$ (each Cl bound to S). A theoretical analysis suggests that the observed intermediate is stable by 26.3 kcal mol⁻¹ relative to reactants and dissociates over a 29.0 kcal mol⁻¹ barrier to the end products HCl + $\text{CH}_3\text{SCH}_2\text{Cl}$, both of which were observed by photoelectron spectroscopy.² Because it is not clear how Dyke et al. differentiated gas phase reaction of Cl_2 with CH_3SCH_3 from reaction on the flow tube walls in their investigation,³ the recommendation treats their result plus two standard deviations as an upper limit for the gas phase rate constant.

I62. $\text{ClO} + \text{OCS}$; $\text{ClO} + \text{SO}_2$. These recommendations are based on the discharge flow mass spectrometric data of Eibling and Kaufman.¹ The upper limit on $k(298 \text{ K})$ for $\text{ClO} + \text{OCS}$ was set from the minimum detectable decrease in ClO. No products were observed. The upper limit on $k(298 \text{ K})$ for $\text{ClO} + \text{SO}_2$ is based on the authors' estimate of their SO_3 detection limit. The upper limit for this same reaction based on the minimum detectable decrease in ClO was not used due to the potential problem of ClO reformation from the $\text{Cl} + \text{O}_3$ source reaction.

- (1) Eibling, R. E.; Kaufman, M. Kinetics studies relevant to possible coupling between the stratospheric chlorine and sulfur cycles. *Atmos. Environ.* **1983**, *17*, 429-431.

I63. $\text{ClO} + \text{CH}_3\text{SCH}_3$. The 298 K recommendation is the average of the values reported in discharge flow mass spectrometry studies by Barnes et al.¹ and Diaz-de-Mera et al.² Barnes et al. prefer their more recent rate constant to one a factor of 4 higher than they determined using an earlier version of their apparatus. The recommendation for E/R is based on the temperature dependence observed by Diaz-de-Mera et al. over the range 259–335 K. The uncertainty factors reflect the fact that the two reported values for $k(298 \text{ K})$ differ by more than a factor of two and that the activation energy is defined by data from a single study over a moderately narrow temperature range.

I64. $\text{ClO} + \text{CH}_3\text{S(O)CH}_3$. The recommendation is based on the results of a low-pressure discharge flow mass spectrometry study by Riffault et al.¹ These investigators were also able to establish an even lower upper limit of $2 \times 10^{-15} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ for the channel that produces Cl atoms

- 166. Br + H₂S, Br + CH₃SH.** These recommendations are based on the study by Nicovich et al.¹ who measured both the forward and reverse reactions by time-resolved resonance fluorescence detection of Br atoms. The uncertainties placed on these recommendations have been increased over those estimated by the authors to reflect the absence of any confirming investigations.
(Table: 94-26, Note: 94-26, Evaluated: 94-26) [Back to Table](#)
- (1) Nicovich, J. M.; Kreutter, K. D.; van Dijk, C. A.; Wine, P. H. Temperature dependent kinetics studies of the reactions $\text{Br}(^2\text{P}_{3/2}) + \text{H}_2\text{S} \leftrightarrow \text{SH} + \text{HBr}$ and $\text{Br}(^2\text{P}_{3/2}) + \text{CH}_3\text{SH} \leftrightarrow \text{CH}_3\text{S} + \text{HBr}$. Heats of formation of SH and CH₃S radicals. *J. Phys. Chem.* **1992**, *96*, 2518-2528.
- 167. Br + CH₃SCH₃.** It is well-established based on studies by Wine et al.,⁶ Ingham et al.,² and Nakano et al.⁵ that, under atmospheric conditions, attack of Br on CH₃SCH₃ occurs predominantly by addition to the sulfur atom. Above 375 K, adduct decomposition is so rapid that the addition channel is effectively negligible. Jefferson et al.³ report high temperature experiments where the individual hydrogen transfer reactions $\text{Br} + \text{CH}_3\text{SCH}_3 \rightarrow \text{CH}_3\text{SCH}_2 + \text{HBr}$ (forward reaction) and $\text{CH}_3\text{SCH}_2 + \text{HBr} \rightarrow \text{Br} + \text{CH}_3\text{SCH}_3$ (reverse reaction) were isolated in a laser flash photolysis resonance fluorescence system, and their kinetics were separately studied over the temperature range 386–604 K. These investigators determined Arrhenius expressions for the forward and reverse reactions to be $9.0 \times 10^{-11} \exp(-2386/T)$ and $8.6 \times 10^{-13} \exp(+836/T) \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$, respectively. Analysis of the equilibrium data also permitted determination of the heat of formation of CH₃SCH₂ (see Appendix 1). Extrapolation of the Jefferson et al. Arrhenius expression to 298 K gives a rate constant for the non-adduct-forming part of the Br + CH₃SCH₃ reaction (presumably direct hydrogen abstraction) of $3.0 \times 10^{-14} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$. This estimated rate constant agrees quite well with the value of $(4.9 \pm 2.0) \times 10^{-14} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ obtained in a competitive kinetics study at atmospheric pressure in air by Ballesteros et al.,¹ and is consistent with an upper limit of $1 \times 10^{-13} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ reported in a similar study by Maurer et al.⁴ Direct comparison of the Jefferson et al. and Ballesteros et al. kinetic data is warranted only if essentially all adduct formation is reversible in the Ballesteros et al. experiment, which is possible based on the apparent absence of an adduct + O₂ pathway,^{4,5} but is not yet well-established. The recommendation for the pressure-independent bimolecular reaction is based on extrapolation of the Arrhenius expression of Jefferson et al. to the atmospheric temperature regime. The large uncertainty reflects the need for a rather long extrapolation.

- 168. Br + CH₃S(O)CH₃.** The recommendation is based on the results of a low-pressure discharge flow mass spectrometry study by Riffault et al.² These authors obtained an upper limit for the total rate constant of $1.5 \times 10^{-14} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$, and also report channel-specific rate constants in units of $10^{-15} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ of 11 ± 3 for the H-abstraction channel and 1.2 ± 0.3 for the methyl elimination channel. A competitive kinetics study in 740 Torr air by Ballesteros et al.¹ reports a less sensitive upper limit rate constant of $6 \times 10^{-14} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$.

- (1) Ballesteros, B., N. R. Jensen, and J. Hjorth FT-IR study of the kinetics and products of the reactions of dimethylsulphide, dimethylsulphoxide and dimethylsulphone with Br and BrO. *J. Atmos. Chem.* **2002**, 43, 135-150.
 - (2) Riffault, V.; Bedjanian, Y.; Le Bras, G. Kinetic and mechanistic study of the X and XO (X = Cl, Br) reactions with dimethyl sulfoxide. *Phys. Chem. Chem. Phys.* **2003**, 5, 2828-2835, doi:10.1039/b302675b.
- 169. BrO + CH₃SH.** The recommendation is based on the low-pressure discharge flow mass spectrometry study of Aranda et al.¹ A significant negative activation energy of $-6.9 \pm 2.0 \text{ kJ/mol}$ was observed at P = 1.0 Torr He over the temperature range 259–333 K. At T = 298 K, reported rate coefficients in units of $10^{-14} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ increase with increasing helium pressure from 2.7 ± 0.5 at P = 0.5 Torr to 4.9 ± 0.4 at P = 3.0 Torr. HOBr was observed as a reaction product suggesting that an important reaction pathway is addition of BrO to CH₃SH followed by dissociation to HOBr + CH₃S in competition with dissociation to reactants. Until kinetic data are reported at higher pressures, no recommendation of appropriate rate constants for atmospheric modeling is made.

- 170. BrO + CH₃SCH₃.** This recommendation is an average of results obtained in the discharge flow studies of Barnes et al.² and Bedjanian et al.,³ and the flash photolysis studies of Ingham et al.⁴ and Nakano et al.⁵ The flash photolysis studies were carried out at pressures of 60–200 Torr and give rate constants that are almost a factor of two greater than those obtained in the discharge flow studies at P ~1 Torr. The error limits in the present evaluation are adjusted to include all available data. A new study to investigate the pressure dependence of the rate constant is needed. Both Bedjanian et al. and Ingham et al. have shown that DMSO (CH₃S(O)CH₃) is produced with near unit yield. Ballesteros et al.¹ report that the rate constants for BrO + CH₃SCH₃ and BrO + CD₃SCD₃ are identical, a result that is consistent with reaction proceeding via formation of a short-lived adduct that rapidly decomposes to Br + DMSO.

- 171. BrO + CH₃SSCH₃.** The recommendation is based on a competitive kinetics study in 740 Torr air by Ballesteros et al.¹ The large uncertainty factor results from the fact that the reported rate constant is measured relative to an assumed value of $3.2 \times 10^{-13} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ for the BrO + CH₃SCH₃ rate constant, which has an uncertain pressure dependence (see above), and from the fact that there is only a single study upon which to base a recommendation.
(Table: 06-2, Note: 06-2, Evaluated: 06-2) [Back to Table](#)

- (1) Ballesteros, B., N. R. Jensen, and J. Hjorth FT-IR study of the kinetics and products of the reactions of dimethylsulphide, dimethylsulphoxide and dimethylsulphone with Br and BrO. *J. Atmos. Chem.* **2002**, 43, 135-150.
- I72. BrO + CH₃S(O)CH₃.** The recommendation is based on a competitive kinetics study in 740 Torr air by Ballesteros et al.¹ A low-pressure discharge flow mass spectrometry study by Riffault et al.,² gives an upper limit that is consistent with the recommendation. The large uncertainty factor results primarily from the fact that the reported rate constant is obtained from a series of competitive kinetics experiments that are referenced to an assumed value of $3.2 \times 10^{-13} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ for the BrO + CH₃SCH₃ rate constant, which has an uncertain pressure dependence (see above).
(Table: 06-2, Note: 06-2, Evaluated: 06-2) [Back to Table](#)
- (1) Ballesteros, B., N. R. Jensen, and J. Hjorth FT-IR study of the kinetics and products of the reactions of dimethylsulphide, dimethylsulphoxide and dimethylsulphone with Br and BrO. *J. Atmos. Chem.* **2002**, 43, 135-150.

- I74. IO + CH₃SH.** The value of k(298 K) comes from the study by Maguin et al.¹ using discharge flow mass spectrometry. The investigators establish a branching ratio near unity for the production of HOI. The uncertainty factor reflects the absence of confirming investigations.
(Table: 94-26, Note: 94-26, Evaluated: 94-26) [Back to Table](#)
- (1) Maguin, F.; Mellouki, A.; Laverdet, G.; Poulet, G.; Le Bras, G. Kinetics of the reactions of the IO radical with dimethyl sulfide, methanethiol, ethylene, and propylene. *Int. J. Chem. Kinet.* **1991**, 23, 237-245.
- I75. IO + CH₃SCH₃.** The recommendation is based on the temperature-dependent studies of Gravestock et al.⁵ and Dillon et al.⁴ and the 298 K studies of Maguin et al.,⁷ Barnes et al.,¹ and Knight et al.⁶ All data points in each temperature dependent study were scaled by a factor equal to the ratio $k(298 \text{ K})_{\text{Arr}}/k(298 \text{ K})_{\text{ave}}$ where $k(298 \text{ K})_{\text{Arr}}$ is the 298 K rate constant obtained from the best fit Arrhenius expression describing the individual T-dependent data set and $k(298 \text{ K})_{\text{ave}}$ is the average of all reported 298 K rate constants (using $k(298 \text{ K})_{\text{Arr}}$ from the T-dependent studies). The best fit of the scaled data to $\ln k = \ln A - E/RT$ is recommended. The studies of Maguin et al. and Barnes et al. supersede earlier, less direct measurements by the same groups,^{2,8} which reported much greater rate constants. Nakano et al.⁹ employed a laser flash photolysis cavity ring down spectroscopy technique to investigate the temperature and pressure dependence of the rate constant. These investigators report that the 298 K rate constant increases from 1 to $25 \times 10^{-14} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ as pressure increases from 5 to 100 Torr N₂, then levels off at higher pressure. Nakano et al. also investigated the temperature dependence of the rate constant at P = 100 Torr and observed a very strong negative temperature dependence, i.e., $E/R = -2230 \pm 460 \text{ K}$. The pressure dependence reported by Nakano et al. is in conflict with the results of Daykin and Wine,³ Gravestock et al., and Dillon et al. (no observed P – dependence at 297±1 K) while the temperature dependence reported by Nakano et al. is in conflict with the results of Gravestock et al. and Dillon et al.

- I76. S + O₂.** The recommended value for k(298 K) is the average of values reported by Fair and Thrush,⁵ Fair et al.,⁶ Donovan and Little,⁴ Davis et al.,³ Clyne and Townsend,¹ Clyne and Whitefield,² Miyoshi et al.,⁸ and Lu et al.⁷ The recommended value for E/R is the average of E/R values obtained from the data sets of Davis et al. (25 Torr CO₂, 252–423 K, E/R = +1 K), Davis et al. (20–200 Torr He, 298–422 K, E/R = –204 K), Clyne and Whitefield (~1 Torr Ar, 296–393 K, E/R = –129 K), and Lu et al. (50 Torr Ar, 298–505 K, E/R = –66 K). Lu et al. report non-Arrhenius behavior at T > 505 K. A theoretical analysis by Lu et al. suggests that reaction occurs almost exclusively via a SOO(¹A') intermediate at T < 500 K, whereas other channels involving SOO(¹A'') as an intermediate and formation of SOO(³A'') followed by isomerization to SO₂ before dissociation, become important at higher temperatures and account for the observed rapid increase of the rate constant with increasing temperature above 500 K. High temperature kinetic data reported by Saito et al.⁹ (1900–2200 K), Tsuchiya et al. (980–1610 K),¹⁰ and Woiki and Roth (1200–3500 K)¹¹ are reasonably consistent with the rate constants predicted theoretically by Lu et al.

- I77. S + O₃.** This recommendation accepts the only available experimental data of Clyne and Townsend.¹ In this study the authors measure a value of the rate constant for S + O₂ in reasonable agreement with that recommended above.
(Table: 82-57, Note: 82-57, Evaluated: 82-57) [Back to Table](#)
- (1) Clyne, M. A. A.; Townsend, L. W. Rate constant measurements for rapid reactions of ground state sulphur 3p⁴(³P_g) atoms. *Int. J. Chem. Kinet.* **1975**, *Symp. 1*, 73-84.
- I78. SO + O₂.** The recommended E/R is the average of values reported by Black et al. (E/R = 2370 K, 250–420 K)¹ and Schurath and Goede (E/R = 2180 K, 262–363 K),⁵ while the recommended k(298 K) is the average of values computed from the Arrhenius expressions reported in the same two studies. The room temperature rate constant obtained from the Black et al. study¹ supersedes an earlier value¹ as recommended by the authors. The recommended values for k(T) lie significantly higher than an extrapolation of the higher temperature data of Homann et al.,⁴ but are consistent with the more recent high temperature study of Garland.³ A room temperature upper limit on k set by Breckenridge and Miller² is consistent with the recommendation.

181. $\text{SO} + \text{OCIO}$. This recommendation is based on the room temperature study by Clyne and MacRobert.¹ The uncertainty reflects the absence of any confirming investigation.

(Table: 82-57, Note: 82-57, Evaluated: 82-57) [Back to Table](#)

- (1) Clyne, M. A. A.; MacRobert, A. J. Kinetic studies of free radical reactions by mass spectrometry. II. The reactions of $\text{SO} + \text{ClO}$, $\text{SO} + \text{OCIO}$ and $\text{SO} + \text{BrO}$. *Int. J. Chem. Kinet.* **1981**, *13*, 187-197.

182. $\text{SO}_3 + 2 \text{H}_2\text{O}$. Several research groups have attempted to quantify the rate of sulfuric acid formation via this reaction in the gas phase. Reiner and Arnold⁶ placed an upper limit of $2.4 \times 10^{-15} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ on the rate constant, slightly lower than that determined by Wang et al.⁸ The inability to cite the results as other than an upper limit is due to the difficulty in excluding all heterogeneous effects from the experiments. The higher rate constant reported earlier by Castleman et al.¹ may have resulted from an underestimation of the effects of such heterogeneous reactions. Subsequently, Reiner and Arnold⁷ sought to improve their rate constant determination by more detailed quantification of heterogeneous contributions. They derived a value of $1.2 \times 10^{-15} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$, independent of pressure (from 31–260 mbar of synthetic air). Evidence was also obtained that H_2SO_4 was, indeed, the product of the reaction.

Kolb et al.³ attempted to measure the gas phase rate constant using a turbulent flow reactor designed to minimize wall effects. Their results, when analyzed as representing a bimolecular reaction, support a rate constant in the range $(1-7) \times 10^{-15} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$. However, a more detailed analysis of the data indicated that the gas phase reaction was second order in water vapor. The reaction rate was also observed to increase as the temperature was lowered from 333 K to 243 K. These observations, together with calculations by Morokuma and Mugurama,⁵ led the latter authors to suggest that SO_3 consumption likely involved its reaction with the water dimer or the reaction $\text{SO}_3 + \text{H}_2\text{O} + \text{H}_2\text{O}$, leading to the formation of sulfuric acid.

A laminar flow reactor study by Lovejoy et al.⁴ over the temperature range 250 to 360 K also revealed SO_3 loss to be second order in water concentration and independent of pressure (from 20 to 80 Torr of N_2 at 300 K). These latter authors measured a strong negative temperature dependence for the rate constant and a significant kinetic isotope effect ($k_{\text{H}_2\text{O}} \approx 2k_{\text{D}_2\text{O}}$), leading them to describe the reaction as proceeding via the rapid association between SO_3 and H_2O followed by a slower reaction between the adduct and water to form sulfuric acid. Lovejoy et al.'s measurement of a -54 kJ mol^{-1} "activation" energy was viewed as energetically inconsistent with a $\text{SO}_3 + \text{water dimer}$ reaction mechanism since it would require a large negative activation energy for the $\text{SO}_3 + (\text{H}_2\text{O})_2$ step. Jayne et al.² have carried out a turbulent flow reactor study over the temperature range 283 to 370 K and the pressure range 100 to 760 Torr N_2 . Their results provide further support for a mechanism involving formation of an $\text{SO}_3 + \text{H}_2\text{O}$ adduct that reacts with a second H_2O to form H_2SO_4 , and the rate constants they report agree quite well with those reported by Lovejoy et al. The recommended expression for first order loss of SO_3 ,

$$k^1 = 8.5 \times 10^{-41} \exp(+6540/T) [\text{H}_2\text{O}]^2 \text{ s}^{-1} \quad ([\text{H}_2\text{O}] \text{ in molecules cm}^{-3})$$

is the best fit of the combined data of Lovejoy et al. and Jayne et al. to an Arrhenius form.

- I84. $\text{SH} + \text{O}_2$.** This upper limit for $k(298 \text{ K})$ is based on the study by Stachnik and Molina⁶ utilizing experiments sensitive to the production of OH. Somewhat higher upper limits of 1.0×10^{-17} and $1.5 \times 10^{-17} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ were assigned by Friedl et al.³ and Wang et al.⁸ respectively from the sensitivities for OH detection and SH decay respectively. An even higher upper limit by Black,² based on the lack of SH decay, may have been complicated by SH regeneration. Much less sensitive upper limits have been calculated by Tsee et al.,⁷ ¹⁸ $\text{cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ for the rate constant for the sum of the two $\text{SH} + \text{O}_2$ reaction channels (producing OH + SO and H + SO_2). The HSO_2 potential energy surface has been studied theoretically by Ballester and Varandas,¹ Garrido et al.,⁴ Resende and Ornellas,⁵ and Zhou, et al.⁹ Resende and Ornellas and Zhou et al. predict that at atmospheric temperatures (i) OH + SO are the dominant bimolecular products and (ii) the rate constant is orders of magnitude slower than the upper limit reported by Stachnik and Molina.

- I85. $\text{SH} + \text{O}_3$.** The value for $k(298 \text{ K})$ is an average of the determinations by Friedl et al.¹ (laser induced fluorescence detection of SH), Schonle et al.⁴ (mass spectrometric detection of reactant SH and product HSO) as revised by Schindler and Benter,³ and Wang and Howard⁵ (laser magnetic resonance detection of SH). The temperature dependence is from Wang and Howard with the A-factor calculated to agree with the recommended value for $k(298 \text{ K})$. The recommendation for g reflects the fact that the temperature dependence comes from measurements above room temperature and, thus, extrapolation to lower temperatures may be subject to additional uncertainties. Wang and Howard report observing a minor reaction channel that produces $\text{H} + \text{SO} + \text{O}_2$. A theoretical study by Resende and Ornellas² concludes that if reaction occurs on the ground state potential energy surface, the rate constant should be several orders of magnitude slower than the experimental value.

- I86. SH + H₂O₂.** This recommended upper limit for k(298 K) is based on the study of Friedl et al.¹ Their value is calculated from the lack of SH decay (measured by laser induced fluorescence) and the lack of OH production (measured by resonance fluorescence). The three possible product channels are H₂S + HO₂, HSOH + OH, and HSO + H₂O.
(Table: 85-37, Note: 85-37, Evaluated: 85-37) [Back to Table](#)
- (1) Friedl, R. R.; Brune, W. H.; Anderson, J. G. Kinetics of SH with NO₂, O₃, O₂, and H₂O₂. *J. Phys. Chem.* **1985**, *89*, 5505-5510, doi:10.1021/j100271a038.
- I87. SH + NO₂.** The recommendation is based on the temperature-dependent measurements of Wang et al.¹⁰ and Herndon and Ravishankara.⁵ All data points in each study were scaled by a factor equal to the ratio k(298 K)_{Arr}/k(298 K)_{ave} where k(298 K)_{Arr} is the 298 K rate constant obtained from the best fit Arrhenius expression describing the individual T-dependent data set and k(298 K)_{ave} is the average of the k(298 K)_{Arr} values from the two studies. The best fit of the scaled data to $\ln k = \ln A - E/RT$ is recommended. Wang et al. suggest that the lower values of k(298 K) reported by Black,¹ Friedl et al.,⁴ and Bulatov et al.² are due to SH regeneration from the H₂S source compound. Herndon and Ravishankara suggest that simultaneous detection of SH and SO may have corrupted earlier studies where laser induced fluorescence was employed as the detection technique.^{1,4} In the study by Stachnik and Molina,⁹ attempts were made at minimizing SH regeneration, and the reported value of k(298 K) was significantly greater than that from the earlier studies, but still 30% less than that measured by Wang et al., who used two independent SH source reactions. A slightly larger rate constant measured by Schonle et al.,⁸ as revised by Schindler and Benter,⁷ is not recommended due to the somewhat more limited database for their determination. The reaction as written represents the most exothermic channel. In fact, HSO has been detected as a product by Leu and Smith,⁶ Bulatov et al.,² Schonle et al.,⁸ and Wang et al. The absence of a primary deuterium isotope effect, as observed by both Wang et al. and Herndon and Ravishankara, coupled with the large magnitude of the rate constant suggests that the (four-center intermediate) channels producing SO + HNO and OH + SNO are of minor importance. No evidence for a three-body combination reaction was found by either Black or Friedl et al. Based on a pressure independence of the rate constant between 30 and 300 Torr, Black set an upper limit of $7.0 \times 10^{-31} \text{ cm}^6 \text{ molecule}^{-2} \text{ s}^{-1}$ for the termolecular rate constant. Similarly, Stachnik and Molina⁹ observed no change in decay rate between 100 and 730 Torr with O₂ (although these O₂ experiments were designed primarily to limit SH regeneration). The recommendation given here is supported by the discharge flow laser induced fluorescence study of the SD + NO₂ reaction by Fenter and Anderson.³ These investigators report a 298 K rate constant of $6.8 \times 10^{-11} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$, which compares favorably with the values of 7.3×10^{-11} and $6.6 \times 10^{-11} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ determined by Wang et al. and Herndon and Ravishankara, respectively, in studies of the same reaction. Fenter and Anderson also obtained an E/R value of -210 K, very similar to the -279 K value derived by Herndon and Ravishankara for the SD reaction and the values -240 K and -270 K derived by Wang et al. and Herndon and Ravishankara, respectively, for the SH reaction.

- I88. SH + N₂O.** The recommendation is the upper limit rate constant reported by Herndon et al.¹ As discussed by Herndon et al., the much greater (four orders of magnitude) rate constant reported by Ravichandran et al.² appears to result from mis-interpretation of the source of electronically excited HSO, chemiluminescence from which was employed by Ravichandran et al. to follow the reaction kinetics.
(Table: 06-02, Note: 06-02, Evaluated: 06-2) [Back to Table](#)

- (2) Ravichandran, K.; Williams, R.; Fletcher, T. R. Atmospheric reactions of vibrationally excited greenhouse gases: SH + N₂O(*n*, 0, 0). *Chem. Phys. Lett.* **1994**, *217*, 375-380.
- I89. SH + Cl₂.** The recommended 298 K rate constant is based on the work of Nesbitt and Leone,² who studied the kinetics of the Cl + H₂S → SH + HCl, SH + Cl₂ → ClSH + Cl chain reaction. Fenter and Anderson¹ employed a discharge flow laser induced fluorescence technique to study the SD + Cl₂ reaction over the temperature range 273–373 K. The 298 K rate constant reported by Fenter and Anderson is about 20% greater than the one reported by Nesbitt and Leone, which is consistent with the expected secondary kinetic isotope effect. The recommended value of E/R is taken from the work of Fenter and Anderson; the recommended value for the parameter *g* reflects the absence of confirming studies and uncertainty in the isotope effect on E/R.

- (1) Fenter, F. F.; Anderson, J. G. Kinetics and mechanism of the reactions of the SD Radical with Br₂, BrCl, Cl₂, and F₂. *J. Phys. Chem.* **1991**, *95*, 3172-3180.
- (2) Nesbitt, D. J.; Leone, S. R. Laser-initiated chemical chain reactions. *J. Chem. Phys.* **1980**, *72*, 1722-1732.
- I90. SH + BrCl; SH + Br₂; SH + F₂.** The recommendations for these reactions are derived from the data of Fenter and Anderson¹ for the SD radical. The uncertainties have been increased over those estimated by the investigators to reflect the absence of any confirming investigations and the influence of the secondary isotope effect. For the BrCl reaction, the channel producing ClSD + Br was found to be described by the rate expression $k = 2.3 \times 10^{-11} \exp(100/T) \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$.
(Table: 92-20, Note: 06-2, Evaluated: 92-20) [Back to Table](#)
- (1) Fenter, F. F.; Anderson, J. G. Kinetics and mechanism of the reactions of the SD Radical with Br₂, BrCl, Cl₂, and F₂. *J. Phys. Chem.* **1991**, *95*, 3172-3180.
- I91. HSO + O₂.** This recommendation is based on the study by Lovejoy et al.,² who employed laser magnetic resonance monitoring of HSO in a discharge flow system. The upper limit thus derived for *k*(298 K) is nearly two orders of magnitude smaller than measured by Bulatov et al.¹
(Table: 92-20, Note: 92-20, Evaluated: 92-20) [Back to Table](#)
- (1) Bulatov, V. P.; Sarkisov, O. M.; Kozliner, M. Z.; Ergorov, V. G. Mechanism of hydrogen sulfide photooxidation in atmosphere. *Khim. Fiz.* **1986**, *5*, 1031-1036.
- (2) Lovejoy, E. R.; Wang, N. S.; Howard, C. J. Kinetic studies of the reactions of HSO with NO₂, NO, and O₂. *J. Phys. Chem.* **1987**, *91*, 5749-5755.
- I92. HSO + O₃.** This recommended value for *k*(298 K) is based on the determinations by Friedl et al.¹ and Wang and Howard.³ In the first study, performed at higher O₃ concentrations, greater quantities of HSO were produced in the flow tube and SH approached a steady state due to its generation via HSO + O₃. The rate constant for this reaction was thus determined relative to SH + O₃ from measurements of the steady state SH concentration as a function of the initial SH concentration. In the second study, the rate constant and its branching ratio were measured at two temperatures. At room temperature, the overall rate constant is in excellent agreement with that of Friedl et al. More recently, Lee et al.² determined a room temperature rate constant of $4.7 \times 10^{-14} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ for the sum of all reaction channels not producing HS. This value is approximately 30% greater than that measured by Wang and Howard for the same channels. Lee et al. derive

an Arrhenius activation energy of 1120 K for these channels from data between 273 and 423 K, in agreement with the more limited temperature-dependent data of Wang and Howard.

The lack of an isotope effect when SD was employed in the Friedl et al. study suggests that the products of the $\text{HSO} + \text{O}_3$ reaction are $\text{SH} + 2\text{O}_2$ (analogous to those for $\text{HO}_2 + \text{O}_3$). However, Wang and Howard found that only 70% of the reaction leads to HS formation. In addition, their observations of HO_2 production in the presence of O_2 suggests the existence of a reaction channel producing $\text{HSO}_2 + \text{O}_2$ followed by $\text{HSO}_2 + \text{O}_2 \rightarrow \text{HO}_2 + \text{SO}_2$. At the present time, no recommendation is given for the product channels. Further mechanistic work is suggested, since it is important to understand whether this reaction in the atmosphere leads to HS regeneration or to oxidation of the sulfur.

- (3) Wang, N. S.; Howard, C. J. Kinetics of the reactions of HS and HSO with O_3 . *J. Phys. Chem.* **1990**, 94, 8787-8794.

I93. $\text{HSO} + \text{NO}$; $\text{HSO} + \text{NO}_2$. The recommendations for these reactions are based on the study by Lovejoy et al.³ in which laser magnetic resonance was used to monitor HSO in a discharge flow system. Their upper limit for the NO reaction is a factor of 25 smaller than the rate constant measured by Bulatov et al.² using intracavity laser absorption at pressures between 10 and 100 Torr. Since it is unlikely that this reaction rate undergoes a factor of 25 increase between 1 Torr (the pressure of the Lovejoy et al. work) and 10 Torr, the higher rate constant may be due to secondary chemistry associated with the HSO production methods employed.

The recommendation for the NO_2 reaction is a factor of 2 higher than the rate constant reported by Bulatov et al.¹ Lovejoy et al. have attributed this difference to HSO regeneration under the experimental conditions used by Bulatov et al.¹ The product assignment for this reaction is discussed in the note for the $\text{HSO}_2 + \text{O}_2$ reaction.

- (1) Bulatov, V. P.; Kozliner, M. Z.; Sarkisov, O. M. Determination of rate constants for the reactions of $\text{SH} + \text{NO}_2 \rightarrow \text{HSO} + \text{NO}$ and $\text{HSO} + \text{NO}_2 \rightarrow$ products. *Khim. Fiz.* **1984**, 3, 1300-1305.
- (2) Bulatov, V. P.; Kozliner, M. Z.; Sarkisov, O. M. Reactions of SH and HSO radicals with nitrogen oxide. *Khim. Fiz.* **1985**, 4, 1353-1357.
- (3) Lovejoy, E. R.; Wang, N. S.; Howard, C. J. Kinetic studies of the reactions of HSO with NO_2 , NO, and O_2 . *J. Phys. Chem.* **1987**, 91, 5749-5755.

I94. $\text{HSO}_2 + \text{O}_2$. This recommendation is based on the rate of HO_2 formation measured by Lovejoy et al.¹ upon addition of O_2 to the $\text{HSO} + \text{NO}_2$ reaction system. While HSO_2 was not observed directly, a consideration of the mechanistic possibilities for $\text{HSO} + \text{NO}_2$, coupled with measurements of the HO_2 production rate at various O_2 pressures, led these authors to suggest that HSO_2 is both a major product of the $\text{HSO} + \text{NO}_2$ reaction and a precursor for HO_2 via reaction with O_2 .

(Table: 87-41, Note: 87-41, Evaluated: 87-41) [Back to Table](#)

- (1) Lovejoy, E. R.; Wang, N. S.; Howard, C. J. Kinetic studies of the reactions of HSO with NO_2 , NO, and O_2 . *J. Phys. Chem.* **1987**, 91, 5749-5755.

I95. $\text{HOSO}_2 + \text{O}_2$. This recommendation is based on the studies of Gleason et al.³ and Gleason and Howard² in which the HOSO_2 reactant was monitored using a chemical ionization mass spectrometric technique. Gleason and Howard conducted their measurements over the 297–423 K temperature range in the only temperature dependence investigation, and these authors report the same 297 K rate coefficient as the one reported by Gleason et al. The recommended uncertainty parameter g is increased from the E/R error limits quoted by Gleason and Howard to account for potential uncertainties in extrapolating their data to sub-ambient temperatures. The recommended value of $k(298 \text{ K})$ derives further support from the studies of Margitan⁵ and Martin et al.,⁶ both of whom used modeling fits of OH radical decays in the $\text{OH} + \text{SO}_2 + \text{M}$ reaction system in the presence of O_2 and NO. In this latter analysis, the HOSO_2 reacts with O_2 , yielding HO_2 , which subsequently regenerates OH through its reaction with NO. The infrared spectrum of HOSO_2 has been recorded in low temperature matrix isolation experiments by Hashimoto et al.⁴ and Nagase et al.⁷ Mass spectrometric detection of HOSO_2 in the gas phase has also been reported by Egsgaard et al.¹

I96. $\text{CS} + \text{O}_2$. The recommendation given for $k(298 \text{ K})$ is based on the work of Black et al.¹ using laser induced fluorescence to monitor CS. This value agrees with the somewhat less precise determination by Richardson² using OCS formation rates. The latter author presents evidence that this reaction channel dominates over the one producing $\text{SO} + \text{CO}$ by more than a factor of 10. Measurements by Richardson at 293 K and 495 K yield an E/R of 1860 K. However, use of this activation energy with the recommended value of $k(298 \text{ K})$ results in an unusually low Arrhenius A-factor of $1.5 \times 10^{-16} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$. In view of this, no recommendation is given for the temperature dependence.

- (2) Richardson, R. J. CS- O_2 flame reaction chemistry. *J. Phys. Chem.* **1975**, 79, 1153-1158.

I97. $\text{CS} + \text{O}_3$; $\text{CS} + \text{NO}_2$. The $k(298 \text{ K})$ recommendations for both reactions accept the results of Black et al.,¹ who used laser-induced fluorescence to monitor the CS reactant in a room temperature experiment. The uncertainty factors reflect the absence of any confirming measurements.

- (1) Black, G.; Jusinski, L. E.; Slinger, T. G. Rate coefficients for CS reactions with O_2 , O_3 and NO_2 at 298 K. *Chem. Phys. Lett.* **1983**, 102, 64-68.

I98. $\text{CH}_3\text{S} + \text{O}_2$. This upper limit is based on the study by Tyndall and Ravishankara.³ Somewhat higher upper limits were derived in the earlier studies of Balla et al.¹ and Black and Jusinski.²

(Table: 90-1, Note: 90-1, Evaluated: 90-1) [Back to Table](#)

- (1) Balla, R. J.; Nelson, H. H.; McDonald, J. R. Kinetics of the reaction of CH_3S with NO , NO_2 and O_2 . *Chem. Phys.* **1986**, 109, 101-107.

I99. $\text{CH}_3\text{S} + \text{O}_3$. The recommendation for $k(298 \text{ K})$ is the average of room temperature rate constants reported by Tyndall and Ravishankara,⁵ Domine et al.,² Turnipseed et al.,⁴ and Martinez et al.³ The recommendation for E/R is the average of values obtained from least squares fits of the temperature-dependent data of Turnipseed et al. and Martinez et al. using only rate constants at temperatures below 345 K. A failure to observe significant reaction in the study by Black and Jusinski¹ is interpreted as due to rapid regeneration of CH_3S in their system. Tyndall and Ravishankara⁵ corrected their measured 298 K rate constant downward by ~20% to account for CH_3S regeneration via the $\text{CH}_3\text{SO} + \text{O}_3$ reaction, but the magnitude of the correction is now highly uncertain in light of the results of Domine et al. and Turnipseed et al. Domine et al. measured the yield of CH_3SO to be 15%.

I101. CH₃S + NO₂. The recommendation for k(298 K) is the average of room temperature rate constants reported by Tyndall and Ravishankara,⁶ Domine et al.,³ Turnipseed et al.,⁵ Martinez et al.,⁴ and Chang et al.² The recommendation for E/R is the average of values reported by Turnipseed et al., Martinez et al., and Chang et al. An earlier study by Balla et al.¹ appears to have been affected by secondary reactions resulting from high radical concentrations. Tyndall and Ravishankara determined the NO yield to be (80 ± 20)%. Together with the unity yield of CH₃SO obtained by Domine et al., this implies that the primary reaction channel is as written.

I102. CH₃S + CO. The recommendation is based on the study of Koch et al.,¹ who generated CH₃S by laser flash photolysis of CH₃SSCH₃ and monitored the loss of CH₃S by laser induced fluorescence. The rate of loss of CH₃S was found to be independent of [CO] up to levels of approximately 10¹⁷ molecules cm⁻³. No enhancement of the CH₃S loss rate was observed when O₂ was added to the reaction mixture, confirming that CH₃SOO is also unreactive toward CO. Electronic structure calculations are consistent with experimental observations, suggesting that there is a significant barrier (~12 kJ mol⁻¹) to formation of a very weakly bound (~9 kJ mol⁻¹) CH₃S-CO adduct.

I103. CH₃S + Br₂. The recommendation is based on the study of Nicovich et al.,¹ who coupled laser flash photolysis of Br₂/CH₃SH/H₂/N₂ mixtures with resonance fluorescence detection of Br atoms to monitor the kinetics of Br approach to steady state (Br + CH₃SH → CH₃S + HBr; CH₃S + Br₂ → CH₃SBr + Br). The recommended uncertainty is larger than estimated by Nicovich et al. to reflect the slightly indirect nature of the rate constant determination and the lack of a confirming study.

- I104. $\text{CH}_2\text{SH} + \text{O}_2$.** This recommended value for $k(298\text{ K})$ is the average of the rate constants obtained by Rahman et al.² in a fast flow mass spectrometry system and Anastasi et al.¹ using a pulse radiolysis – kinetic absorption apparatus. The value of Anastasi et al. is nearly twice that of Rahman et al. It is difficult at present to indicate a preference for the results of one study over the other, and the value of $f(298\text{ K})$ has been chosen to reflect this uncertainty. Since this is a fast bimolecular reaction, one would expect the products to be $\text{HO}_2 + \text{CH}_2\text{S}$, by analogy with the reaction between CH_2OH and O_2 .

- I108. $\text{CH}_3\text{SO} + \text{O}_3$.** The recommended value for $k(298\text{ K})$ is an average of values reported by Domine et al.² and Borissenko et al.¹ It is supported by the study of Tyndall and Ravishankara,³ in which the rate constant was derived from a complex analysis of the $\text{CH}_3\text{S} + \text{O}_3$ reaction system. Borissenko et al. measured the rate constant relative to the rate constant for the $\text{CH}_3\text{SO} + \text{NO}_2$ reaction; they report that the $\text{CH}_3\text{SO} + \text{NO}_2$ rate constant is greater by a factor of 47. Domine et al. place the direct yield of CH_2SO at approximately 10% and that of CH_3S at 13% at low pressure. Borissenko et al. report that the SO_2 yield is near unity in 100–600 Torr N_2 .
(Table: 06-2, Note: 06-2, Evaluated: 06-2) [Back to Table](#)

I109. CH₃SO + NO₂. This recommendation is based on the direct measurements of Domine et al.² The results are supported by somewhat less direct measurements of Tyndall and Ravishankara,⁶ Mellouki et al.,⁵ and Kukui et al.³ The results of Kukui et al. suggest a small negative activation energy, but their data set is not extensive enough to warrant a recommendation for E/R without independent confirmation. Borissenko et al.¹ report that the SO₂ yield drops from ~0.4 in 100 Torr N₂ to ~0.25 in 660 Torr N₂. A detailed theoretical singlet potential energy surface has been reported by Lesar.⁴

I110. CH₃SOO + O₃, CH₃SOO + NO, CH₃SOO + NO₂. These recommendations are based on the experiments of Turnipseed et al.¹ in which CH₃S was monitored by laser induced fluorescence in equilibrium with CH₃SOO. The upper limit for the O₃ reaction was determined from experiments at 227 K. The results for the NO and NO₂ reactions were independent of temperature over the ranges 227–256 K and 227–246 K, respectively. The uncertainties placed on these recommendations have been increased over those estimated by the authors to reflect the absence of any confirming investigations.

(Table: 94-26, Note: 94-26, Evaluated: 94-26) [Back to Table](#)

- (1) Turnipseed, A. A.; Barone, S. B.; Ravishankara, A. R. Reactions of CH₃S and CH₃SOO with O₃, NO₂, and NO. *J. Phys. Chem.* **1993**, *97*, 5926-5934.

I111. CH₃SO₂ + NO₂. This recommendation is based on the study by Ray et al.¹ using a discharge flow reactor equipped with laser induced fluorescence and mass spectrometric detection. The CH₃SO₂ was produced by the sequential oxidation of CH₃S and CH₃SO by NO₂ and is to be differentiated from the weakly bound adduct, CH₃SOO, formed by the reaction of CH₃S with O₂ at low temperature (Turnipseed et al.²). The uncertainty limit on the rate constant has been increased over that given by the authors to reflect the absence of any confirming investigation. However, some additional support for this recommendation does come from the study of the CH₃S + NO₂ reaction by Tyndall and Ravishankara.³ These authors observed fluorescence from a product species tentatively identified as CH₃SO₂, produced by the reaction of CH₃SO with NO₂. Computer simulation of the rise and fall of the fluorescence signal yielded an approximate rate constant value for the reaction CH₃SO₂ + NO₂ of $7.0 \times 10^{-12} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$. However, an unambiguous differentiation between the production and disappearance rate constants was not possible.

(Table: 97-4, Note: 97-4, Evaluated: 97-4) [Back to Table](#)

- (1) Ray, A.; Vassalli, I.; Laverdet, G.; Le Bras, G. Kinetics of the thermal decomposition of the CH₃SO₂ radical and its reaction with NO₂ at 1 Torr and 298 K. *J. Phys. Chem.* **1996**, *100*, 8895-8900, doi:10.1021/jp9600120.
- (2) Turnipseed, A. A.; Barone, S. B.; Ravishankara, A. R. Reactions of CH₃S and CH₃SOO with O₃, NO₂, and NO. *J. Phys. Chem.* **1993**, *97*, 5926-5934.
- (3) Tyndall, G. S.; Ravishankara, A. R. Kinetics and mechanism of the reactions of CH₃S with O₂ and NO₂ at 298 K. *J. Phys. Chem.* **1989**, *93*, 2426-2435.

I112. CH₃SCH₂ + NO₃. The recommended value for k(298 K) is based on the experiments of Butkovskaya and Le Bras.¹ The uncertainty factor reflects the absence of any confirming investigation.

(Table: 94-26, Note: 94-26, Evaluated: 94-26) [Back to Table](#)

- (1) Butkovskaya, N. I.; Le Bras, G. Mechanism of the $\text{NO}_3 + \text{DMS}$ reaction by discharge flow mass spectrometry. *J. Phys. Chem.* **1994**, *98*, 2582-2591, doi:10.1021/j100061a014.

I113. $\text{CH}_3\text{SCH}_2\text{O}_2 + \text{NO}$. The recommended 298 K rate constant is based on the experiments of Urbanski et al.,² which are less impacted by secondary chemistry complications than the experiments of Wallington et al.³ or Turnipseed et al.,¹ the error limits are chosen to encompass the rate constants reported in all three studies. The E/R value is taken from Urbanski et al., who report the only available temperature dependence data. The recommended value for the parameter g is larger than reported by Urbanski et al. pending independent confirmation of their result. Theoretical work by Wu et al.⁴ suggests that isomerization of $\text{CH}_3\text{SCH}_2\text{O}_2$ to $\text{CH}_2\text{SCH}_2\text{OOH}$ can compete with $\text{CH}_3\text{SCH}_2\text{O}_2$ bimolecular reactions with NO , HO_2 , and RO_2 under tropospheric conditions. Urbanski et al. observed that the reaction produces formaldehyde (H_2CO) with unit yield, suggesting that the $\text{CH}_3\text{SCH}_2\text{O}$ product rapidly decomposes to $\text{CH}_3\text{S} + \text{H}_2\text{CO}$.

I114. $\text{CH}_3\text{SCH}_2\text{O}_2 + \text{CH}_3\text{SCH}_2\text{O}_2$. The recommended 298 K rate constant is the average of values reported by Wallington et al.² using a pulse radiolysis UV absorption technique and Urbanski et al.¹ using a laser flash photolysis tunable diode laser absorption technique. Urbanski et al. observed that the reaction produces formaldehyde with unit yield, suggesting that the dominant reaction pathway is $2 \text{CH}_3\text{SCH}_2\text{O}_2 \rightarrow 2 \text{CH}_3\text{SCH}_2\text{O} + \text{O}_2$ ($\text{CH}_3\text{SCH}_2\text{O}$ rapidly decomposes to $\text{CH}_3\text{S} + \text{H}_2\text{CO}$).

- (2) Wallington, T. J.; Ellermann, T.; Nielsen, O. J. Atmospheric chemistry of dimethyl sulfide: UV spectra and self-reaction kinetics of CH_3SCH_2 and $\text{CH}_3\text{SCH}_2\text{O}_2$ radicals and kinetics of the reactions $\text{CH}_3\text{SCH}_2 + \text{O}_2 \rightarrow \text{CH}_3\text{SCH}_2\text{O}_2 + \text{NO}$ and $\text{CH}_3\text{SCH}_2\text{O}_2 + \text{NO} \rightarrow \text{CH}_3\text{SCH}_2\text{O} + \text{NO}_2$. *J. Phys. Chem.* **1993**, *97*, 8442-8449.

I115. $\text{CH}_3\text{SS} + \text{O}_3$. The recommended value for $k(298 \text{ K})$ is based on the discharge flow photoionization mass spectrometry study by Domine et al.¹ The uncertainty factor reflects the absence of any confirming investigations. The rate constant ratio for the reactions of CH_3SS with O_3 and NO_2 is consistent with the rate constant ratio for the corresponding CH_3S reactions.

I116. $\text{CH}_3\text{SS} + \text{NO}_2$; $\text{CH}_3\text{SSO} + \text{NO}_2$. The recommended values for $k(298 \text{ K})$ are based on the discharge flow photoionization mass spectrometry study by Domine et al.¹ The rate constant ratio for these two reactions agrees with that observed for reactions of other RS/RSO radicals with NO_2 . The assigned uncertainties reflect this agreement but acknowledge the absence of any confirming investigation. In the Domine et al. study, CH_3SSO was produced by reacting away all CH_3SS with high NO_2 concentrations. Thus, as expected, O atom transfer may be the primary channel in the CH_3SS reaction.

1.15 Metal Reactions

1.15.1 Table 1J: Metal Reactions

Reaction	Temperature Range of Exp. Data (K) ^a	A-Factor	E/R	k(298 K) ^b	f(298 K) ^c	g	Notes
$\text{Na} + \text{O}_2 \xrightarrow{\text{M}} \text{NaO}_2$		(See Table 2-1)					
$\text{Na} + \text{O}_3 \rightarrow \text{NaO} + \text{O}_2$ $\rightarrow \text{NaO}_2 + \text{O}$	208–377	1.0×10^{-9}	95	7.3×10^{-10} $< 4.0 \times 10^{-11}$	1.2	50	J 1
$\text{Na} + \text{N}_2\text{O} \rightarrow \text{NaO} + \text{N}_2$	240–850	2.8×10^{-10}	1600	1.3×10^{-12}	1.2	400	J 2
$\text{Na} + \text{Cl}_2 \rightarrow \text{NaCl} + \text{Cl}$	294	7.3×10^{-10}	0	7.3×10^{-10}	1.3	200	J 3
$\text{NaO} + \text{O} \rightarrow \text{Na} + \text{O}_2$	290–573	4.4×10^{-10}	0	4.4×10^{-10}	1.5	200	J 4
$\text{NaO} + \text{O}_2 \xrightarrow{\text{M}} \text{NaO}_3$		(See Table 2-1)					
$\text{NaO} + \text{O}_3 \rightarrow \text{NaO}_2 + \text{O}_2$ $\rightarrow \text{Na} + 2\text{O}_2$	207–377 296	1.1×10^{-9} 6.0×10^{-11}	570 0	1.6×10^{-10} 6.0×10^{-11}	1.5 3.0	300 800	J 5
$\text{NaO} + \text{H}_2 \rightarrow \text{NaOH} + \text{H}$	296	2.6×10^{-11}	0	2.6×10^{-11}	2.0	600	J 6
$\text{NaO} + \text{H}_2\text{O} \rightarrow \text{NaOH} + \text{OH}$	260–716	4.3×10^{-10}	500	8.0×10^{-11}	1.5	200	J 7
$\text{NaO} + \text{NO} \rightarrow \text{Na} + \text{NO}_2$	296	1.5×10^{-10}	0	1.5×10^{-10}	4.0	400	J 8
$\text{NaO} + \text{CO}_2 \xrightarrow{\text{M}} \text{NaCO}_3$		(See Table 2-1)					
$\text{NaO} + \text{HCl} \rightarrow \text{products}$	308	2.8×10^{-10}	0	2.8×10^{-10}	3.0	400	J 9
$\text{NaO}_2 + \text{O} \rightarrow \text{NaO} + \text{O}_2$	300	2.2×10^{-11}	0	2.2×10^{-11}	5.0	600	J 10
$\text{NaO}_2 + \text{NO} \rightarrow \text{NaO} + \text{NO}_2$	296			$< 10^{-14}$			J 11
$\text{NaO}_2 + \text{HCl} \rightarrow \text{products}$	295	2.3×10^{-10}	0	2.3×10^{-10}	3.0	400	J 12
$\text{NaOH} + \text{HCl} \rightarrow \text{NaCl} + \text{H}_2\text{O}$	308	2.8×10^{-10}	0	2.8×10^{-10}	3.0	400	J 13
$\text{NaHCO}_3 + \text{H} \rightarrow \text{Na} + \text{H}_2\text{O} + \text{CO}_2$	227–307	1.4×10^{-11}	1000	5×10^{-13}	2.0	100	J 14
$\text{NaOH} + \text{CO}_2 \xrightarrow{\text{M}} \text{NaHCO}_3$		(See Table 2-1)					

Shaded areas indicate changes or additions since JPL10-6. Italicized entries in blue denote estimates.

^a Temperature range of available experimental data. This is not necessarily the range of temperature over which the recommended Arrhenius parameters are applicable. See the corresponding note for each reaction for such information.

^b Units are $\text{cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$.

^c $f(298 \text{ K})$ is the uncertainty factor at 298 K. To calculate the uncertainty at other temperatures, use the expression:

$$f(T) = f(298 \text{ K}) \exp \left| g \left(\frac{1}{T} - \frac{1}{298} \right) \right|, \text{ note that the exponent is an absolute value.}$$

1.15.2 Notes: Metal Reactions

- J1. Na + O₃.** The recommendation is based on the measurements of Ager et al.,¹ Worsnop et al.⁶ as corrected in Worsnop et al.,⁷ and Plane et al.³ The data of Worsnop et al. supersede earlier work from that laboratory (Silver and Kolb⁵). Measurements made by Husain et al.² at 500 K are somewhat lower, probably because they did not recognize that secondary chemistry, NaO + O₃ → Na + 2O₂, interferes with the rate coefficient measurement. The temperature dependence is from results of Worsnop et al.⁷ (214–294 K) and Plane et al.³ (208–377 K). Ager et al.¹ estimate that the NaO₂ + O product channel is ≤5%. Evidence that the NaO product is in the ²Σ⁺ excited electronic state was reported by Shi et al.⁴ and Wright et al.⁸ (Table: 94-26, Note: 94-26, Evaluated: 94-26) [Back to Table](#)

- J2. Na + N₂O.** The recommendation incorporates the data of Husain and Marshall,³ Ager et al.,¹ Plane and Rajasekhar,⁴ and Worsnop et al.⁶ Silver and Kolb⁵ measured a rate coefficient at 295 K that is lower and is superseded by Worsnop et al. Helmer and Plane² report a measurement at 300 K in excellent agreement with the recommendation. Earlier, less direct studies are discussed by Ager et al.¹ The NaO product does not react significantly with N₂O at room temperature [*k* (for Na + N₂ + O₂ products) ≤ 10⁻¹⁶ cm³ molecule⁻¹ s⁻¹ and *k* (for NaO₂ + N₂ products) ≤ 2 × 10⁻¹⁵ cm³ molecule⁻¹ s⁻¹ (Ager et al.)]. Wright et al.⁷ used UV photoelectron spectroscopy to determine the product NaO is formed predominantly in the excited ²Σ⁺ state. (Table: 92-20, Note: 94-26, Evaluated: 94-26) [Back to Table](#)

- J3. Na + Cl₂.** Two measurements of the rate coefficient for this reaction are in excellent agreement: Silver¹ and Talcott et al.² The recommended value is the average of these room temperature results.
(Table 87-41, Note: 87-41, Evaluated: 87-41) [Back to Table](#)
- (1) Silver, J. A. Room temperature rate constant for the reaction of Na with Cl₂. *J. Chem. Phys.* **1986**, *84*, 4718-4720, doi:10.1063/1.450003.
 - (2) Talcott, C. L.; Ager, J. W., III; Howard, C. J. Gas phase studies of Na diffusion in He and Ar and kinetics of Na + Cl₂ and Na + SF₆. *J. Chem. Phys.* **1986**, *84*, 6161-6169, doi:10.1063/1.450757.
- J4. NaO + O.** The recommendation is based on measurements by Plane and Husain³ and Griffin et al.¹ The Na + O₃ reaction produces NaO predominately in the low lying A ²Σ⁺ state which can radiatively and collisionally decay slowly to the X ²Π ground state. The Plane and Husain³ experiment was configured so the the predominant reactant was NaO X ²Π while the Griffin et al.¹ experiment was designed to maximize NaO A ²Σ⁺ concentrations. While the two states may not have identical reaction rate constants, their energy difference is small compared to reaction exothermicity and both states show reaction rate constants near the collisional limit. Since this reaction in the atmosphere will probably proceed through a mixture of the two lowest NaO electronic states and data are available at only one temperature for each state, the recommended rate constant is an average of the two measurements. Plane and Husain³ reported that ~0.01 of the Na product is in the 3²P excited state, while Griffin et al.¹ report a Na 3²P product branching ratio of 0.14 ± 0.04. This difference is consistent with the orbital correlation predictions of products for reaction of each NaO state as presented by Herschbach et al.²

- J5. NaO + O₃.** This reaction was studied by Silver and Kolb,³ Ager et al.,¹ and Plane et al.,² who agree on the rate coefficient and branching ratio. This agreement may be fortuitous because Silver and Kolb used an indirect method and an analysis based on their rate coefficient for the Na + O₃ reaction, which is about 1/2 of the recommended value. Ager et al. employed a somewhat more direct measurement, but the study is complicated by a chain reaction mechanism in the Na/O₃ system. Plane et al. reported rate coefficient measurements for the NaO₂ + O₂ product channel over the temperature range 207–377 K using pulsed photolysis LIF methods. The recommendation for that channel is based on all three studies, and the recommendation for the Na + 2O₂ channel is based upon the results of Silver and Kolb and Ager et al. The latter reaction channel may also have a significant temperature dependence.

Tables

Table 2-1. Rate Constants for Termolecular Reactions	2-4
--	-----

2.1 Introduction

Rate constants for association reactions (Table 2) of the type $A + B \leftrightarrow [AB]^* \xrightarrow{M} AB$ can be pressure dependent. The low-pressure-limiting rate constants are given in the form:

$$k_o(T) = k_o^{300} \left(\frac{T}{300} \right)^{-n} \text{ cm}^6 \text{ molecule}^{-2} \text{ s}^{-1},$$

(where k_o^{300} has been adjusted for air as the third body). The limiting high-pressure rate constant is given in a similar form:

$$k_\infty(T) = k_\infty^{300} \left(\frac{T}{300} \right)^{-m} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}.$$

To obtain the effective second-order rate constant for a given condition of temperature and pressure (altitude), the following formula is used:

$$k_f([M], T) = \left(\frac{k_o(T)[M]}{1 + \frac{k_o(T)[M]}{k_\infty(T)}} \right) 0.6 \left\{ 1 + \left[\log_{10} \left(\frac{k_o(T)[M]}{k_\infty(T)} \right) \right]^2 \right\}^{-1}$$

The fixed value 0.6 that appears in this formula fits the data for all listed reactions adequately, although in principle this quantity may be different for each reaction, and also temperature dependent. There are rarely sufficient data to accommodate another parameter.

Some reactions that appear to be simple bimolecular processes proceed via bound intermediates. For example, the reaction between HO and CO to yield $H + CO_2$ takes place on a potential energy surface that contains the radical HOCO. The yield of H and CO_2 is diminished as the pressure rises. The loss of reactants is thus the sum of two processes, an association to yield HOCO and the chemical activation process yielding H and CO_2 . The total rate

constant for loss of reactants is fit by the equation above for the association added to the chemical activation rate constant which can be represented by a similar looking equation:

$$k_f^{ca}([M], T) = \left(\frac{k_o(T)}{1 + \frac{k_o(T)}{k_\infty(T)[M]}} \right) 0.6 \left\{ 1 + \left[\log_{10} \left(\frac{k_o(T)}{k_\infty(T)[M]} \right) \right]^2 \right\}^{-1}$$

Thus, a compilation of rate constants requires the stipulation of the four parameters, $k_o(300)$, n , $k_\infty(300)$, and m . These can be found in Table 2. The discussion that follows outlines the general methods we have used in establishing this table, and the notes to the table discuss specific data sources. Recent advances in theory have allowed direct calculation of rate constants for some reactions using RRKM/Master Equation methods.

When sufficient and precise data exist for a given reaction, we have fit the data to the four parameter expression above. We have used theory as a guide whenever possible.

2.2 Low-Pressure-Limiting Rate Constant, $k_o^x(T)$

Troe¹⁷ has described a simple method for obtaining low-pressure-limiting rate constants. In essence this method depends on the definition:

$$k_o^x(T) \equiv \beta_x k_{o,sc}^x$$

Here sc signifies “strong” collisions, x denotes the bath gas, and β_x is an efficiency parameter ($0 < \beta_x < 1$), which provides a measure of energy transfer. The strong collision rate constant can be calculated with some accuracy from knowledge of molecular parameters available from experiment and more and more from theory.

The coefficient β_x is related to the average energy transferred in a collision with gas x , $\langle \Delta E \rangle_x$, via:

$$\frac{\beta_x}{(1 - \sqrt{\beta_x})} = \frac{\langle \Delta E \rangle_x}{F_E kT}$$

Notice that $\langle \Delta E \rangle$ is quite sensitive to β . F_E is the correction factor of the energy dependence of the density of states (a quantity of the order of 1.1 for most species of stratospheric interest).

For some of the reactions of possible stratospheric interest reviewed here, there exist data in the low-pressure limit (or very close thereto), and we have chosen to evaluate and unify this data by calculating $k_o^x(T)$ for the appropriate bath gas x and computing the value of β_x corresponding to the experimental value¹⁷. A compilation¹³ gives details for many of the reactions considered here.

From the β_x values (most of which are for N_2 , i.e., β_{N_2}), we compute $\langle \Delta E \rangle_x$ according to the above equation. Values of $\langle \Delta E \rangle_{N_2}$ of approximately 0.3–1 kcal mole⁻¹ are generally expected. If multiple data exist, we average the values of $\langle \Delta E \rangle_{N_2}$ and recommend a rate constant corresponding to the β_{N_2} computed in the equation above.

Master equation calculations allow direct calculation of low pressure rate constants and of β_x .

Where no data exist we have sometimes estimated the low-pressure rate constant by taking $\beta_{N_2} = 0.3$ at $T = 300$ K, a value based on those cases where data exist.

2.3 Temperature Dependence of Low-Pressure Limiting Rate Constants: T^n

The value of n recommended here comes from measurements or, in some cases, a calculation of $\langle \Delta E \rangle_{N_2}$ from the data at 300 K, and a computation of $\beta_{N_2}(200 \text{ K})$ assuming that $\langle \Delta E \rangle_{N_2}$ is independent of temperature in this range. This $\beta_{N_2}(200 \text{ K})$ value is combined with the computed value of $k_{o,sc}(200 \text{ K})$ to give the expected value of the actual rate constant at 200 K. This latter, in combination with the value at 300 K, yields the value of n .

This procedure can be directly compared with measured values of k_o (200 K) when those exist. Unfortunately, very few values at 200 K are available. There are often temperature-dependent studies, but some ambiguity exists when one attempts to extrapolate these down to 200 K. If data are to be extrapolated beyond the measured temperature range, a choice must be made as to the functional form of the temperature dependence.

There are two general ways of expressing the temperature dependence of rate constants. Either the Arrhenius expression

$$k_o(T) = A \exp(-E/RT)$$

or the form

$$k_o(T) = A' T^{-n}$$

is employed. Neither of these extrapolation techniques is soundly based, and since they often yield values that differ substantially, we have used the power law expression above as the basis of our recommendations.

2.4 High-Pressure-Limit Rate Constants, $k_\infty(T)$

High-pressure rate constants can often be obtained experimentally, but those for the relatively small species of atmospheric importance usually reach the high-pressure limit at inaccessibly high pressures. This leaves two sources of these numbers, the first being estimates based upon theory, and the second being extrapolation of fall-off data up to higher pressures.

Stratospheric conditions generally render reactions of interest much closer to the low-pressure limit and thus are fairly insensitive to the high-pressure value. This means that while the extrapolation is long, and the value of $k_\infty(T)$ is often not very accurate, a “reasonable guess” of $k_\infty(T)$ will then suffice. In a few cases we have declined to guess since the low-pressure limit is effective over the entire range of stratospheric conditions.

2.5 Temperature Dependence of High-Pressure-Limiting Rate Constants: T^m

There are very few data upon which to base a recommendation for values of m . Values in Table 2 are often estimated, based on models for the transition state of bond-association reactions and whatever data are available. In general the temperature dependence of these rate constants is expected to be small.

2.6 Uncertainty Estimates

For three-body reactions (Table 2) uncertainties are assigned using a procedure that is analogous to that employed for bimolecular reactions in Table 1-1. Values of $f(298\text{ K})$ are given for these rate constants at room temperature and assumed to be valid at all pressures. The additional uncertainty arising from the temperature extrapolation is expressed with a g -factor as in Table 1-1. Given that uncertainties for an expression with four parameters are expressed with only two parameters, a certain amount of arbitrariness is involved in their choice. In general we have tried to have the “two sigma” range incorporate most of the data.

Table 2-1. Rate Constants for Termolecular Reactions

Reaction	Low-Pressure Limit ^a $k_0(T) = k_0^{300} (T/300)^{-n}$		High-Pressure Limit ^b $k_\infty(T) = k_\infty^{300} (T/300)^{-m}$		f(298 K)	g	Note

Shaded areas indicate changes or additions since JPL 10-6.

The values quoted are suitable for air as the third body, M.

^a Units are $\text{cm}^6 \text{ molecule}^{-2} \text{ s}^{-1}$.

^b Units are $\text{cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$.

f(298 K) is the uncertainty factor at 298 K. To calculate the uncertainty at other temperatures, use the expression:

$$f(T) = f(298) \exp \left[g \left(\frac{1}{T} - \frac{1}{298} \right) \right]$$

Note that the exponent is an absolute value

2.7 Notes to Table 2-1

JPL Publication numbers for the most recent revision of the table entry, note and evaluation date are given at the end of each note.

A1. O + O₂. Low pressure limit and T dependence are an average of Klais et al.,¹⁰ Huie et al.,⁷ and Lin and Leu.¹¹ These studies in N₂ and Ar are in the temperature range 200 < T/K < 268. The result is in agreement with the study of Hippler et al.⁶ and the extrapolated recommendation fits their lower pressure N₂ data down to 100 K. High pressure studies by Croce de Cobos and Troe² are in agreement with this recommendation. Rawlins et al.¹⁴ estimate values in Ar between 80 and 150 K from nascent vibrational distributions that are a factor of two higher than the recommendation extrapolated to 80 K. The temperature dependence of the rate constant determined from the experimental data are in excellent agreement with the value of n = 2.36 determined from the calculations of Patrick and Golden.¹³ However there is some reason to believe that a radical-complex plays a role in this process.^{6,8,12,19} Kaye⁹ has calculated isotope effects for this reaction, using methods similar to those discussed in the Introduction of this document (see Troe¹⁷ and Patrick and Golden¹³). Isotope effects have been reported by Anderson et al.¹ and Gross and Billing.⁴ Measurements of isotopic fractionation by Mauersberger and colleagues¹⁸ and Thiemens and co-workers¹⁵ reveal distinctly non-statistical effects. Various attempts at theoretical explanations exist,⁵ but the detailed knowledge of the potential energy surface required is unavailable. A summary of theoretical and experimental studies by Schinke et al.¹⁶ goes into great detail on this subject as does a study by Gao and Marcus.³

- A2. O(¹D) + N₂.** Recommended parameters (including f and g) are from Estupiñán et al.¹ whose detection capabilities were more advanced than those employed in earlier studies. Kajimoto and Cvetanovic³ report a value at 296 K of $6.5 \times 10^{-37} \text{ cm}^6 \text{ s}^{-1}$. Maric and Burrows⁴ extract $(8.8 \pm 3.3) \times 10^{-37} \text{ cm}^6 \text{ s}^{-1}$ from a study of the photolysis of synthetic air. Gaedtke et al.² report an approximate value of 10^{12} in molar units, which translates to 2.8×10^{-36} in molecular units. The rate constant is extremely low in this special system due to electronic curve crossing.

- B1. H + O₂.** Studies by Kurylo,⁸ Wong and Davis,¹³ Hsu et al.,⁷ Hsu et al.,⁶ Cobos et al.,⁴ Pirraglia et al.,¹⁰ Carleton et al.,³ Troe,¹² Bates et al.,¹ Michael et al.,⁹ and Fernandes et al.⁵ have been considered. All are in good agreement. A theoretical study by Sellevåg et al.¹¹ improves the knowledge of the high pressure limit and verifies the low pressure limit. The parameters in Sellevåg et al.¹¹ are the basis for the recommendation. Several studies^{1,9} have pointed out the large effect of water vapor as the collider gas. Baulch et al.² have evaluated this reaction over the temperature range 298 < T/K < 1500.

- B2. OH + OH.** Recommended values are from fits of measurements by Zellner et al.⁶ in N₂, by Forster et al.² and Fulle et al.³ in 1–150 bar He scaled to N₂. A study by Fagerstrom et al.¹ in 85–1000 mbar SF₆ gives slightly different values. A pressure independent bimolecular channel to $\text{H}_2\text{O} + \text{O}$ with a rate 1.8×10^{-12} is observed (see Table 1-1). Zellner et al. used somewhat different values for this rate constant to make substantial corrections to their measured values. Changing to the accepted value will make large changes in the Zellner et al. values and it is unclear how to evaluate this. Trainor and von Rosenberg⁵ report a value at 300 K that is lower than recommended by a factor of 2.7. A theoretical study by Sellevåg et al.⁴ recommends values for He that are compatible with the recommendation. (Table: 02-25, Note: 10-6, Evaluated: 10-6) [Back to Table](#)

Experimental and theoretical study of the temperature and pressure dependences of the recombination reactions $\text{O} + \text{NO}_2(+\text{M}) \rightarrow \text{NO}_3(+\text{M})$ and $\text{NO}_2 + \text{NO}_3(+\text{M}) \rightarrow \text{N}_2\text{O}_5(+\text{M})$. *Phys. Chem. Chem. Phys.* **2000**, *2*, 5098-5104, doi:10.1039/b005756h.
- C3. OH + NO.** The low pressure limit rate constant has been reported by Anderson and Kaufman,² Stuhl and Niki,¹⁷ Morley and Smith,¹³ Westenberg and de Haas,¹⁸ Anderson et al.,³ Howard and Evenson,¹² Harris and Wayne,¹¹ Atkinson et al.,⁶ Overend et al.,¹⁴ Anastasi and Smith,¹ Burrows et al.,⁷ and Atkinson and Smith.⁴ The general agreement is good, and the recommended values of both the rate constant and the temperature dependence are weighted averages. Studies by Sharkey et al.¹⁶ and Donahue et al.⁸ in the transition regime between low and high pressure limits are in agreement and serve to reduce the uncertainty. These latter studies yield a value for the high pressure limiting rate constant in agreement with the results of Forster et al.,⁹ whose study reached pressures of 100 bar in He. The temperature dependence of the high pressure limiting rate constant is from the data of Anastasi and Smith¹ and Sharkey et al. (both *cis*- and *trans*-HONO are expected to be formed.) Fulle et al.¹⁰ report a high pressure limit in agreement with Forster et al.⁹ Pagsberg et al.¹⁵ report low pressure values in SF₆ that are compatible (i.e., the ratio of collision efficiencies is about a factor of two) with the recommendation. A study by Zabarnick¹⁹ is noted. The error limits encompass the differences with the IUPAC⁵ recommendation.

C4. OH + NO₂. This reaction has been the subject of detailed study. There are two product channels, one to HONO₂ (nitric acid) and the other to HOONO (pernitrous acid). (There are at least two conformers of HOONO, *cis-cis* and *trans-perp*, which are thought to be equilibrated under atmospheric conditions.) Golden and Smith¹⁴ concluded that there were two pathways and they offered parameters in the format of this recommendation that were given in the note in JPL 02-25.²⁰ Experiments by Hippler and co-workers^{11,12} up to about 100 bar at 300 K and the finding of a double exponential decay of OH at 430 K and 100 bar implicate a second pathway.¹⁵ Nizkorodov and Wennberg¹⁸ report 5% HOONO at 253 K and 20 Torr of an N_2/He buffer gas. Bean et al.³ and Pollack et al.¹⁹ report on the spectroscopy of the HOONO conformer. Mollner et al.¹⁷ report the total rate constant at 298 K in N_2 , O_2 and air from 50 to 900 Torr, and the branching ratio for the two pathways at 298 K in a mixture of N_2 and H_2 from 20 to 760 Torr. They find the efficiency of air to be 94% that of N_2 and by simultaneously fitting both the branching ratio and the total rate constant they obtained parameters at 298 K: $k_0 = 1.51 \times 10^{-30}$ and $k_\infty = 1.84 \times 10^{-30}$ for the HONO₂ pathway and $k_0 = 6.2 \times 10^{-32}$ and $k_\infty = 8.1 \times 10^{-11}$ for the HOONO pathway.

Golden et al.¹³ have performed RRKM/master-equation calculations on an ab initio potential energy, which are the basis for the previous recommendation, which is retained for the current recommendation. Golden et al.¹³ adjusted their calculations to agree with experiments: the low pressure limit and the high pressure limiting rate constants and their temperature dependences are from a fit to the data of Hippler et al.,¹⁵ Anastasi and Smith,¹ Wine et al.,²¹ Donahue et al.,⁸ Dransfield et al.,⁹ Brown et al.,⁴ and D'Ottone et al.⁷ Brown et al. report that O_2 is about 30% less efficient than N_2 as a collider and suggest that air might therefore have a total efficiency of 0.94 relative to N_2 . The total rate constants reported by Mollner et al.¹⁷ are in excellent agreement with the recommendation. Data from Anderson et al.,² Howard and Evenson,¹⁶ Burrows et al.,⁶ and Erler et al.¹⁰ are in essential agreement. Data of Forster et al.¹¹ and Fulle et al.¹² are acknowledged to be about 30% too high.¹⁵ Burkholder et al.⁵ and Dransfield et al.⁹ searched for the isomer HOONO, but were unable to detect it. The description of the reaction between HO and NO_2 , as consisting of two product channels, requires that the data represent the sum of the two pathways. The branching ratios measured at 298 K by Mollner et al.¹⁷ are about 25% lower than from the recommendation; Mollner et al. did not report branching ratios at other temperatures. The fate of HOONO has to be included in atmospheric models. If this fate involves rapid loss due to reaction or photolysis, the effect of the second pathway is the diminution of the HONO₂ forming rate constant. Evaluation of data, taking into account both pathways, indicates that the contribution of the HOONO forming reaction can be from 5 to 15% under atmospheric conditions at 298 K. The equilibrium constant is given in Table 3-1.

- C5. $\text{HO}_2 + \text{NO}$.** Butkovskaya et al. studied this reaction in a high pressure turbulent flow reactor coupled to a chemical ionization mass spectrometer.²⁻⁴ Very small yields (<1%) of nitric acid were measured from 223 to 323 K and from 72 to 600 Torr of (mostly) N_2 and in the absence of water vapor. The yields were enhanced by the presence of water vapor.^{3,4} In systems not including water vapor, they summarized the yield of nitric acid relative to the yield of NO_2 (from $\text{HO}_2 + \text{NO} \rightarrow \text{OH} + \text{NO}_2$) as follows:

$$\beta(T, P) = (530 \pm 10)/T(K) + (6.4 \pm 1.3) \times 10^{-4} P(\text{Torr}) - (1.73 \pm 0.07).$$

At low temperatures, β extrapolated below 100 Torr has a large non-zero intercept at zero pressure,^{2,4} which is not expected for a gas phase reaction. In the presence of water vapor, the chemical ionization mass spectrometer signals are affected significantly³ and the yield of nitric acid increases linearly with added water vapor,^{3,4} reaching an enhancement factor of ~ 8 at $[\text{H}_2\text{O}] = 4 \times 10^{17} \text{ molecule cm}^{-3}$ and 298 K³:

$$f_{\text{H}_2\text{O}} \approx (1 + 2 \times 10^{-17} [\text{H}_2\text{O}])$$

where the concentration of H_2O is expressed in molecules cm^{-3} . If this effect is due to reaction of the hydrated HO_2 complex (i.e. $\text{HO}_2 \cdot \text{H}_2\text{O} + \text{NO} \rightarrow \text{HNO}_3 + \text{H}_2\text{O}$), then the rate constant of the complex with NO is $\sim 6 \times 10^{-13} \text{ cm}^3 \text{ s}^{-1}$ at 298 K in the presence of 200 Torr of N_2 .³

Ab initio electronic structure calculations support the possibility of gas phase HONO_2 formation, but satisfactory simulations using master equations have been elusive.^{1,5-7} The measured yields show a surprising intercept at zero pressure, which might be indicative of wall reactions. However, Butkovskaya et al. have made great efforts to minimize wall reactions, and their analysis suggests that wall reactions should not be important.^{3,4} Until the results have been confirmed by other groups and are better understood, no recommendation can be made. These rate parameters are provided for the purposes of model evaluation only and do not constitute a recommendation by the Panel.

C6. $\text{HO}_2 + \text{NO}_2$. Christensen et al.² report rate constants $219 < T/\text{K} < 298$ and $45 < P/\text{Torr} < 200$. They show that methanol, present in most other studies confounds the results by forming bound complexes with HO_2 . They also suggest that some measurements yielded low rate constants as a result of perturbations to the $\text{NO}_2/\text{N}_2\text{O}_4$ equilibrium. Sander et al.⁸ also noted that H_2O vapor enhances the reaction rate significantly. Bacak et al.¹ reported data obtained using CIMS, which is more sensitive and less prone to interference than UV and IR absorbance. They used initial radical concentrations 1000 times lower than previous work, eliminating potential interference from the $\text{HO}_2 + \text{HO}_2$ reaction. Rate constants measured by Bacak et al.¹ at 200 K, 223 K, and 298 K are quite similar to each other, suggesting very little temperature dependence (i.e., Bacak gives $n = 0.2$ and $m = 0.5$), which differs from previous work, leading them to conclude that previous work was affected by the $\text{HO}_2 + \text{HO}_2$ reaction at $T < 277$ K. At ~ 298 K, rate constants measured by Sander et al.,⁸ Kurylo et al.,^{6,7} Christensen et al., and Bacak et al. are in excellent agreement, suggesting that at 298 K these studies were not affected by interferences. The recommendation is based on the data at $T \geq 277$ K from Sander and Peterson,⁸ Kurylo and Ouellette,^{6,7} Christensen et al.,² and the data at 298 K of Bacak et al. The recommended parameters are similar to the previous recommendation; the exponent for k_∞ is small, as expected for a recombination reaction. The low-T data of Bacak et al. fall about a factor of two lower than the fit. Although CIMS experiments have the highest sensitivity and avoid spectral interference, the data are limited to only three temperatures and they have not been replicated at the lowest two temperatures. The error parameter g was chosen so that the CIMS data at low T fall within the error range. Other studies by Howard,⁵ Simonaitis and Heicklen,⁹ and Cox and Patrick⁴ are in reasonable agreement with the recommendation, as is the value of Christensen et al.³ (Table: 15-10, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

C7. NO₂ + NO₃. The recommended limiting rate constants at 298 K (N₂ bath gas) and temperature exponents are the geometric mean of the corresponding rate constants and the average of the exponents, respectively, obtained by nonlinear least squares. The low pressure limit is based on the data of Kircher et al.,⁹ Smith et al.,¹² Wallington et al.,¹⁴ Orlando et al.,¹¹ and Nakano et al.,¹⁰ combined with $k_{\text{uni}} \times K_{\text{eq}}$ data (recommended K_{eq} from Table 3-1); k_{uni} data were taken from Connell et al.³ and Cantrell et al.² The high pressure limit is based on data from Kircher et al.,⁹ Smith et al.,¹² Wallington et al.,¹⁴ Hahn et al.,⁶ and $k_{\text{uni}} \times K_{\text{eq}}$ (K_{eq} from Table 3-1); k_{uni} data were taken from Cantrell et al.² and Ide et al.⁷ The recommendation is in good agreement with the data of Burrows et al.¹ and with k_{uni} (multiplied by K_{eq} from Table 3-1) reported by Viggiano et al.¹³ Values from Croce de Cobos et al.⁴ were excluded due to arguments given by Orlando et al.,¹¹ who point out that a reanalysis of these data using better values for the rate constant for NO₃ + NO → 2NO₂ yields a negative value for NO₂ + NO₃ + M. The study of Fowles et al.⁵ is noted, but not used. Johnston et al.⁸ reviewed this reaction. The rate constant for the reverse reaction (k_{uni}) can be obtained as the ratio of the recommended recombination rate constant k_{rec} from this table, divided by the recommended K_{eq} from Table 3-1:

$$k_{\text{uni}} = k_{\text{rec}}/K_{\text{eq}}$$

C8. NO₃ + M. Johnston et al.³ and Davidson et al.¹ have suggested significant thermal decomposition of NO₃. This has been disputed by Russell et al.⁴ Davis et al.² claim that the barrier to thermal dissociation is 47.3 kcal mol⁻¹. This would seem to rule out such a process in the atmosphere.

D1. HO + CO. This recommendation takes into account the fact that the reaction proceeds via initial formation of a chemically activated HOCO* intermediate, which can re-dissociate to HO + CO, dissociate to H + CO₂, and be collisionally stabilized to yield thermalized HOCO. In the presence of O₂, the H + CO₂ product set and the HOCO intermediate are both converted to HO₂ + CO₂ (DeMore⁶, Miyoshi et al.¹⁴). Miyoshi et al. report a rate constant for the reaction HOCO + O₂ → HO₂ + CO₂ of $\sim 1.5 \times 10^{-12} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ at 298 K (recommended Arrhenius parameters are given in Table 1-1). Therefore, for atmospheric purposes, the products can be taken to be HO₂ and CO₂. The recommended parameters are based on data from McCabe et al.¹³ and Liu and Sander,¹² because these two comprehensive studies extended to much lower temperatures than the others. The parameters were obtained by assuming the k_∞ parameters are the same as the previous recommendation and that the relative errors are constant, and then carrying out least squares fits; the results from the two data sets were averaged. Pressure and temperature dependent data from McCabe et al.,¹³ Hynes et al.,¹⁰ and Liu and Sander¹² are well represented by the recommended parameters. This reaction has been studied by many workers. In general the results are in keeping with the current recommendation. Values have been reported by Dreier and Wolfrum,⁷ Husain et al.,⁹ Ravishankara and Thompson,²¹ Paraskevopoulos and Irwin,¹⁹ Hofzumahaus and Stuhl.⁸ The results of Jonah et al.¹¹ are too high and were not included. An increase in k with pressure has been observed by a large number of investigators: Overend and Paraskevopoulos,¹⁷ Perry et al.,²⁰ Chan et al.,⁴ Biermann et al.,² Cox et al.,⁵ Butler et al.,³ Paraskevop and Irwin,^{18,19} DeMore,⁶ Hofzumahaus and Stuhl,⁸ Hynes et al.,¹⁰ McCabe et al.,¹³ and Liu and Sander.¹² In addition, Niki et al.¹⁶ have measured k relative to OH + C₂H₄ in one atmosphere of air by following CO₂ production using FTIR. Previous controversy regarding the effect of small amounts of O₂ (Biermann et al.²) has been resolved and is attributed to secondary reactions (DeMore,⁶ Hofzumahaus and Stuhl⁸). Liu and Sander¹² has demonstrated that modest levels of O₂ do not interfere with measuring the total rate constant. Currently, there are no indications to suggest that the presence of O₂ has any effect on the rate coefficient other than as a third body. The results of Butler et al.³ have to be re-evaluated in the light of refinements in the rate coefficient for the OH + H₂O₂ reaction; the corrected rate coefficient is in approximate agreement with the recommended value. Beno et al.¹ observe an enhancement of k with water vapor, which is in conflict with the flash photolysis studies; e.g., Ravishankara and Thompson,²¹ Paraskevopoulos and Irwin,¹⁹ Hynes et al.,¹⁰ and McCabe et al.¹³ Water is not expected to significantly change the rate coefficient for the reaction in the atmosphere and it is not expected to alter the products of the reaction. Troe²³ has carried out extensive theoretical analysis of this reaction system. Senosiain et al.²² performed empirical master equation calculations on a theoretical potential energy surface. (The value of the exponent of k_∞ for the chemical activation pathway has a sign error in the reference.) The recent fully *ab initio* calculations of Nguyen et al.¹⁵ (also Weston et al.²⁴) fitted from 175–300 K predict $k_\infty(300) = 7.4 \times 10^{-13} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$, $n = -1.50$ (which can be compared with the first line of entries for this reaction in Table 2), and $k_{\text{bim}}(300) = 1.4 \times 10^{-13} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$, $n_{\text{bim}} = -0.44$ (which can be compared with the first two entries on the second line); all of these parameters are in very good agreement with the recommended values.

Important: For practical applications in Earth's atmosphere, the total rate constant is well-represented as the sum of a bimolecular reaction and a termolecular reaction. To calculate rate constants for the termolecular reaction (i.e. OH +

CO $\xrightarrow{\text{M}}$ HOCO), use the standard expression for termolecular reactions, $k_t([M], T)$, given in the Introduction (Section 2.1), and the data on the first line of the entry for this reaction in Table 2. To calculate rate constants $k_{\text{bim}}(T)$ for the bimolecular reaction (i.e. OH + CO → H + CO₂), use $k_{\text{bim}}(T) = k_0(300) \times (T/300)^{-n}$ with parameters taken from the second line in the table entry. For rate constants and branching ratios that are more accurate, use $k_t([M], T)$ together with the expression for chemical activation reactions, $k_f^{\text{ca}}([M], T)$, given in the Introduction (Section 2.1).

D2. $\text{CH}_3 + \text{O}_2$. Data from Kaiser⁵ are fit to the NASA format. The ranges of this study were $3 < P/\text{Torr} < 11000$ and $264 < T/\text{K} < 370$. The rate constant was measured relative to the reaction $\text{CH}_3 + \text{Cl}_2 \rightarrow \text{CH}_3\text{Cl} + \text{Cl}$, $\text{k}/\text{cm}^3 \text{ molecule}^{-1} \text{ s}^{-1} = 1.61 \times 10^{-12} \exp(-530/RT)$. The recommended values are in good agreement with those from Selzer and Bayes.¹² These workers determined the rate constants as a function of pressure in N_2 , Ar , O_2 , and He . Plumb and Ryan¹⁰ report a value in He which is consistent within error limits with the work of Selzer and Bayes. Pilling and Smith⁹ have measured this process in Ar (32–490 Torr). Cobos et al.² have made measurements in Ar and N_2 from 0.25 to 150 atmospheres. They report parameters somewhat different than recommended here. The work of Laguna and Baughcum⁷ seems to be in the fall-off region. Results of Pratt and Wood¹¹ in Ar are consistent with this recommendation, although the measurements are indirect. The suggested value accommodates the values of Keiffer et al.,⁶ who measured the process in Ar between 20 and 600 Torr and in the range $334 < T/\text{K} < 582$. Data of van den Bergh and Callear,¹³ Hohanadel et al.,⁴ Basco et al.,¹ Washida and Bayes,¹⁵ Laufer and Bass,⁸ and Washida¹⁴ are also considered. A theoretical study by Zhu et al.¹⁶ is in reasonable agreement with the recommendation. A study by Fernandes et al.³ at pressures from 2–1000 bar and temperatures between 300 and 700 K presents a parameterization of the rate constant as a function of pressure and temperature which is in agreement with this recommendation at 300 K. If their parameters are used at 200 K the agreement is not as good, but is within the 95% uncertainty limit. (Table: 06-2, Note: 10-6, Evaluated: 10-6) [Back to Table](#)

D3. $\text{C}_2\text{H}_5 + \text{O}_2$. Kaiser et al.² extract from a relative rate study: $k_\infty = (9.2 \pm 0.9) \times 10^{-12} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ and $k_0 = (6.5 \pm 2.0) \times 10^{-29} \text{ cm}^6 \text{ molecule}^{-2} \text{ s}^{-1}$ in He at 298 K and pressures between 3 and 1500 Torr. k_∞ has been calculated by Wagner et al.,⁶ Miller and Klippenstein,³ and Sheng et al.⁵ with $k_\infty(300 \text{ K}) = 8, 10$, and $4 \times 10^{-12} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$, respectively. Although all cite some small temperature dependence, the values are stated to hold above 300 K. The Kaiser et al.,² extrapolation to the low-pressure limit is difficult due to the complex potential energy surface, but agrees with a Patrick and Golden-type calculation⁴ using $\Delta H_0^0 = 32.4 \text{ kcal mol}^{-1}$. The recommended values use the calculated temperature dependence and a 2.5 times higher rate constant for air as the bath gas, in line with suggestions in Kaiser et al.¹

D4. $\text{OH} + \text{C}_2\text{H}_2$. The rate constant for this complex process has been examined by Smith et al.¹³ in the temperature range from 228 to 1400 K, and in the pressure range 1 to 760 Torr. Their analysis, which is cast in similar terms to those used here, is the source of the rate constants and temperature dependences at both limits. The negative value of m reflects the fact that their analysis includes a 1.2 kcal/mol barrier for the addition of OH to C_2H_2 . The data analyzed include those of Pastrana and Carr,¹ Perry et al.,¹⁰ Michael et al.,⁸ and Perry and Williamson.¹¹ Other data of Wilson and Westenberg,¹⁶ Breen and Glass,³ Smith and Zellner,¹⁴ and Davis et al.⁴ were not included. Studies by Liu et al.⁷ and Lai et al.⁶ are in general agreement with the recommendation. Calculations of k_0 via the methods of Patrick and

Golden⁹ yield values compatible with those of Smith et al.¹³ A study by Sørensen et al.¹⁵ at 298 K and pressures from 25 to 8000 Torr of bath gas suggests $k_0/\text{cm}^6 \text{ molecule}^{-2} \text{ s}^{-1} = 2.92 \times 10^{-30}$, $k_\infty/\text{cm}^3 \text{ molecule}^{-1} \text{ s}^{-1} = 9.69 \times 10^{-13}$ and $F_c = 0.6$. No difference was found between air, N₂/O₂ mixtures or O₂ as the bath gas. These values yield rate constants as a function of pressure at 298 K in agreement with this recommendation, so the recommended values are unchanged from JPL 02-25. Earlier, Fulle et al.⁵ reported a high pressure limiting rate constant of $2 \times 10^{-12} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$, which is the basis for the IUPAC² recommendation. A theoretical study by Senosiain et al.¹² is in essential agreement with this recommendation.

D5. OH + C₂H₄. The recommendation for the low pressure limit at 300 K is the average of fitted values from studies carried out over a significant range of pressure using synthetic air (Klein et al.⁹), N₂ (Vakhtin et al.¹⁷ and Cleary et al.²), or Argon (Klein et al.⁹). All three colliders were treated as equivalent. The recommended temperature exponent (n) was taken from the master equation analysis by Golden,⁶ who fitted the experimental rate constants in N₂, including those at very low temperatures (96, 110, and 165 K) reported by Vakhtin et al.¹⁷ The recommendation for the high pressure limit at 300 K is the average of fitted values from eight data sets measured near 300 K using helium (Tully et al.,¹⁶ Kuo and Lee,¹⁰ and Cleary et al.²), argon (Klein et al.⁹), N₂ (Vakhtin et al.¹⁷ and Cleary et al.²), and synthetic air (Klein et al.⁹). The recommended temperature exponent was from a least squares fit of the high pressure limiting values obtained from individual fits of data at 15 temperatures ranging from 200 K to 430 K, including data near 300 K.^{2,9,10,16,17} In addition to the studies already mentioned, the recommended high pressure rate constants are in good agreement with the data of Davis et al.,⁴ Howard,⁸ Greiner,⁷ Morris et al.,¹² and Overend and Paraskevopoulos¹³ in helium, Atkinson et al.¹ in argon, and Lloyd et al.¹¹ and Cox³ in nitrogen/oxygen mixtures. The parameters recommended are similar to the curve proposed by Klein et al.⁹ at 298 K. Kuo and Lee¹⁰ report a stronger temperature dependence for the low-pressure limit (n=4), but the present recommendation is in good agreement with their

measured rate constants. Calculations of the type in Patrick and Golden¹⁴ as described in Vakhtin et al.¹⁷ yield $n = 4.2$, although they use a somewhat low value for energy transfer by nitrogen. The high-pressure limit temperature dependence has been determined by several workers. Zellner and Lorenz¹⁸ report a value equivalent to $m = +0.8$ over the range ($296 < T/K < 524$) at about 1 atmosphere. A value of $m = +2.0$ fits the data ($540 < T/K < 670$) of Diau and Lee.⁵ Cleary et al.² report values in N_2 at 295 K. They also report values in He between 200 and 400 K. They perform master equation calculations and report fitting parameters. Taylor et al.¹⁵ report data at a single pressure and 69 and 86 K. Their data are well-accommodated by this recommendation and by the parameters in Cleary et al.² (Table: 15-10, Note: 15-10, Evaluated: 15-10) [Back to Table](#)

D6. OH + CH₃CH=CH₂ (propene). The following studies have been used to reach the recommendation: Spangenberg et al.¹⁰ in a Laval nozzle expansion of N₂ with LIF detection of OH at 293 K and at individual points from 114 to 58 K; Vakhtin et al.^{12,13} in a Laval nozzle expansion of N₂ with LIF detection of OH at 296 K and individual points at 96, 110, and 165 K; Nielsen et al.⁶ in a pulse radiolysis experiment (kinetic UV absorbance of OH radical) at 298 K in 1 atm of air; Wallington¹⁴ in a pulsed laser photolysis experiment with LIF detection of OH at 298 K in Argon; Schmidt et al.⁹ with laser photolysis and LIF of OH at 295 K in 1 atm of air; Tully and Goldsmith¹¹ with laser photolysis and LIF detection of OH at 293 to 467 K in 25 to 600 Torr of He; Zellner and Lorenz¹⁵ laser photolysis and resonance fluorescence detection of OH at 297 K in 1.3–130 mbar of Ar; Klein et al.⁴ with a relative rate measurement (relevant to n-Hexane) at 295 K in 1.3–1000 mbar of air; Atkinson and Aschmann¹ from relative rate measurements at 295 K in

1 atm of air; Nip and Paraskevopoulos⁷ with flash photolysis and resonance absorption at 297 K in 75 mbar of an H₂/N₂O mixture; Ravishankara et al.⁸ with flash photolysis and resonance fluorescence of OH at 295 K in 20 and 200 Torr of He; and Atkinson and Pitts² by flash photolysis and resonance fluorescence of OH at 298–425 K in 25–100 Torr of Ar. Additional studies have been reviewed by Calvert et al.³ The recommended high pressure rate constant at 298 K is the geometric mean of all of the studies listed above, except for the relative rate measurement of Klein et al.⁴ The temperature exponent of k_{∞} (parameter m) is the average of the values obtained from weighted least squares fits of data from Tully and Goldsmith¹¹ and from Vakhtin et al.;¹³ the former extends upward from ~300 K and the latter extends downward. Pressure fall-off is only apparent at lower pressures and higher temperatures; most studies did not observe significant fall-off. Usable fall-off data near 300 K are available from Klein et al.⁴ (Ar bath gas), Zellner and Lorenz¹⁵ (Ar bath gas), and Vakhtin et al.¹³ (N₂ bath gas). These fall-off data sets are for two different collider gases and provide only rough estimates of $k_0(298)$; the error factor associated with k_0 is at least $\times 3$. Because no temperature-dependent fall-off data are available, the recommendation for the temperature exponent (parameter n) is based on the estimate by Calvert et al.³ Loison et al.,⁵ using a fast flow reactor coupled to a time of flight mass spectrometer, found that $71 \pm 16\%$ of the reaction near room temperature proceeds by addition of the OH to the terminal CH₂ group.

D7. OH + CH₂=C(CH₃)CH₃ (iso-butene). The rate constant is not dependent on pressure even at 1 Torr of helium, suggesting that it is very near the high pressure limit in all of the reported studies. The recommended high pressure rate constant at 298 K is the geometric mean of the absolute rate constants reported by Atkinson and Pitts (flash photolysis (FP) with resonance fluorescence (RF) detection of OH)² and relative rate measurements reported by Wu et al.⁸ (cited by Calvert et al.⁴), Barnes et al.,³ Ohta,⁶ and Atkinson and Aschmann.¹ The recommendation is in fair agreement with the early discharge-flow measurement of Morris and Niki.⁵ The temperature dependence is based on

the measurements of Atkinson and Pitts.² The estimated 2 σ error limits are set to include all of the data used in the recommendation; because there is only one study of temperature dependence, f(298) and g were set to 1.2 and 200, respectively. Calvert et al.⁴ reviewed the data published prior to 2000 and recommended rate constants in reasonable agreement with the present recommendation. The reaction proceeds mostly (>90%) by addition of OH to the two carbon atoms at the ends of the double bond.⁴ Peeters et al.⁷ reported that 85 $\pm$ 10% of the addition is to the terminal carbon atom, producing a tertiary free radical (the balance produces a primary free radical).

D8. OH + CH₂=CH₂CH₂CH₃ (1-butene). The rate constant is not dependent on pressure even at 1 Torr of helium, suggesting that it is very near the high pressure limit in all of the studies. The recommended high pressure rate constant at 298 K is the geometric mean of the absolute rate constants reported by Atkinson and Pitts² (flash photolysis (FP) with resonance fluorescence (RF) detection of OH), Ravishankara et al.¹³ (FP-RF), Nip and Paraskevopoulos⁹ (FP with resonance absorption (RA) detection of OH), Biermann and Pitts⁴ (discharge flow (DF) with mass spectrometry (MS) detection), Sims et al.¹⁴ (Laval-Nozzle flow apparatus (LN) and laser induced fluorescence (LIF) detection of OH), Vakhtin et al.¹⁵ (LN-LIF), and relative rate measurements reported by Wu et al.¹⁷ (cited by Calvert et al.⁵), Lloyd et al.,⁶ Winer et al.,¹⁶ Barnes et al.,³ Ohta,¹⁰ and Atkinson and Aschmann.¹ The recommendation is in good agreement with the early discharge-flow measurement of Morris and Niki,⁸ and in poor agreement with that of Pastrana and Carr,¹¹ which possibly was affected by secondary reactions. The temperature dependence is based on the measurements of Atkinson and Pitts,² Sims et al.,¹⁴ and Vathkin et al.¹⁵ Calvert et al. reviewed the data published prior to 2000 and recommended rate constants⁵ in good agreement with the present recommendation. The estimated 2 σ error limits are set to include all of the data used in the recommendation. The reaction proceeds mostly (>90%) by addition of OH to the two carbon atoms at the ends of the double bond.⁵ Peeters et al.¹² measured product branching ratios in a multi-stage flow apparatus with mass spectrometric detection and concluded that 85 $\pm$ 10% of the OH addition reaction proceeds by addition to the terminal CH₂ group, producing a secondary free radical. Peeters et al. also developed a structure-activity relationship (SAR) for predicting the product distribution for OH + alkene reactions. Loison et al.⁷ also used a flow apparatus with mass spectrometric detection, but with photoionization, and reported that 71 $\pm$ 16% of the addition reaction is to the terminal CH₂ group, in good agreement with Peeters et al. Furthermore, Loison et al. concluded that 8 $\pm$ 3% of the total reaction is due to abstraction.

D11. CH₃O + NO. This reaction proceeds via a complex potential energy surface that includes both chemical activation and direct abstraction routes¹ to the disproportionation products CH₂O and HNO as well as the combination to form CH₃NO. The chemical activation process would have inverse pressure dependence and the direct abstraction would be pressure independent. The recommended values take into account the results of Frost and Smith⁴ in Ar and CF₄ and of Caralp et al.¹ in He and Ar. In both of these references the disproportionation process is subtracted from total loss of CH₃O with a pressure independent, temperature dependent value. At 300 K below one Torr the disproportionation process dominates. Temperature dependences are from the higher temperature results. The low pressure rate constant is consistent with the measurements of McCaulley et al.⁵ and Daële et al.² in helium. Studies by Ohmori et al.⁶ and Dobé et al.³ are in general agreement with respect to both the addition and bimolecular pathways. (See the note in Table 1-1 for the bimolecular pathway.)

D12. $\text{CH}_3\text{O} + \text{NO}_2$. The recommended values are from the work mostly of Wollenhaupt and Crowley (in Ar).⁶ Agreement is good with earlier work at 298 K from the study of Frost and Smith² in Ar (corrected by Frost and Smith³) and that of Biggs et al.¹ and Martinez et al.⁴ in He. Low pressure results agree within a factor of two with the measurements of McCaulley et al.⁵ in He. A minor bimolecular (chemical activation) pathway is also observed. (See Table 1-1.)

Kinetic studies of the reactions $\text{CH}_3 + \text{NO}_2 \rightarrow \text{products}$, $\text{CH}_3\text{O} + \text{NO}_2 \rightarrow \text{products}$, and $\text{OH} + \text{CH}_3\text{C}(\text{O})\text{CH}_3 \rightarrow \text{CH}_3\text{C}(\text{O})\text{OH} + \text{CH}_3$, over a range of temperature and pressure. *J. Phys. Chem. A* **2000**, 104, 6429-6438, doi:10.1021/jp0005726.

D13. $\text{C}_2\text{H}_5\text{O} + \text{NO}$. High-pressure data at 298 K in Ar from Frost and Smith³ and in He between 286 and 388 K at pressures from 30 to 500 Torr, from Fitschen et al.² Low-pressure measurements in He are from Daele et al.¹ He experiments were scaled to N_2 by dividing by a factor of 2.5. Ar data were taken as equivalent to N_2 or air. The data were fit by subtracting an assumed pressure independent value of 1×10^{-11} from the measured rate constants to account for the route to form HNO and CH_3CHO . The low pressure value agrees with theory. The bimolecular channel with an estimated rate constant of about 10^{-11} needs to be verified by direct studies. The temperature dependence of the low pressure limit is estimated and that of the high pressure limit is taken from Fitschen et al.² (The high pressure rate expression in Fitschen et al. seems to be in error.)

- (1) Frost, M. J.; Smith, I. W. M. Rate constants for the reactions of CH_3O and $\text{C}_2\text{H}_5\text{O}$ with NO_2 over a range of temperature and total pressure. *J. Chem. Soc. Faraday Trans.* **1990**, 86, 1751-1756.

D15. $\text{CH}_3\text{O}_2 + \text{NO}_2$. Golden³ has re-evaluated the data for this reaction. The recommended parameters are from a fit to Percival⁴ and temperature- and pressure-dependent data in Sander and Watson⁶ and Ravishankara et al.⁵ The temperature dependence of the high pressure rate constant is a little high, but results from the statistical fit to the data. The values recommended herein, were taken with the data in a study of the reverse reaction by Zabel et al.⁷ to compute the value of the equilibrium constant in Table 3-1. Destriau and Troe² have fit the above data with k_∞ independent of temperature and $F_c = 0.36$. Bridier et al.¹ are in good agreement with this recommendation at one atmosphere and 298 K.

D16. $\text{C}_2\text{H}_5\text{O}_2 + \text{NO}_2$. The only experimental study is that of Elfers et al.³ who measured the rate constant relative to the $\text{C}_2\text{H}_5\text{O}_2 + \text{NO}$ reaction between 10 and 1000 mbar. Elfers et al. used a value of $k = 8.9 \times 10^{-12} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ for the reference reaction. By comparison the recommended rate constant for the reference reaction from Table 1-1 of this evaluation is $1.1 \times 10^{-11} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ at 254 K. There are three data points. An evaluation of the Elfers et al. work by Destriau and Troe² cast the data in the format used in the IUPAC evaluation.¹ The parameters in Table 2 are adjusted to agree with the data corrected for the change in the reference reaction, using the simpler formula employed in this recommendation.

D17. $\text{CH}_3\text{C}(\text{O})\text{O}_2 + \text{NO}_2$. The recommended parameters are from the data of Bridier et al.,¹ who report in the format represented here, but using $F_c = 0.3$. Their values are: $k_0^{300} = (2.7 \pm 1.5) \times 10^{-28}$, $k_\infty^{300} = (12.1 \pm 2.0) \times 10^{-12}$, with $n = 7.1 \pm 1.7$ and $m = 0.9 \pm 0.15$. Studies of the decomposition of $\text{CH}_3\text{C}(\text{O})\text{O}_2\text{NO}_2$ [PAN] by Roberts and Bertman,⁴ Grosjean et al.,² and Orlando et al.³ are in accord with those of Bridier et al.¹ In the Roberts and Bertman⁴ study it was shown that PAN decomposition yields only peroxyacetyl radical and NO_2 ; no methyl nitrate. Studies by Seefeld et al.⁵ and Sehested et al.⁶ of the relative rates of $\text{CH}_3\text{C}(\text{O})\text{O}_2$ with NO and NO_2 are confirmatory. A study by von Ahsen et al.⁷ involving matrix isolation of the products of PAN decomposition, suggests a minor pathway due to O-O bond fission.

D18. CH₃CH₂C(O)O₂ + NO₂. This reaction, forming peroxypropionyl nitrate (PPN), has been studied in the reverse direction by Schurath and Wipprecht,⁴ Mineshos and Glavas,³ Grosjean et al.,¹ and Kirchner et al.² Group additivity considerations indicate that the equilibrium constant for both PAN and PPN will be the same (both sides of the equilibrium for PPN differ from those for PAN by the group C-(C)(CO)(H)₂). Therefore, the recommended value for the association reaction is taken from the decomposition studies multiplied by the same equilibrium constant as for PAN. The resulting values are very similar to those for CH₃C(O)O₂ + NO₂ forming peroxyacetyl nitrate (PAN). Conservative error limits are estimated.

D19. CH₃C(O)CH₂ + O₂. Cox et al.¹ reported a value of $k = (1.5 \pm 0.3) \times 10^{-12} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ at 298 K and 1 atm of SF₆ in which a pulse radiolysis study was modeled. Studies in He at 298 K have been reported by Oguchi et al.,⁵ Imrik et al.,³ Kovacs et al.,⁴ and Hassouna et al.² This data can be accommodated with $k_0 = 1.5 \times 10^{-29} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$, $k_\infty = 1.0 \times 10^{-12} \text{ s}^{-1}$ with $f = 1.15$. To account for the difference between He and N₂, $k_0 = 3 \times 10^{-29}$, and $f = 1.3$ are estimated and recommended. Hassouna et al. report rate constants in the temperature range 291 to 400 K at 130 and 650 bar He showing a slight negative temperature dependence. They also report data at 10 bar He in the temperature range 459 to 520 K. These latter data exhibit biexponential decays from which the equilibrium constant is also extracted. (See Table 3-1.)

D20. CH₂OO + CH₂OO (Criegee intermediate). The recommendation is the average of the rate constants reported near 298 K by Buras et al.¹ and Ting et al.⁶ (the latter supersedes the report of Su et al.⁵). The reaction does not depend on pressure at least up to 1 atmosphere, because of the existence of low energy thresholds for subsequent isomerization and fragmentation.⁷ The reaction products are thought to be 2 H₂CO + O₂(¹Δ_g). Because of the rapid reactions of CH₂OO and the complex mixtures of reactants present in the systems that have been studied, rate constants must be extracted from complicated mechanisms.^{1-4,6,7} Ting et al.⁶ have presented an analysis using perhaps the most comprehensive mechanism to date, but this field is changing very rapidly.

E1. $\text{F} + \text{O}_2$. Values are taken from a study by Campuzano-Jost et al.,² with experiments from 100 to 420 K at pressures of He, Ar and N_2 from 1 to 1000 bar. (They used $F_c = 0.54(T/300)^{-0.09}$, but the results are essentially the same with $F_c = 0.6$.) A study by Pagsberg et al.⁷ reports k_0 in argon $= 4.38 \times 10^{-33} (T/300)^{-1.2}$. There is also good agreement with earlier values of Smith and Wrigley,⁹ Smith and Wrigley,¹⁰ Shamonina and Kotov,⁸ Arutyunov et al.,¹ Wallington and Nielsen,¹² Wallington et al.,¹¹ and Ellerman et al.⁵ The values are slightly lower than the values of Chen et al.⁴ and Chegodaev et al.³ Lyman and Holland⁶ report a slightly lower value in Ar at 298 K. Campuzano-Jost et al.² and Pagsberg et al.⁷ also determined the equilibrium constant and thus $\Delta H_{f,298}(\text{FO}_2) = 6.13 \pm 0.5 \text{ kcal mol}^{-1}$. See $\text{F} + \text{O}_2$ in Table 3-1.

- E3. $F + NO_2$.** Fasano and Nogar³ studied this reaction in N_2 at 300 K. Pagsberg et al.⁵ studied the reaction in SF_6 and Zetzsch⁷ studied it in He. The results from Fasano and Nogar³ and Pagsberg et al.⁵ were used to determine both the high and low pressure limits at 300 K. Treatment of the data for this system requires knowledge of the relative stabilities of FNO_2 and $FONO$. Patrick and Golden⁶ assumed that the difference between these would be the same as between the $ClNO_2$ isomers. Theoretical work by Dixon and Christie,² Lee and Rice,⁴ and Amos et al.¹ indicates that FNO_2 is 35–40 kcal mol⁻¹ more stable than $FONO$, and therefore the measured rate refers to FNO_2 formation. The value of $n = 2$ is from Patrick and Golden, but consistent with Pagsberg et al.⁵ who made a few measurements at 341 K. The value of m is a rough estimate from similar reactions, but is also consistent with Pagsberg et al.⁵ (Table: 06-2, Note: 06-2, Evaluated: 06-2) [Back to Table](#)

- E5. $CF_3 + O_2$.** Caralp et al.³ have measured the rate constant in N_2 between 1 and 10 Torr. This supersedes the value from Caralp and Lesclaux.² Kaiser et al.⁵ have extended the pressure range to 580 Torr measuring the reaction relative to the reaction of CF_3 with Cl_2 . Breheny et al.¹ report values at 295 K from 2–110 Torr and they make a cogent argument for lowering the value of the rate constant used by Kaiser et al for their reference reaction by about 50%. This has the effect of lowering the Kaiser values. Each study recommends different parameters, but the data are well represented by the currently recommended values. Data of Ryan and Plumb⁶ are in general agreement. Forst and Caralp⁴ have examined this reaction theoretically. (Table: 06-2, Note: 06-2, Evaluated: 06-2) [Back to Table](#)

 - (5) Kaiser, E. W.; Wallington, T. J.; Hurley, M. D. Kinetic study of the reaction of chlorine atoms with CF_3I and the reactions of CF_3 radicals with O_2 , Cl_2 and NO at 296 K. *Int. J. Chem. Kinet.* **1995**, *27*, 205-218.
 - (6) Ryan, K. R.; Plumb, I. C. Kinetics of the reactions of CF_3 with $\text{O}(^3\text{P})$ and O_2 at 295 K. *J. Phys. Chem.* **1982**, *86*, 4678-4683, doi:10.1021/j100221a008.
- E6. $\text{CF}_3\text{O} + \text{NO}_2$.** Fockenberg et al.² report values (and large error limits) in nitrogen with $250 < T/\text{K} < 302$ and $7 < P/\text{mbar} < 107$. Their values, including two sigma errors are: $k_0 = (3.1 \pm 3.0) \times 10^{-28}$; $n = (2.0 \pm 2.0)$; $k_\infty = (1.5 \pm 0.5) \times 10^{-28}$; $m = (2.8 \pm 2.0)$. Because such large values for m are not physically justifiable, the recommendation is based on a fit forcing $m=1$, which falls within the large error limits. The reaction products reported by Fockenberg et al. agree with those reported by Chen et al.,¹ who used photolysis of CF_3NO to prepare CF_3O_2 and subsequently CF_3O in 700 Torr of air at 297 ± 2 K. They considered two product channels: (a) CF_3ONO_2 obtained via three-body recombination and (b) $\text{CF}_2\text{O} + \text{FNO}_2$ obtained via fluorine transfer. Both products were observed and found to be thermally stable in their reactor. They report $k_a/(k_a+k_b) > 90\%$ and $k_b/(k_a+k_b) < 10\%$, thus the formation of CF_3ONO_2 is the dominant channel at 700 Torr and 297 K.

- E7. $\text{CF}_3\text{O}_2 + \text{NO}_2$.** The data are from experiments in O_2 of Caralp et al.,¹ who suggest a somewhat different fitting procedure than used here. A statistical best fit to the data yields a value of $m = 5.7$, but the values recommended here fit the data just about as well. Destriau and Troe² use yet a different fitting procedure that does not represent the data quite as well as that recommended here. Reverse rate data are given by Köppenkastrop and Zabel.³

- E8. $\text{CF}_3\text{O} + \text{CO}$.** Values taken from Turnipseed et al.¹ The numbers were obtained for Ar as the bath gas and are assumed to hold for N_2 as well. The temperature dependence of the high-pressure rate constant was determined over the range $233 < T/\text{K} < 332$ in SF_6 . No temperature dependence of the low-pressure-limiting rate constant was reported. The value in the table is an estimate. Wallington and Ball² report values in good agreement with Turnipseed et al.¹

Phys. Chem.* **1995**, *99*, 3201-3205, doi:10.1021/j100010a034.
- E9. $\text{CF}_3\text{O} + \text{M}$.** The activation energy for thermal decomposition of CF_3O to $\text{CF}_2\text{O} + \text{F}$ has been reported to be 31 kcal mol^{-1} by Kennedy and Levy.¹ Thermochemical data yield $\Delta H^\circ(298) = 23$ kcal mol^{-1} . This implies an intrinsic barrier of about 8 kcal mol^{-1} to elimination of F from CF_3O . Electronic structure calculations by Li and Francisco² support this observation. Adopting the A-factor for unimolecular dissociation, $A = 3 \times 10^{14} \text{ s}^{-1}$ and $E = 31$ kcal mol^{-1} from Kennedy and Levy, $k_\infty(298 \text{ K})$ is about $6 \times 10^{-9} \text{ s}^{-1}$. This corresponds to a lifetime of about 6 years; therefore, thermal decomposition of CF_3O is unimportant throughout the atmosphere.

F1. Cl + O₂. Nicovich et al.³ measured the rate constant at 181 < T/K < 200 and 15 < P/Torr < 40 in O₂. They reported $k_0 = (9 \pm 3) \times 10^{-33} \text{ cm}^6 \text{ molecule}^{-2} \text{ s}^{-1}$ at $T = 187 \pm 6 \text{ K}$ in O₂. The recommended low pressure limiting parameters are from fitting their data over the entire range and assuming that O₂ and N₂ bath gases are equivalent. The value from the calculation at 300 K (i.e., $2.2 \times 10^{-33} \text{ cm}^6 \text{ molecule}^{-2} \text{ s}^{-1}$) compares with an older value of Nicholas and Norrish² of 1.7×10^{-33} in an N₂ + O₂ mixture. Baer et al.¹ report a value in O₂ of $k_0 = 1.6 \times 10^{-33} (T/300)^{-2.9} \text{ cm}^6 \text{ molecule}^{-2} \text{ s}^{-1}$ in good agreement with the value recommended here. They also report a value in N₂ of $k_0 = 1.4 \times 10^{-33} (T/300)^{-3.9} \text{ cm}^6 \text{ molecule}^{-2} \text{ s}^{-1}$. A theoretical study by Zhu and Lin⁴ suggests $k_0 = 1.26 \times 10^{-16} T^{-6.22} \exp(-943/T) \text{ cm}^6 \text{ molecule}^{-2} \text{ s}^{-1}$ in O₂ (2.0×10^{-33} at 300 K) with $k_\infty(300) = 1.8 \times 10^{-10} \text{ s}^{-1}$, which is adopted here. The Nicovich et al.³ data are so far from the high pressure limit, that the rate constant has little sensitivity to k_∞ . Baer et al.¹ suggest $k_\infty = 2.7 \times 10^{-11} \text{ s}^{-1}$, but the data suggest a higher value.

F2. Cl + NO. Low-pressure limit and temperature dependence is from re-evaluation of data from Lee et al.³ The recommendation is also in good agreement with the data reported by Clark et al.² and by Ashmore and Spencer.¹

(Table: 06-2, Note: 06-2, Evaluated: 06-2) [Back to Table](#)

F3. Cl + NO₂. Low-pressure limit at 300 K from Leu⁴ and Ravishankara et al.⁷ The latter study extended the data to 200 Torr in He. A turbulent flow study by Seeley et al.⁹ extended the results to 250 Torr of Ar and the high-pressure limit was chosen to fit these two studies after taking into account differences in collisional efficiencies of the bath gases. Leu⁴ confirms the observation of Niki et al.⁵ that both ClONO and ClNO₂ are formed, with the former dominating. This has been explained by Chang et al.,¹ with detailed calculations in Patrick and Golden.⁶ The temperature dependence is as predicted in Patrick and Golden⁶ and is the same as Leu's results in He. Ravishankara et al.⁷ report a few data points in N₂ that may suggest a somewhat higher temperature dependence. The temperature dependence of the high-pressure limit is estimated. The uncertainty limits are estimated. Master Equation/RRKM studies by Zhu and Lin¹⁰ and by Golden,² using potential energy surfaces computed by Lee,³ Zhu and Lin,¹⁰ and Sayin and McKee⁸, report differences in their ability to fit the data. Zhu and Lin¹⁰ claim to fit, while Golden² finds the calculations to under predict the low pressure data.

- F8. ClO + NO₂.** The low-pressure-limit recommendation and uncertainties are based on temperature-dependent values from Zahniser et al.,¹³ Lee et al.,⁸ Birks et al.,¹ Leu et al.,⁹ Wallington and Cox,¹² Cox et al.,² and Molina et al.¹⁰ All of these data were collected in N₂ bath gas, except for several points from Lee et al.⁸ collected in O₂. The high-pressure-limit recommendation is based on the RRKM calculations of Smith and Golden.⁶ There are several pressure-dependent data sets in the literature, such as Percival et al.,¹¹ Handwerk and Zellner,⁷ Dasch et al.,⁴ and Cox and Lewis;³ however, they are too disparate to extract unambiguous values. These data are all reproduced within two-sigma error limits by the current recommendation. However, the value of m = 1.9 is somewhat large for a radical-radical process. If m = 1 is chosen the computed rate constant is lower by about 20% at 180 K and pressures above 500 Torr. Golden⁵ has attempted to fit the data with a master equation analysis and finds that the usual energy transfer treatment at low pressures is insufficient to fit the data.

F9. OCIO + NO₃. Friedl et al.² studied this system at $1 \leq P/\text{Torr} \leq 5$ for helium and $220 \leq T/\text{K} \leq 298$. They deduced values for the rate constant consistent with their data of $k_0 \approx 10^{-31}$ and $k_\infty \approx 10^{-11}$. They also suggest a value for the equilibrium constant: $K/\text{cm}^3 \text{ molecule}^{-1} = 1 \times 10^{-28} \exp(9300/T)$. Boyd et al.¹ raised the question of possible heterogeneous effects in this system. Parthiban et al.³ in a theoretical study, support the finding of Friedl et al.² of the species O₂ClONO₂, but suggest a very different equilibrium constant. (See Table 3-1).

F10. ClO + ClO. The recommendation is based on a global non-linear least squares fit (all data were assumed to have the same relative error) of data from Sander et al.¹⁵ (195–247 K), Nickolaisen et al.¹³ (260–390 K), Bloss et al.³ (183–245 K), Troler et al.¹⁹ (200–263 K), Boakes et al.,⁴ and Ferracci and Rowley⁷ (250–312 K). The Troler et al. data have been corrected for values at the zero pressure intercept as suggested in the Troler et al. paper. With this adjustment most of the data are in reasonable agreement. Boakes et al.⁴ report higher values and a zero pressure intercept; they suggest disregarding their data at less than 100 Torr and report preferred parameters of 2.79×10^{-32} ; 3.78; 3.44×10^{-12} ; 1.73. Ferracci and Rowley⁷ studied the reaction only at 760 Torr and found values in agreement with those of Boakes et al. The error limits represent an attempt to include most of the data within the 95% uncertainty band. The major dimerization product is chlorine peroxide (Birk et al.,² DeMore and Tschuikow-Roux,⁶ Slanina and Uhlik,¹⁶ Stanton et al.,¹⁷ and Lee et al.¹¹). Golden⁸ has performed RRKM and master equation calculations using the potential energy surface in Zhu and Lin²¹ and concluded that while a channel to form ClOClO might exist, the net yield is probably very small the best representation of the data remains that only a single channel is important. The k_0 value for N₂ is not in accord with a simple theory as explained in Patrick and Golden¹⁴ and in some detail in Golden⁸ (this finding was probably the result of a bug that was subsequently found in the master equation code). It has been suggested¹⁸ that the “radical-complex” mechanism may apply here, although a study by Liu and Barker¹² suggests otherwise. Other previous rate constant measurements, such as those of Hayman et al.,⁹ Cox and Derwent,⁵ Basco and Hunt,¹ Walker,²⁰ and Johnston et al.,¹⁰ range from $(1\text{--}5) \times 10^{-32} \text{ cm}^6 \text{ molecule}^{-2} \text{ s}^{-1}$, with N₂ or O₂ as third bodies.

F11. $\text{ClO} + \text{OCIO}$. Data are from Burkholder et al.,¹ who measured the rate constant in N_2 at $200 \leq T/\text{K} \leq 260$ and densities from $(1.1\text{--}10.9) \times 10^{18}$ molecules cm^{-3} . They also measured the equilibrium constant (See Table 3-1). Parr et al.³ also report a value for the rate constant in reasonable agreement with the recommendation. Zhu and Lin⁴ report an *ab initio* study of this system. Their parameters are somewhat different from those herein, but they fit the data equally well. Green et al.² report a value in He that is consistent with the values recommended herein.
(Table: 06-2, Note: 06-2, Evaluated: 06-2) [Back to Table](#)

F12. $\text{O} + \text{OCIO}$. The recommendation is based on data of Colussi et al.² and Colussi,¹ who measured the pressure dependence between 248 and 312 K in Ar. They interpret the intercept of their k vs $[\text{M}]$ curves as a zero-pressure rate constant of $(1.6 \pm 0.4) \times 10^{-13}$ cm^3 molecule⁻¹ s⁻¹ with a negative activation energy corresponding to a chemical activation channel producing $\text{ClO} + \text{O}_2$. This interpretation is supported by a low pressure study by Gleason et al.,³ as well as a theoretical study by Zhu and Lin,⁴ which suggests a direct abstraction with a positive activation energy. (Zhu and Lin⁴ point out that sym- ClO_3 has a positive barrier for dissociation to $\text{ClO} + \text{O}_2$.) The recommended values are fit to the data after subtracting the abstraction channel. See Table 1-1.

- F15. $CCl_3 + O_2$.** The recommendation incorporates studies by Fenter et al.,³ Danis et al.,² and Luther et al.⁵ (The data of Luther et al. above 100 bar are affected by slow diffusion.) Experimental data of Ryan and Plumb⁸ have been considered in the evaluation. A study by Nottingham et al.,⁶ in He, is in agreement. Forst and Caralp⁴ have examined this reaction theoretically. A Patrick and Golden-type calculation using the thermochemistry of Russell et al.⁷ yields $k_0^{300} = 1.5 \times 10^{-30}$, with $\beta = 0.3$. A value of $k_\infty^{300} = 5 \times 10^{-12}$ has been reported by Cooper et al.¹ The value of the rate constants recommended here differ only slightly from those of Luther et al., (who report $k_\infty^{300} = 5.2 \times 10^{-12}$; $m = 1.4$ and $k_0^{300} = 1.5 \times 10^{-30}$; $n = -6.3$; $F_c = 0.35 \times (T/300)^{-0.35}$ using the IUPAC formula) but yield an overall rate constant within their error limits.

 - (2) Forst, W., and F. Caralp Microcanonical variational theory of radical recombination by inversion of interpolate partition function Part 2.- $\text{CX}_3 + \text{O}_2$ (X = H, F, Cl). *J. Chem. Soc. Faraday Trans.* **1991**, 87, 2307-2315.
- F17. $\text{CF}_2\text{Cl} + \text{O}_2$.** The recommended $k_0(300)$ and $k_\infty(300)$ are from the experimental work reported by Codnia and Azcárate,¹ and the recommended temperature exponents are taken from the theoretical predictions of Forst and Caralp.² Codnia and Azcárate used CO_2 laser IR multiphoton dissociation of CF_2Cl_2 to prepare CF_2Cl radicals in the presence of O_2 (and N_2 buffer gas) at 300 K. Subsequent fast reactions produced vibrationally excited CF_2O^* , which they monitored by measuring its spontaneous IR fluorescence near 1928 cm^{-1} . They showed that the growth and decay rates of the IR fluorescence intensity are due to the reactions of CF_2Cl radicals with O_2 and to the rate of collisional deactivation of CF_2O^* . Analysis of the reaction rates between CF_2Cl and O_2 revealed the existence of both the pressure-dependent recombination reaction and a direct bimolecular step (previously proposed by other workers; see Table 1-1) are important in the pressure range from 0 to 20 mbar of N_2 . Separate control of O_2 concentrations enabled them to obtain the rate constant for the direct reaction (Table 1-1), as well as $k_0(300)$ and $k_\infty(300)$ for the recombination. The latter values are in rough agreement with the theoretical predictions of Forst and Caralp,² who predicted temperature exponents in approximate agreement with similar reactions. The estimated errors are relatively large because the reaction has been measured only once at 300 K and because the temperature dependence is based on theoretical predictions.

G1. Br + NO₂. The recommended values are from a study by Kreutter et al.² They regarded the product as BrNO₂. Their k₀ value in He agrees with the measurement of Mellouki et al.⁴ at 300 K. Broske and Zabel¹ and Orlando and Burkholder⁵ have shown that *cis*-BrONO is the major product in their studies. Orlando and Burkholder⁵ suggest that isomerization to BrNO₂ is heterogeneous. Lee³ calculated structure, frequencies and energetics for BrNO₂, *cis*-BrONO and *trans*-BrONO. A Patrick-and-Golden-type calculation using the Lee³ results yields k₀(strong collision) ≈ 1.2, 2.5, and 2.1 in units of 1 × 10⁻³¹ cm⁶ molecule⁻² s⁻¹ for *trans*-BrONO, *cis*-BrONO, and BrNO₂, respectively. The sum, 5.9 × 10⁻³¹, multiplied by a collision efficiency in N₂ of 0.3 is a factor of about 2.5 lower than the observed k₀ value. Also, the relative yield of BrNO₂ is somewhat too high since Orlando and Burkholder⁵ measure BrONO > 75%. Kreutter et al.² report an equilibrium constant, which, if *cis*-BrONO is assumed to be the product, suggests bond strengths for the BrONO compounds that are about 4 kcal mole⁻¹ higher than the Lee³ calculation. Computing k₀ with these new values yields k₀ ≈ 4.5 and 6.4 in units of 1 × 10⁻³¹ for *trans*-BrONO and *cis*-BrONO, respectively. When the sum of the rate constants for the three channels is multiplied by the collision efficiency (0.3), the result is 3.9 × 10⁻³¹ and the yield of BrONO is 85%.

G2. BrO + NO₂. Recommended values are from a global least squares fit of data from Thorn et al.¹⁰ and Sander et al.⁹, which are in excellent agreement at 298 K. The recommended values differ only slightly from the previous recommendation. Danis et al.¹ give slightly lower values for the low-pressure-limiting rate constant and a smaller temperature dependence as well. This latter study may be hampered by heterogeneous effects, but can be accommodated within the error limits recommended. A theoretical study by Rayez and Destriau⁸ suggests that the bond-dissociation energy in BrONO₂ is 8.5 kcal mol⁻¹ higher than in ClONO₂, thus rationalizing the relative values of the low-pressure-limiting rate constants for these two processes. A more detailed theoretical study by Parthiban and Lee,⁶ as well as a study by Orlando and Tyndall,⁵ who measured BrONO₂ decomposition and thus an equilibrium constant, both determine only 1.6 kcal mol⁻¹ for the above difference. A theoretical study by Zou et al.¹² agrees with the latter figure. A Patrick and Golden⁷ type calculation, even with the stronger bond of Rayez and Destriau⁸ yields a value for the low pressure limiting rate constant that is smaller than observed. Lessar et al.⁴ calculate a potential energy surface for BrOONO. They find that the BrO-ONO bond strength is of the order of 7 kcal mol⁻¹, which is too weak to have any effect on the overall rate of BrO + NO₂. Walsh and Golden^{2,11} have attempted to fit the data with a master equation analysis and found that the usual energy transfer treatment at low pressures is insufficient to fit the data (this was probably due to a bug that was found in that version of the master equation code). Kreycky et al.³

analyzed atmospheric data and concluded that the recombination rate constant needed to fit the data near 200 K is smaller than the (previous) recommendation.

G3. $\text{Br} + \text{CH}_2=\text{CHCH}=\text{CH}_2$ (1,3-butadiene). In a comprehensive study of the forward and reverse rates of this reaction (using laser flash photolysis of CF_2Br_2 precursor and atomic resonance fluorescence detection of Br-atoms), Laine et al.² determined the recombination rate constant from 227 to 298 K. The products are thought to consist of two isomers, but they were not identified in the experiments. Calculations (G4 method) reported by Laine et al. show that addition of Br to a terminal carbon atom is thermodynamically favored. The rate constants reported by Laine et al.² are about $2\times$ as large as relative measurements at 298 K and 1 bar reported previously by Bierbach et al.¹ Bierbach et al. placed their rate constant on an absolute basis by employing a linked chain of relative rate measurements, which consisted of reactions of Br with 2,3-dimethyl-2-butene, trans-2-butene, propene, and terminated with an absolute rate constant for Br + acetaldehyde; thus the uncertainties may have accumulated. The current recommendation is based on the parameters measured in the direct experiments of Laine et al.² The recommended 2σ error bars encompass all of the data of Laine et al.

- (1) Bierbach, A.; Barnes, I.; Becker, K. H. Rate coefficients for the gas-phase reactions of bromine series of radicals with alkenes, dienes, and aromatic hydrocarbons at 298 ± 2 K. *Int. J. Chem. Kinet.* **1996**, 28, 565-577.
- (2) Laine, P. L.; Sohn, Y. S.; Nicovich, J. M.; McKee, M. L.; Wine, P. H. Kinetics of elementary steps in the reactions of atomic bromine with isoprene and 1,3-butadiene under atmospheric conditions. *J. Phys. Chem. A* **2012**, 116, 6341-6357, doi:10.1021/jp212127v.

G4. $\text{Br} + \text{CH}_2=\text{C}(\text{CH}_3)\text{CH}=\text{CH}_2$ (isoprene). In a comprehensive study of the forward and reverse rates of this reaction (using laser flash photolysis of CF_2Br_2 precursor and atomic resonance fluorescence detection of Br-atoms), Laine et al.² determined the rate constant from 227 to 298 K. The products may consist of several isomers; calculations (G4 method) reported by Laine et al. show that the energetically most stable isomer is $\text{BrH}_2\text{CC}(\text{CH}_3)\text{CH}=\text{CH}_2$, but the identities of the isomers actually produced in the reaction are not known. Laine et al. also measured the rate constants for the reaction of Iso-Br + O_2 (see Table 1-1) and for the reaction of Br + 1,3-butadiene in both the presence and absence of O_2 . They found that the apparent rate of the latter reaction is affected by the presence of O_2 . Bierbach et al.¹ previously reported relative rate constants at 298 K and 1 bar of air. They placed their rate constants on an absolute basis by employing a linked chain of five relative rate measurements, consisting of reactions of Br with 1,3-butadiene, 2,3-dimethyl-2-butene, trans-2-butene, propene, and terminated with an absolute rate constant for Br +

acetaldehyde; thus the uncertainties may have accumulated. The current recommendation is based on the parameters measured in the direct experiments of Laine et al.² in the absence of O₂. The recommended 2σ error bars encompass all of the data of Laine et al.

H2. I + NO₂. Evaluation taken from IUPAC.² The data are from van den Bergh et al.,⁵ Mellouki et al.,³ Buben et al.,¹ and van den Bergh and Troe.⁶ IUPAC uses F_c = 0.63, which is essentially the same as the universal value adopted here of F_c = 0.6. (No evidence of possible isomers [INO₂ or IONO] is reported.) Error limits transposed to the current format. Tucceri et al.⁴ used laser flash photolysis coupled to resonance-fluorescence detection of I atoms to measure the rate coefficients for the reaction: I + NO₂ + M → INO₂ + M. Rate coefficients at 298 K when combined with other datasets obtained at higher and lower pressures, were adequately described by a simplified Troe function with the parameters: k₀(He, 330 K) = 1.48 × 10⁻³¹ cm⁶ molecule⁻² s⁻¹, F_c(He) = 0.43, and k_∞ = 1.1 × 10⁻¹⁰ cm³ molecule⁻¹ s⁻¹ for He as bath gas. In N₂ (or air) the following parameters were obtained k₀(N₂, 300 K) = 3.2 × 10⁻³¹ cm⁶ molecule⁻² s⁻¹, F_c(N₂) = 0.48, with k_∞ = 1.1 × 10⁻¹⁰ cm³ molecule⁻¹ s⁻¹. These parameters essentially reproduce the values at 300 K from the parameters in the Table.

H3. IO + NO₂. Data from Daykin and Wine,² Hölscher and Zellner,⁵ Allan and Plane,¹ Jenkin and Cox,⁶ and Dillon et al.³ are considered. Dillon et al. suggest that the value from Hölscher and Zellner might be low at 298 K due to regeneration of IO, although their values at lower temperatures are in agreement with others. The recommendation takes this into consideration and accommodates the rest of the data. Two more studies at lower pressures are available, Larin et al.⁸ and Maguin et al.⁹ These latter do not agree very well with the above five studies and have larger experimental errors. The recommended k₀ and k_∞ also agree with a theoretical study by Rayez and Destriau.¹² A computational study by Marshall¹⁰ sets the bond dissociation energy as ΔH₀(IO-NO₂) = 113.6 ± 3.1 kJ mol⁻¹ and suggests k₀ = (5.3–13.3) × 10⁻³¹ cm⁶ molecule⁻¹ s⁻¹ for N₂ as the bath gas, while an ME/RRKM study by Golden⁴ required ΔH₀(IO-NO₂) ~150 kJ mol⁻¹ to fit the data. Papayannis and Kosmas¹¹ compute ΔH₀(IO-NO₂) = 137.6 or 131.7 kJ mol⁻¹, depending on spin orbit coupling corrections in IO. A computational study by Koltsoyannis and Plane⁷ concludes that ΔH₀(IO-NO₂) = 117.9 kJ mol⁻¹. See Table 3-1 for the recommended K_{eq}. (Table: 10-6, Note: 10-6, Evaluated: 10-6) [Back to Table](#)

H4. CH₂I + O₂. The recommendation at 298 K is the average of measurements by Masaki et al.,⁵ Eskola et al.,² Huang et al.,³ Sheps,⁶ and Stone et al.⁷ Evidently, there is no pressure dependence up to at least 1 atm. The recommendation for the temperature dependence is taken from Eskola et al.² Among other products, this reaction produces significant yields of thermalized formaldehyde oxide (CH₂OO, the simplest carbonyl oxide, also known as a Criegee Intermediate).¹ Yields of CH₂OO in this reaction under one atmosphere of air near 300 K have been reported to be 0.15 ± 0.03,^{3,4} ~0.18,⁷ and ~0.30.⁸

I1. HS + NO. Data are from the work of Black et al.¹ The temperature dependence of k_∞ has been estimated and k₀ has been adjusted to fit the data.

(Table: 06-2, Note: 06-2, Evaluated: 06-2) [Back to Table](#)

- (1) Black, G.; Patrick, R.; Jusinski, L. E.; Slinger, T. G. Rate coefficients for the reaction $\text{HS} + \text{NO} + \text{M}$ ($\text{M} = \text{He}$, Ar , and N_2) over the temperature range 250–445 K. *J. Chem. Phys.* **1984**, *80*, 4065–4070.
- 12. $\text{CH}_3\text{S} + \text{NO}$.** The recommended values are fit to the study by Balla et al.¹ The temperature range was 295 to 453 K and pressures of N_2 from 1.5 to 300 Torr. The recommended high pressure limiting rate coefficient and temperature dependence provide a better fit to the data than reported by Balla et al.
(Table: 06-2, Note: 06-2, Evaluated: 06-2) [Back to Table](#)
- (1) Balla, R. J.; Nelson, H. H.; McDonald, J. R. Kinetics of the reaction of CH_3S with NO , NO_2 and O_2 . *Chem. Phys.* **1986**, *109*, 101–107.
- 13. $\text{O} + \text{SO}_2$.** Naidoo et al.⁴ studied this spin-forbidden reaction in Ar over the temperature range $290 < T/\text{K} < 840$ and pressure range $100 < P/\text{mbar} < 880$. They fit the data very well using the IUPAC¹ format with $k_0 = 9.5 \times 10^{-23} \text{ T}^{-3} \exp(-2400/T) \text{ cm}^6 \text{ molecule}^{-2} \text{ s}^{-1}$, $k_\infty = 6.1 \times 10^{-13} \exp(-850/T) \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ and $F_c = 0.558 \exp(-T/316) + 0.442 \exp(-T/7442)$. The recommended values transpose the rate constants to the form used in this evaluation and are used with the standard value of $F_c = 0.6$. These parameters do not fit the higher temperatures as well as the values derived by Naidoo et al. (i.e. missing the values at 840 K by about 50% and those at 699 K by about 20%), but values at 289, 399 and 581 K are fit quite well and are adequate for atmospheric conditions. Earlier values are reported by Atkinson and Pitts² and Müller et al.³

- 14. $\text{OH} + \text{SO}_2$.** Values of the rate constant as a function of pressure and temperature are from Blitz et al.⁴ They used a five parameter fit to the data, allowing F_c to be temperature dependent. The values of k_0 and k_∞ have been adjusted in the Table to accommodate $F_c = 0.6$. Blitz et al.⁴ determined the high pressure limit from the reaction of $\text{OH}(v=1)$ with SO_2 . Their low pressure value was taken by re-evaluating the data of Wine et al.⁹ in various bath gases at pressures up to 150 Torr and temperatures between 260 K and 420 K, through the use of a master equation. The data of Paraskevopoulos et al.⁸ in the same pressure range, are equally well fit. Lower pressure data from at 298 K from Leu⁶ and Lee et al.⁵ are well accommodated by the recommendation herein. Earlier data listed in Baulch et al.,³ Baulch et al.,² and Atkinson et al.¹ are noted. Blitz et al.⁴ have calculated the entropy and measured a third law heat of formation for HOSO_2 ($373 \pm 6 \text{ kJ/mol}$). See also Li and McKee.⁷

- I5. $\text{CH}_3\text{S} + \text{O}_2$.** The Panel makes no recommendation, since only one direct measurement of the rate constant has been reported and helium bath gas is not appropriate for the atmosphere. The following is for information, only.
- Turnipseed et al.⁴ generated CH_3S radicals by pulsed laser photolysis of CH_3SCH_3 with O_2 in excess and used LIF of CH_3S to monitor the subsequent reaction. Biexponential decays were observed, signaling the reversible formation of a weakly bound complex. They obtained forward and reverse rate constants in 80 Torr of He bath gas at temperatures from 216 to 250 K; the values of $K_{\text{eq}} = k_{\text{rec}}/k_{\text{uni}}$ are in good agreement with the recommended K_{eq} (see Table 3-1). Assuming that k_{rec} is near the low pressure limit, the data of Turnipseed et al. are described by $k_0(T) = 8 \times 10^{-32} (T/298)^{-5.7}$ in helium bath gas. The reaction has been implicated in three indirect studies,¹⁻³ which reported estimated ratios of rate constants.

Phys. Chem.* **1993**, *97*, 8442-8449.
- I7. $\text{SO}_3 + \text{NH}_3$.** Recommendation is from Lovejoy.¹ This study covered 20–80 Torr from 280–340 K. An earlier study by Lovejoy and Hanson,² who studied this reaction from 10–400 Torr N_2 at 295 K is in agreement. Lovejoy and Hanson² observed that any incipient adduct rapidly becomes sulfamic acid (H_3NSO_3) which clusters efficiently with itself and sulfuric acid. The observed sulfamic acid dimerization rate constant exceeds $5 \times 10^{-11} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$. Measurements of Shen et al.³ at 1–2 Torr He are much higher than those of Lovejoy and Hanson² or Lovejoy.¹ Error limits have been adjusted to take into account the fact that the exponent of the temperature dependence of the low pressure rate constant is unusually large. Lovejoy¹ also reports an equilibrium constant and heat of formation of sulfamic acid of $-24 \pm 1 \text{ kcal mol}^{-1}$.

- I8. $\text{HO} + \text{CS}_2$.** The data are from Hynes et al.³ and Murrells et al.⁴ The value $m = 1$ is constrained. The recommended rate constant is in reasonable agreement with the measurement of Bulatov et al.¹ Petris et al.² report experimental detection of CS_2OH . See Table 3-1 for the recommended equilibrium constant. The adduct reacts slowly with O_2 . (See Table 1-1).
- (Table: 06-2, Note: 15-10, Evaluated: 06-2) [Back to Table](#)

- I9. Cl + CS₂.** The data are from Nicovich et al.² Wallington et al.³ have also studied this system. The value m = 0 is constrained. Nicovich et al.² confirm that the reaction proceeds via reversible adduct formation as suggested by Martin et al.¹ The much larger rate constant values determined by Martin et al. may possibly be attributed to reactive impurities in the CS₂ sample. Nicovich et al. set an upper limit on the rate constant for the adduct (CS₂Cl) reacting with O₂ of 2.5 × 10⁻¹⁶ cm³ molecule⁻¹ s⁻¹ at room temperature. Wang and Phillips⁴ have reported a theoretical study of the adduct.

- I10. OH + CH₃SCH₃ → (CH₃)₂SOH → products.** The OH + CH₃SCH₃ reaction is complex, proceeding by both direct H-abstraction and reversible addition pathways. A recommendation for the direct reaction is discussed separately in Table 1-1. The product of the reversible addition pathway reacts with O₂ creating an irreversible path as well. Mechanistically, this pathway is described by combining the rate constants k_f for the addition step, k_r for the reverse dissociation step, and k_{O2} for the adduct reaction with O₂. This is discussed in detail in the notes for Table 1-1. The equilibrium constant for the reversible addition process is K_c = k_f/k_r. Recommendations for K_c and k_{O2} are found in Tables 3-1, and 1-1, respectively. The value for k_f recommended here is from Williams et al.¹ The discussion in Table 1-1 points out that this value taken with K_c and k_{O2} fits the extant data very well.
(Table: 10-6; Note: 10-6; Evaluated: 10-6) [Back to Table](#)

Phys. Chem. A* **2009**, *113*, 6697-6709, doi:10.1021/jp9010668.
- I11. Cl + (CH₃)₂S.** [See Table 1-1] If the HCl yield at 297 K from Stickel et al.⁴ is used as a measure of the abstraction reaction, the rate constant would be 1.64 × 10⁻¹⁰ cm³ molecule⁻¹ s⁻¹. Using this value the complete data set from Stickel et al.⁴ can be fit with the form used in Table 2-1 with the addition of a term for the abstraction in the form k_{abs} = 1.64 × 10⁻¹⁰(T/300)^a. The value of "a" obtained in this manner is almost zero, so the data are fit with: k₀ = 4 × 10⁻²⁸(T/300)^{-7.0} and k_∞ = 2 × 10⁻¹⁰ (T/300)⁻¹ along with the temperature independent value of k_{abs}. These parameters are recommended herein. Enami et al.² propose k₀ = 2.2 × 10⁻²⁸ and k_∞ = 2.2 × 10⁻¹⁰ at 298 K along with k_{abs} = 1.8 × 10⁻¹⁰. On the other hand, a study by Diaz-de-Mera et al.¹ performed in the temperature range 259 < T/K < 364 and in helium at pressures of 0.5 < P/Torr < 1 reports a value k_{abs} = (2.0 ± 1.2) × 10⁻¹⁰ exp[-(332 ± 173)/T], which yields 6.6 × 10⁻¹¹ cm³ molecule⁻¹ s⁻¹ at room temperature. Several studies, both experimental by Urbanski and Wine⁵ and theoretical by Resende and De Almeida³ make it clear that at higher pressures an adduct Cl-S(CH₃)₂ is formed and this adduct does not yield CH₃ radicals or the products of the abstraction pathway.

- I12. Br + (CH₃)₂S.** Wine et al.⁵ data for the adduct formation in N₂ at 25 < P/Torr < 600 and 263 < T/K < 310 are the basis for the recommendation. Studies by Ingham et al.² and Nakano et al.⁴ are in agreement. Nakano et al.⁴ is also in agreement with the value of the equilibrium constant. However, Maurer et al.³ find a value at 300 K and 1 bar total pressure of a mixture of 5% O₂ and 95% N₂, only 2% as high as the value computed from the recommended parameters. This latter value is supported by Ballesteros et al.¹

- J1. Na + O₂.** A study by Plane and Rajasekhar³ finds $k_0 = (2.9 \pm 0.7) \times 10^{-30} \text{ cm}^6 \text{ molecule}^{-2} \text{ s}^{-1}$ at 300 K with $n = 1.30 \pm 0.04$. They also estimate k_∞ to be about $6 \times 10^{-10} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$ with a small positive temperature dependence. Another study by Helmer and Plane¹ yields $k_0 = (3.1 \pm 0.2) \times 10^{-30} \text{ cm}^6 \text{ molecule}^{-2} \text{ s}^{-1}$ at 300 K with $n = 1.52 \pm 0.27$. The recommended values are taken from these studies. They are consistent with values measured by Marshall et al.² at 600 K and those measured by Vinckier et al.⁵ at higher temperature. The k_0 value is about 60% higher than that of Silver et al.⁴

- J5. $\text{Hg} + \text{Br}$.** The recommendation is based on the direct experiments of Donohoue et al.,² who used pulsed laser photolysis of Br_2 to generate an excess of Br atoms, which reacted with Hg^0 vapor; the Hg^0 and atomic Br were monitored simultaneously by pulsed laser induced fluorescence techniques. The recombination reaction rate constant at the low pressure limit was measured in N_2 gas at temperatures from 243 to 293 K and N_2 pressures from 200 to 600 Torr (measurements were also carried out using He gas). In earlier studies, Greig et al.⁵ analyzed the UV spectrum of HgBr and used their measured absorption coefficients to determine the recombination rate constant from 393 K to 448 K in 200 Torr of CF_3Br (conditions not relevant to the atmosphere). Ariya et al.⁸ and Spicer et al.⁹ used relative rate techniques to obtain the rate constant, but both studies are discussed in detail by Donohoue et al.,² who concluded that they were seriously affected by secondary reactions. Several theoretical calculations have been reported.^{3,4,6,7} In particular, Goodsite et al.³ used spectroscopic data, quantum chemistry calculations, and RRKM modeling to show that the theoretical results are in reasonable agreement with experiments. Later, using a corrected bond dissociation energy, they repeated the calculations⁴ and showed that with a reasonable choice of an energy transfer parameter, the RRKM results are in very good agreement with the experiments of Donohoue et al.² A review of Hg atmospheric chemistry has appeared.¹
